The Special Representative Meeting showed beyond doubt that the majority of medical men are strongly opposed to some of the principal features of the Bill, the Second Reading of which was debated in the House of Commons last week. The power of the Minister to introduce by Regulations almost any change he wishes raises wide apprehension. We must, however, acknowledge that Mr. Aneurin Bevan appears to have resisted pressure from his own party as well as from the Negotiating Committee. Many members of the Labour Party in the House of Commons would have preferred a whole-time salaried State service, with no concessions to private practice. In his temperate exposition of the Bill Mr. Bevan showed himself willing to consider amendments at the Committee stage. The job of the profession is to press hard for those amendments which it considers to be essential to an ordered evolution of the medical services of this country.

From the nature of his work and the imperfect state of medical knowledge the doctor who is non-partisan in politics distrusts revolutionary changes in the forms of medical practice. The British Medical Association has been criticized for interpreting this Bill as the first and deliberate step towards a whole-time salaried State medical service. Mr. Bevan, it is true, has made provision for private practice in both the hospital and the home. In the debate he said: "Some of my hon. friends on this side of the House are in favour of a full salaried service. I am not. I do not believe that the medical profession is ripe for it."

Therefore the main source at the moment through which a general practitioner will obtain his remuneration will be capitation. When Mr. Reid observed that this indicated that "the Minister is out for a full-time salaried service as soon as he feels he can impose that upon the country," Mr. Bevan interjected, "There is all the difference in the world between plucking fruit when it is ripe, and plucking it when it is green." So the medical profession may be excused for feeling uneasy. Mr. Reid went on to ask whether the Labour Party's pamphlet, "A National Service for Health," published in April, 1943, still held good. He quoted this from it: "In the Labour Party's opinion it is necessary that the medical profession should be organized as a national full-time salaried pensionable service." Mr. Arthur Greenwood, the Lord Privy Seal, who wound up the debate, gave the answer: "What was published by my party in 1943, to which the Right Hon. and Learned Gentleman referred, we of course stand by. We have never repealed any of our policy, and we shall continue to march on in the light of that policy." However conciliatory the Minister may now be, the fate of the medical profession is sealed if the Labour Party remains in power long enough to carry out its declared policy. If the medical

profession, as we believe it does, regards a whole-time State service as harmful to the public and the profession, then it must do all it reasonably can to stop at its source a stream that threatens to become an inundation.

What chance is there of modifying the Labour Party's policy for a whole-time salaried State medical service, now we know from the Lord Privy Seal that this policy stands in spite of the provisions of the present Bill? In opposing this the profession fortunately has the strong support of the Parliamentary Secretary to the Ministry of Health, Alderman Key, who, having no vested interest in medicine, cannot be accused of this very wicked thing. In his able speech on May 1 he made two statements of the highest importance—statements which, when they have been made by medical spokesmen, have been derided by those who maliciously claim that doctors have no other concern in their profession than an economic one. Mr. Key said this: "We regard the free choice [of doctor] by the patients as being the more important principle, and, therefore, we put forward a compromise"—the compromise, that is, of paying general practitioners partly by salary and partly by capitation fee. Mr. Key's statement summarized the analysis of the situation previously made by Mr. Bevan: "There ought to be nothing to prevent anyone having advice from another doctor than his own." Mr. Bevan went on to say that if someone hears that a certain doctor in a certain place is good at this, that, or the other, he wants to "go along for a consultation." In response to interjections from his own side of the House, Mr. Bevan remarked that this was a field "in which idiosyncrasies are prevalent. If an individual wishes to consult, there was no reason why he should be stopped."

It is encouraging that the two principal Government spokesmen have not been misled by their own party propaganda on this question of free choice. We should add that no medical spokesman has ever pretended that free choice means unlimited free choice: the choice of any service or commodity is always limited by the circumstances of time and place. To assert that the limitation of choice means the absence of choice is partisan nonsense. Mr. Key carried the argument a significant step forward, thus: "*Second and more important, a full salaried service is inconsistent with the free choice of doctor, to which we have agreed* (Our italics). We have far too much respect for the political acumen and intelligence of Mr. Bevan and Mr. Key to believe that they have been persuaded to this view by what many of their supporters have ridiculed as B.M.A. propaganda. The Labour Party is in fact in a dilemma, and its two principal spokesmen in the debate last week had the courage to admit it. The Labour Party's dilemma is the doctor's dilemma—namely, how to reconcile the free choice of doctor with a whole-time salaried service. If both the medical profession and the Labour Party, approaching this problem from completely different standpoints, reach the same conclusion, then there must be something in it. The medical profession must, therefore, press for amendments to the Bill which will remove the Labour Party from the horns of their dilemma."

Mr. Key carried his analysis still further by relating the whole-time salaried service to direction: "A large salary," he observed, "cannot be paid irrespective of the work

than relieve symptoms, and help to keep the patient quiet and cheerful, so as to give Nature as free a hand as possible in the removal of the cause of his trouble. As for the medicinal substances with which pharmacological investigation chiefly concerned itself in those days, these were very apt to be chosen rather for the definiteness of their action, and for its accessibility to finer physiological analysis, than for any conviction as to their therapeutic importance. So it came about that many of the drugs which were regarded as most attractive for study by the pharmacologist owed their interest rather to the light which their actions were beginning to throw on problems of fundamental physiology than to their special importance in practical therapeutics. Those who were clinical students in those days will not fail to remember the air of cynical discouragement which some of the ablest physicians then adopted to most of the medicinal treatment at their disposal, and the aloofness of the teaching in the wards from what the pharmacologist was studying in his laboratory. This situation was accentuated for the time, rather than alleviated, by the appearance of early representatives of new kinds of remedies having nothing to do with the traditional *materia medica*, or with the conventional pharmacology concerned with these, originating in the discoveries of physiology and immunology—hormones, immune sera, and vaccines, remedies dealing directly with the causes of various disorders.

It was under these conditions that the desire arose for a new kind of impulse in pharmacology, and that the genius of Paul Ehrlich was found to give it direction, system, and a new name, "chemotherapy," to distinguish it from the pharmacology which he had found too academic for his practical aim. This aim was the discovery of new, artificial substances which would deal directly with the causes of infection, and would do so better than the few among the traditional remedies to which such an action could be attributed. The success of this campaign has produced one of the most dramatic among the many great changes in medical science and practice which the present century has witnessed. Salvarsan, germanin (suramin), atabrin (mepacrine), the sulphonamides, and now penicillin, represent wave crests on the rising tide of its achievement. With this successful exploitation of the products of synthetic chemistry for the direct removal of the causes of infection there has been a parallel activity in the provision by synthesis of new and better remedies for the alleviation of symptoms, which must still remain an important if secondary concern of treatment. In all directions pharmacology, with its vigorous offspring chemotherapy providing the scientific basis of medicinal treatment applied in a new atmosphere of well-grounded confidence, has moved into the centre of interest in medical research. It is well, then, that British pharmacologists should have their own journal, to give to the world the results of the growing volume of pharmacological researches which the universities, the Government, and industry may be expected to support. They have hitherto found hospitality for their publications in the journal which Abel founded in Baltimore, as well as in the weekly medical journals, and those devoted primarily to physiology and to pharmacy in their own

country. Their researches have surely attained an importance justifying a special journal to give them to the world, and the new venture should receive a hearty welcome. Its first number represents a full range of pharmacological interests, containing papers which deal with the elucidation of physiological problems by pharmacological methods, with new remedies for symptomatic treatment, and with others for chemotherapy in the stricter sense.

POST-MORTEM FINDINGS IN PREFRONTAL LEUCOTOMY

The operation of prefrontal leucotomy is still in an experimental stage. It has had some brilliant though partial successes. In the catatonic schizophrenic, violence and aggression that have persisted for years have given place to quiet and relatively human behaviour; and the chronic melancholic who has proved refractory to convulsion therapy has been restored to a state of well-being by having the white fibres of his frontal lobes cut. These benefits have had to be paid for with a diminution of some of the higher faculties, and in many cases the anticipated benefit has not been achieved. One of the most serious disadvantages of the operation has been the unpredictability of the results. It has long been recognized that this is partly because the operation is a blind one, and the extent and location of the intended destruction of white matter are not controlled. Post-mortem investigation of anatomical changes and their correlation with degree of improvement have been badly needed.

A beginning in this direction has now been reported by Meyer and Beck.¹ They have investigated 9 such cases with a tenth in which frontal lobectomy had been carried out for basal meningioma in a mentally normal patient. In 4 of these patients—3 schizophrenics and one psychopath—clinical improvement over 8–36 months was considerable, and death eventually occurred from unrelated causes. Two patients died within a week of the operation, and the other three showed no improvement; in one of them the improvement obtained was offset by a severe frontal lobe syndrome. The extent of the surgical lesion varied very greatly from case to case, and in the patients who improved tended to be less than in the others. In one case marked improvement resulted from a unilateral operation, and in another case with a good result the prefrontal region had not been involved. Extensive haemorrhage and a too posterior cut yielded unfavourable results. It seems that patients chronically ill and with much deterioration of personality did less well and required a more extensive severance of the fibres than others. Considerable improvement may take place without cutting the fasciculus cinguli or other midline structure, which had been considered by Freeman and Watts to be of importance in relation to recovery.

Pathological examination has disclosed interesting anatomical findings. Retrograde degeneration of the dorsal medial nucleus of the thalamus occurred in all cases in which thalamocortical fibres had been severed. Owing to the varying extent of the operation it was possible to gain detailed knowledge of the organization of the thalamocortical radiation, which, it was learned, is in the human brain similar to that in apes. Evidence was obtained that the thalamic radiation to the orbital areas of the prefrontal region is of considerable strength. In the prefrontal cortex anterior to the cut there was a slight reduction of the

number of nerve cells, particularly of the third layer. The centre median nucleus of the thalamus, which is thought to serve as a purely thalamic association centre, varies greatly from subject to subject, both in the normal and in the abnormal, and its possible significance to psychiatry calls for study.

The work of Meyer and Beck is of high interest to the neurosurgeon and the psychiatric therapist. But the chief lesson to be learned is that the operation of prefrontal leucotomy is a human experiment in which further study is urgently required. The brain of any patient who dies and is known to have had a prefrontal leucotomy should, wherever possible, be sent for examination to a recognized centre for neurohistology.

UNIFICATION OF PHARMACOPOEIAS

In May, 1945, when victory was won in Europe, the Health Organization of the League of Nations published an interim report¹ of a technical commission of pharmacopoeial experts on the steps which have been taken towards an International Pharmacopoeia. The project sounds as full of hope, and presents much the same difficulties, as that of setting up a United States of Europe. Not that there is difficulty in peacetime in getting an international committee together, but to persuade those of any nationality to surrender their own pet pharmacopoeial habits for the common good is a large undertaking. The Health Organization has, however, been very successful in the closely related field of biological standards, and the present report, published at the moment it was, augurs well for success in this field too.

It describes the conferences which have been held since 1902: these were responsible for the First and Second International Agreements for the Unification of the Formulae of Potent Drugs. The technical commission of pharmacopoeial experts was set up in 1937, it was formed after negotiation with the Belgian Government and in liaison with the International Pharmaceutical Federation. It has as its chairman Dr. C. H. Hampshire, the secretary of our own Pharmacopoeia Commission, and among its members is Dr. Fullerton Cook, representing the United States. It has produced what is in effect a skeleton pharmacopoeia containing no fewer than 47 monographs, all approved by the representatives of seven different countries. It gives a list of about 160 more substances at present being studied. This is an important achievement which should go far to convince those doubtful of the practicability of an international book of this kind. The need for it may perhaps not be fully realized here, but in Canada, for example, some unification of the *B.P.* and the *U.S.P.* would prove a godsend to the pharmacists who have to keep in line with both.

ATOMIC ENERGY IN MEDICINE

Prof. M. L. Oliphant, who was associated with Lord Rutherford in his early work on atomic disintegration, delivered the twenty-fifth Silvanus Thompson memorial lecture—Rutherford himself had delivered the first—to the British Institute of Radiology on April 11, and discussed, with due regard to the secrecy which still hangs over the subject, the uses of atomic energy, especially in biology and medicine. By the bombardment of atoms by protons and deuterons, he said, it was possible to transform almost

every chemical substance, changing it into a radioactive species possessing the property of emitting negatively charged electrons or alpha particles. The tracer elements, as they were called, were likely to play a great part in unravelling the complicated chemical processes which went on in biological phenomena. Some outstanding work had already been done whereby carbon dioxide was shown to be utilized by plants and the method of its transformation into sugars and cellulose, the structural material of the plants themselves, had been disclosed. There were now radioactive species of every chemical element in the periodic table, though it was true that some of them were not very useful, either because their life was far too short or their half-life times far too long. Most of them emitted negative electrons, one or two emitted positive. The process of splitting or fission of uranium was accompanied by a tremendous release of energy. The lecturer described experiments in the New Mexican desert, where, after the explosion of an atomic "bomb," an enormous area was depressed like a bowl and the sand became fused and took on a red colour, as evidenced in some specimen particles he handed round among the audience. The release of neutrons during such an explosion would sear and scorch everything with which they came in contact, and anyone exposed at a distance even of several miles might receive a lethal dose of radiation. Using the material in the form of sprays, it would be possible to contaminate, as if by poison gas, many hundreds of square miles of an enemy territory.

So much for the new plaything of the warmongers. On the other side of the account certain of these fission products, with a radioactivity very similar to that of radium, might be harnessed to industrial and clinical uses. The biological effect of the neutron was about five times that of the gamma rays of radium and gave the same kind of physical effect—namely, ionization. Prof. Oliphant exhibited plans of apparatus for the production and distribution of these radioactive materials for agricultural, chemical, metallurgical, and clinical uses. The centres, he said, should preferably be based on a university, with laboratories for the production of radioactive materials in the form required for these purposes. With what was known as the Harwell pile, consisting of rods of uranium arranged in lattice form, the spaces between the rods being filled with a substance like graphite, it was possible to generate the equivalent of 30 curies or more a day. Nuclear physics, he said, had now developed until it was ready to become a source of radioactive materials in almost unlimited quantities. Sources of neutrons were available which, because of the peculiarity of the ionization they produced in the tissues, were worthy of full investigation as alternatives to x rays and radium. It was possible to make a very good substitute for radium, and to produce it in immense quantities far beyond the world's radiotherapeutic needs. Prof. Oliphant concluded his lecture with the remark, "I think the indications are that the price of radium is going to fall."

We regret to announce the death in New York at the age of 83 of Dr. Simon Flexner, the distinguished bacteriologist and Director Emeritus of the Rockefeller Institute for Medical Research. He was a Foreign Corresponding Member of the British Medical Association.

The next session of the General Medical Council will open on Tuesday, May 28, at 2 p.m., when the President, Sir Herbert Eason, will take the chair and deliver an address.

¹ *Bulletin of the Health Organisation of the League of Nations*, vol. XII, Extract No. 4, 1945-6.

THE PUBLIC AND THE BILL

DR. HILL'S ADDRESS AT GOLDERS GREEN

A largely attended public meeting, arranged by the Hendon Division of the B.M.A., was held at Golders Green Hippodrome on Sunday, May 5, when an address on the National Health Service Bill was given by Dr. Charles Hill, Secretary of the Association. The chair was taken by Sir Alfred Webb-Johnson, P.R.C.S., who was accompanied on the platform by the officers and other prominent members of the Division. Some 1,500 people were present.

The chairman said that the profession as a whole was behind the objective of this and previous Governments in seeking a comprehensive health service, but felt that objection must be taken to some of the proposals. The general practitioner, so long as there was free choice of doctor, built up goodwill in his practice, but one of the proposals was that he should be entitled no longer to regard that goodwill as his own. The tribunals to be set up might deprive a practitioner of the right to accept public patients, although the General Medical Council retained his name on the *Register*. The practitioner, if not already established in an area, was required to obtain permission to practise in it, yet ever since Magna Carta it had been the right of the citizen to follow his employment how, when, and where he wished. The proposals amounted to this, that the Minister had power to create an absolute State monopoly of practice. (A voice: "About time, too.")

Surrender of the Hospitals

Dr. Hill dealt first with the hospital proposals. The Minister of Health, in his opening speech on the Second Reading—a speech which in large part was statesmanlike and conciliatory—had surveyed the hospital position, and with much in his diagnosis all would agree. There was need for the marriage of voluntary and council hospitals into one service which would represent the best features of both. It was desirable to have groupings of hospitals in natural hospital areas, and to make available to all hospitals the resources, financial and other, which they needed. With social security provisions it was inevitable that the bulk of hospital income should be derived from central and State sources. They agreed with Mr. Bevan that hospital development must no longer be at the caprice of charity, and that it was a State responsibility that a complete and efficient hospital service should be available to every member of the community. The Bill proposed to set up a regional organization covering natural hospital areas, and including council and voluntary hospitals alike. That was something for which the medical profession had been pressing for years—that hospitals should be organized over wide areas, unrelated to the antiquated boundaries of local government. By virtue of the power of the purse, of being the source of the great bulk of hospital income in the future, the Government would be possessed of an enormous influence—of all it needed—in the planning and development of the hospital service. But the Minister proposed also to become the owner of every hospital in the country.

"Is it necessary and desirable, that position having been reached, that the State should become the physical owner of every hospital? A hospital is something more than a place in which expert work is done. It is a living entity, a centre of local loyalty and affection. The essence of a good hospital service is that there should be local interest in it and responsibility for it. Will that continue if the State becomes the physical owner of the hospital? That is an issue for us all to ponder. Will the conversion of every institution into a State establishment improve the quality of the hospital service? Will the L.C.C. hospitals—a brilliant example of local authority development—be better hospitals if the responsibility for them is transferred across the river to Whitehall? Is there sufficient evidence of the wisdom, humanity, and capacity of the State to justify the abolition of the local character and ownership of hospitals? Is this gamble one which in the public interest we are justified in taking? The endowments of voluntary hospitals other than teaching hospitals will pass, via the Minister, to the region. Local hospitals, other than the teaching hospitals, will not be permitted to accept or hold endowments. It will be no longer more blessed to give than to receive."

Further, the Minister will have power compulsorily to acquire any non-State hospitals or nursing homes that exist or may be established. This will mean a State monopoly of hospitals, free

from comparison with non-State hospitals. These things are neither necessary nor desirable.

General Practitioner Proposals

Turning to the general practitioner proposals, Dr. Hill asked what should be the basic principles of a family doctor service. Was it essential to a good service that the individual citizen should have the right to choose and change his doctor? The view of the medical profession generally, and, he believed, the public, was that this was essential. There were those who pointed out that free choice of doctor was not always available, and some who said that the public was incompetent to evaluate the individual doctor, judging a doctor by the number rather than the meaning of the letters after his name, or by social and sartorial considerations. But the individual citizen was better able to judge the value of the individual doctor in an essentially human relationship than an official or committee in a town or county hall. It was necessary with this personal service that the obligation of the doctor should be to his patient, and not divided between the patient and some employing body.

After outlining the proposals of the Bill concerning appointment to areas, payment in part by salary, and creation of health centres, Dr. Hill took up the statement of Mr. Greenwood, in the Second Reading debate, concerning a housing estate for 34,000 people near Bristol, with no doctor—a situation which Mr. Greenwood had compared with Taunton, a town of 40,000 people, with 56 doctors. It was always necessary to look into the facts of a situation before accepting a statement at its face value. Doctors had endeavoured to find houses on that housing estate, and had been told by the Bristol authorities that no houses large enough for conducting medical practice were available. There were actually nine doctors within a mile of the estate, four of them with branch surgeries within the estate itself. As for Taunton, its doctors went far and wide into the rural parts of Somerset and other counties. So much for that illustration of "maldistribution."

Under the new arrangements would have to obtain special permission to follow their fathers in practice. Where there was more than one applicant for a vacancy the central committee would decide which should go. It would decide, for example, whether to a particular area a man or a woman practitioner should be sent. It would decide who should join a group or partnership. The contention of the profession was that such errors of distribution as existed would, with a 100% service and payment in respect of every member of the community, be largely evened out. In areas of particular difficulty, including rural areas, the terms and conditions of service could be so adjusted as to attract doctors. The Minister had the power in an area which remained persistently under-doctored to select, appoint, and pay a doctor.

"We want to avoid the situation that a man or woman, after years of arduous study, and after being recognized as a fit and proper person to practise medicine, finds himself or herself debarred from the area of choice. Mr. Bevan has described the procedure as 'negative control,' which does not seem very different to some of us from direction; by closing certain areas to doctors they will be forced into other areas."

The Finance of it All

It had been said that the sale and purchase of practices was equivalent to the sale and purchase of patients. That was not true. Even though a practice changed hands as between two practitioners there was nothing to compel the individual patient to transfer to the incoming doctor. The Government argument was that in order to secure a better distribution of doctors the abolition of the capital value of practices was necessary. There was no need for this change. If goodwill was abolished, clearly compensation should be paid. But why should £66,000,000 of public money be spent to destroy this form of ownership, unless, indeed, it was felt that this was what stood between the independent doctor and his conversion into a branch of Government service? As for salary, the Minister told the Negotiating Committee in writing that a substantial proportion of the doctor's remuneration would be by basic salary; in the House he said a small proportion. It was to be hoped that the Minister was in process of modifying his view on this important issue. The profession believed that the general practitioner's success should depend on the number of

persons who chose him, and that according to that number he should be rewarded.

It was a pity that the health centre had become the focus of so much controversy. The idea was first put forward by the medical profession. It was an interesting and useful notion, worth trying out in the circumstances of different areas. But it was foolish to pretend that by the use of the mystic words "health centre" an effective contribution had been made to the country's health services. The health centre had disadvantages as well as advantages, including loss of privacy. There was always danger that the organization would submerge the individual, that there would be such efficiency in administration as to plan out of existence the human and personal factor in the doctor-patient relationship. The health centre might degenerate into the bad out-patient department at its worst. But let there be widespread experiment. The health centres now proposed were in essence aggregations of doctors' surgeries, not special diagnostic centres to bring to the elbow of the family doctor the facilities of which he stood in need.

Sum Total

What did these proposals in the field of general practice add up to? The conversion of the medical profession sooner or later into a whole-time salaried service under the State? In the public interest the great majority of the profession were opposed to conversion into a technical branch of the Civil Service. (Applause.) Did these proposals point in such a direction? What is the evidence? The Minister, in the Second Reading debate, said that the profession was not ripe for a whole-time salaried service. "There is all the difference in the world between plucking fruit when it is ripe and plucking it when it is green," he said. The remark reminded one of *As You Like It*:

"And so, from hour to hour, we ripe and ripe,
And then, from hour to hour, we rot and rot;
And thereby hangs a tale."

It was the "tale" they were anxious to discover. Mr Greenwood, in reply to an Opposition question, said that he adhered to the Labour Party policy (a whole-time State salaried service) put forward in 1943. What was the Government's policy? The country was entitled to know. The Parliamentary Secretary of the Ministry of Health has placed beyond all doubt what the policy of the Labour Party meant by free choice of doctor. He had said in the debate that "a full-salaried service is inconsistent with free choice of doctor." But the Government seemed "to be committed to both."

Finally a reference should be made to the wide powers given to the Minister under this Bill. Out of 74 clauses 29 empowered the Minister to make the regulations which were the flesh of the scheme, the Act being no more than its skeleton, and most of the regulations became law from the moment they were laid on the table of the House, needing Parliamentary action to annul them.

Dr Hill said in conclusion

"The medical profession approves the objective of this Bill. It is entitled to be heard, considered, and consulted in the working out of the scheme, for without its co-operation no effective scheme can be framed. It is itself committed to the extension and improvement of health services. It has been pressing for these for many years, long before politicians of any party thought that the health service was a subject to be tackled. It welcomes, too, the conciliatory way in which Mr Bevan put forward his proposals, especially remembering the temptation he must have been under to use that ironic and invective of which he is a master. We hope that in the Committee stage he will make such changes as will secure, within the general objective, the essential freedoms—for the patient, for the doctor, for the local hospital—for which we ask, and so gain support of the medical profession."

"The resources and organization of the State are necessary for medicine. There must be no economic barriers between the people and the medical services. But are we, in such planning, to evolve a form of service which will convert the independent doctor into a servant of the State, replacing his responsibility to the patient by responsibility to some superior body? The dilemma is whether within State organization there can be maintained not only the freedom of the public, but freedom, intellectual and other, for the doctor, freedom for his professional capacity and experience to develop. Does our experience lead us to believe that the State as we know it to-day is so wise, so omniscient, so providential a

depository of human wisdom as to justify the handing over to it in their entirety the hospital and personal health services of this country?

"My experience of our Civil Service is that it is headed by men of great ability and incorruptible integrity, but with sometimes just a slight lack of elasticity. (Laughter.) Is there not a real danger of a service so personal being submerged by administrative regulation and control? There is enough to make us hesitate whether the public interest of a better health service will be served if an independent profession is converted into a technical branch of government. That is the issue which confronts us at present."

The Turn of the Audience

The opportunity for questions was eagerly taken and sometimes, owing to the peculiarity of the auditorium, two or three questions were being asked at once. The first question was "What are the plans of the B.M.A. for the better direction of practitioners?" Dr Hill replied that the Association had no plans for direction, but only for a better distribution. Where there was inequality of distribution it was largely due to the poverty of areas or to thinness of population. In unattractive areas, urban or rural, the Minister by adapting the terms of service could attract into such localities the needed practitioners. If there still remained undoctored areas he could directly appoint practitioners. Indeed, the right to make such appointments had existed for thirty years under N.H.I., and had only once been exercised. What we do not believe to be right is that in every case of a practitioner seeking to settle in an area he should be required to obtain permission of a Whitehall committee."

Asked whether the results of the General Election did not show that the people wanted this measure, Dr Hill said that it was for the people to determine whether in voting for this Government they explicitly committed themselves to these proposals. In the election manifesto of the Labour Party *Let Us Face the Future* no reference was made to a whole-time salaried service under the State for general practitioners, nor to the conversion of hospitals into State establishments, though to be quite fair the statement of Labour Party policy issued in 1943 was clear-cut on this issue. But even if they voted Labour at the election they had as citizens every right critically to examine these proposals.

"If we agree with Dr Hill how are we ordinary people to do anything about it?" Dr Hill replied that, clearly, the Parliamentary situation was a commanding one. At the same time there were indications that Mr. Bevan did not desire or intend the extreme courses which some of his supporters would have him pursue. The individual citizen should study the proposals, make up his mind for himself, talk about them to his friends, and write to his member of Parliament expressing his considered view.

In reply to another question Dr. Hill pointed out the curious reference to research in these proposals. The money spent by the State on medical research at present was one tenth of 1% of the cost of human disease. Another questioner asked whether Dr. Hill or the President of the B.M.A. was speaking the Association's mind, as, according to a press report, the President had expressed himself as welcoming the Bill. Dr. Hill said that he presumed the questioner was referring to a report in the *Daily Express*—a brief report of 10 or 12 lines of a statement said to have been made by the President. It was an abbreviated report, inevitable in the small newspapers of to-day. "A similarly abbreviated press report of what I have said to-day might put me in the same position. I am an officer of the British Medical Association," Dr. Hill continued, "a democratic body, which of aims and represents the views of the great majority of the medical profession, and my job, which I gladly undertake, is to express the views of that body."

On a final question about the hospital position Dr. Hill said that he thought their aim should be, not to try to save the voluntary hospitals as such by a crusade, but to see to it that the State exercised its powers of co-ordination in such a way that the individual character of these hospitals was maintained. "Do not by one sweeping blow convert them into State hospitals without making it certain in your own mind that it will be for the public good." There was a danger that under a State system people of original mind—those temperamental, untidy, unpunctual people—who had contributed so much to medical know-

edge and so to human welfare would find it too difficult, of would be judged by others as too difficult, to remain in the service. Yet it was important to keep these people, and not just to have in the future a profession of people who might think it better to lie low, to pass the buck, to think of superannuation.

Sir Alfred Webb-Johnson, in thanking Dr. Hill for a magnificent speech, referred to the great achievements of Anglo-Saxon medicine—the development of anaesthesia and the working out of antiseptics in an earlier generation, the discovery of insulin nearer our own time, and of penicillin to-day—and asked whether it was likely that the medical profession would come to the people of this country with cheap and tawdry considerations or considerations of self-interest. What they were anxious to ensure was the continuance of that atmosphere of freedom which had produced these and innumerable other achievements. Although he was the son of a general practitioner, he had been divorced from general practice for nearly fifty years, but he had never been more proud of his colleagues engaged in general practice than he was to-day. They had before them the lure of the £66,000,000 for compensation, they had the assurance of State employment with good remuneration and the promise of pension on retirement; yet they had turned from all these things, rejecting the temptation, and valuing their freedom before them all. That made him proud of the men in general practice, and he thought the British public should be proud of them too.

On the following day, May 6, Dr. Hill addressed his twelfth public meeting since the publication of the Bill, attended by more than 2,000 people in the City Hall, Newcastle. He is speaking at Colchester on Thursday, May 9, and later in the month at Hastings, Chester, and Glasgow.

Correspondence

The Health Service Bill

SIR.—In the important leading article entitled "The Press, the Minister, and the Bill" (April 20, p. 612) two points appear to be open to criticism.

1. "The advances of medicine . . . are not in the clinical field but in the laboratory." This may be generally true, but what of the clinical researches of Jenner, Budd, James Mackenzie, and others like them? Further, when the advance has been made in the laboratory its value has to be tested by the clinician to ensure that apparent success is really consequential, not merely accidental. Here is opportunity for the general practitioner and his colleagues, either in the consulting-room, the patient's home, or the hospital associated with the health centre.

2. "The general practitioner does not so much want consultation with another practitioner . . . as with the . . . expert . . ." Though this statement is correct it disregards the value of consultation with fellow general practitioners, a practice probably restricted by the apprehension of a competition that would not exist in a health centre. Many doctors must at times have found these consultations quite as helpful as, if not more so than, the formal meeting with a specialist, and for the benefit of the patient and the convenience of the doctor.

None will dispute that "the incentive to excel professionally needs an atmosphere of freedom." Does not the vocation of medicine not only demand but help to produce its own freedom? This, of course, is only made possible if there is enough time available for deliberation, for discussion, for observation of facts and events, for always in every case and every treatment to ask why. Twenty-five years ago the national medical service proposed conveyed no suggestion of any want of freedom, but need for financial reform forced medical reform into cold storage, until a few years ago these two reforms changed places. Unfortunately there is now a fear that the freedom needed for the useful development of medical reform may have been frozen so long that its life is in danger.—I am, etc.,

Westbury, Wills

CHARLES E. S. FLEMMING.

SIR.—The quality of work of the able doctor of probity will not vary whether payment be by patient, by public authority, or not at all. In raising this issue in your pages Dr.

Winifred Coppard (April 20, p. 622) has perpetuated much of the confusion of thought and false distinctions that are all too commonly displayed in the lay press. The only disadvantage of a State service for this kind of doctor will be the added difficulties and frustrations that arise from regulations designed for the less able and the less incorruptible doctor. Less able but still incorruptible doctors also will present no problem; they will automatically recognize their difficulties and, free from rancour and envy, will engage in more technical branches of the profession, or perhaps take up some other work.

Doctors are not, however, confined to these two categories. Able ones, as well as the less able, exist both of whom may be corruptible. Of these, the able ones will be few. On the face of it, medicine provides, for the able, freedom from financial stringency but very considerable difficulties in the way of achieving wealth. That able minds, in significant numbers, should choose the medical profession for the purpose of making money easily and quickly is inconceivable. By definition they are not so stupid. Once in it, perhaps through the choice of a parent, it is, of course, always possible that money may become the major concern. In private practice the temptation is then to indulge patients who make frivolous demands or to conceal unpalatable truths that might, if revealed, lead to the loss of a lucrative patient. Such men will not be saved by a salaried service where the patient's good will has no cash value. On the contrary, the patients will loose their one hold on the doctor's attention, while the doctor's main stream of energies will be diverted to obtaining the favour of superiors, whence rapid promotion and the higher salary rates may be expected. In general practice this good but corruptible doctor may be flashy, urbane, and hypocritical, but at present he does no great harm and sooner or later he is left with what he desires—the wealthy and comfortable patients. When, however, this same man becomes the clever but corruptible official, he is a menace to the service of which he is a member and to all who work under him.

Lastly there are the bad and corruptible doctors. By implication the enthusiasts for a State service seem to believe that a salary will make them good in both respects. No one, I imagine, would defend this contention seriously. At present in private practice the bad and corruptible doctor is continually having his harmfulness limited by patients who go to other practitioners. But once in a public authority service, there is no known means, other than by promotion, of depriving a man of his position unless he commits some serious offence. A policy of safety first and a diligent study of rules and regulations may save him from doing much positive harm, but the public will suffer from his incompetence, his colleagues will suffer from his jealousy and spleen, and the service will suffer from his inadequacy. Nothing can make him any better, but the security of his job and the knowledge of his deficiencies will discourage him from entering alternative employment. A State salaried service cannot make a bad doctor into a good doctor, or a corruptible man into an incorruptible one. It can substitute money-plus-power for money as an incentive for the corruptible; it may hinder and frustrate the good and incorruptible. It can never transform the bad and corruptible, but it can cherish and protect these from the consequences of unpopularity with their patients.

For persons of good will, especially when they are expressing indignation, it is fatally easy to attribute to those who disagree with them the basest of motives, not seeing in that very tendency the disguised (emotional) thinking of popular oratory and the popular press. Dr. Coppard, with the best of intentions, has not, I believe, realized the artifices of her own technique. It is urgently needed at this time that we should see through such artifices and cease fruitless maligning of each other. The truth is, there are good and bad doctors, good and bad men and women, inside and outside the salaried services. But while there are already salaried services open to all who prefer them, those who find such conditions inimical to their work are not for that reason greedy or corrupt. The basic question is whether the abolition of a system by which the patient himself is the final arbiter of his health problem is likely to favour either the health and welfare of the patient or the efficiency of the doctor.—I am, etc.,

London, W.1.

H. C. SCOTT.

SIR,—I would beg a brief space to make a few remarks about the Bill. First, since we are certain of a State medical service let it be all, whether we like the idea or not, throw in our lot for the advancement of medicine and the betterment of the health of the nation.

Secondly, it is fitting that practitioners should be free to remain outside the new service and continue private practice for that small number of patients who wish to refuse the services offered to them. But for those doctors who elect to participate in the scheme there should, I feel, be no private practice at all provided the salary, whether fixed or on a capitation basis, is sufficient to meet the reasonable expectations of practitioners. From my limited experience of general practice I have been led to believe that people think that panel are not treated so well as private patients, though the same doctor is consulted in each instance. Whether it is a definite policy of doctors to slight the panel or not I cannot say, but the fact remains that many patients believe that the panel treatment and medicines are much inferior to those given by the doctor in a private capacity. Consequently, if under the National Health Service doctors are allowed to practise in a dual capacity many people will, I fear, be misguided enough to consult their doctor, or another doctor, "privately" when they think their illness is serious, fully believing that they cannot be treated efficiently under the National Health Service.

Thirdly, I fully agree with Dr. Cobban (April 27, p. 659) that a full-time salaried service will not destroy initiative. On the contrary, if the financial aspect is taken out of general practice, especially if my previous suggestion is adopted, one would have more time to devote to one's patients. This latter happy state will be reached only when sufficient doctors will have been trained to cope with the additional work of the expanded health services.—I am, etc.,

Medical School, King's College,
Newcastle-upon-Tyne.

J. STANLEY ELWOOD.

SIR,—In considering the National Health Service Bill several salient points must be borne in mind. Firstly, that the measure is as totalitarian as any ever conceived in Nazi Germany; and, secondly, that any policy of "appeasement" or procrastination will inevitably fail as it has done in the past when dealing with dictatorship, whether in Germany, Russia, or England.

The issue is clearly before each one of us in the medical profession. We must be united and make our stand now, before the Bill becomes law. We must use all our strength and our resources not to modify the Bill but to kill it.—I am, etc.,

London, N.W.10

R. M. AYTON-ORMSTON.

The Bill and the Way Out

SIR,—On a solution of the deadlock created by the Bill now before us rest the health of the nation and the hopes of our profession. The "way out" for both the parties concerned is to acknowledge their errors—the Minister his sin of commission and the profession its sin of omission.

The first mistake is that the Bill is born of party parentage—the Minister of Health and a party medical clique—whereas disease is common to all and health is coveted by all, regardless of political complexion. The Minister, being but a layman, has fatally ignored the fact that the brains and good will of the whole profession are essential in organizing our services. It is not remedied by the compensatory device of permitting private practice. This perpetuates the present evil of two types of practice and damns the Bill. People don't pay extra unless they are getting something better in return. Again, the Bill is doomed because the Minister, lacking "the goods" to give in exchange, proffers first-class service in return for the citizen's cash. The situation is ripe for a major social disaster—dispute for his party and the degradation of a noble profession.

But what has the profession done? Hard work, yes; but no reorganization to meet the need of our time. We tried to plan before, and again early in the war, but, to our shame, the effort ended like a dismal six-months' abortion. Our fault lies in offering nothing constructive in place of the Bill. Whereas the Minister's part is to provide the public with the medical service, the organization of our profession needs the technical knowledge of a highly complex science and subtle art and is

outside the province of a layman. "The man who pays the piper calls the tune," but the patron of music does not presume to dictate the composition and disposition of the orchestra.

How can Mr. Bevan redeem the situation? By pronouncing the present premature proposals an interim measure. Let him allow free discussion and amend the Bill so that the few fine features, generally acceptable, remain—e.g., regional organization of co-ordinated hospital services and extension of N.H.I. to the whole family; while letting slide *pro tem.* revolutionary ventures like transfer of hospital ownership and prohibition of sale of practices. Now, when we can scarcely keep the engine turning over, even working 12 to 14 hours a day, is not the time to expose the medical machine to all sorts of new efforts and experiments. To plaster the hoardings with "Stop death on the roads" and raise the death rate from wrecking civilian medical service is glaring inconsistency. Let money be spent where we are sure of profit—on personnel and hospitals. Highly questionable ventures like health centres and cancer clinics might be given a five-years' trial in one or two places. Having thus allayed the fears of both public and profession, let him then turn to the doctors—the technicians—and ask them to thrash out a first-class service and submit it to him and his party medical advisers for scrutiny. On that document and with the profession behind him, he would found and present a final Bill which would earn the undying gratitude of the public and bring unfading renown on him and his party.—I am, etc.,

Bristol.

A. WILFRID ADAMS.

Approved Societies and the Bill

SIR,—There has been much correspondence from medical and lay citizens in the daily and medical press, both for and against the Health Service, but comment, favourable or otherwise, from the approved societies has been conspicuous by its absence. As they have had large control of medical benefit under National Health Insurance, one cannot help wondering what their reaction to the proposed Bill can be.—I am, etc.,

East Kilbride.

J. McLAREN.

The G.P. in Consultation

SIR,—There is one paragraph in your admirable leader entitled "The Press, the Minister and the Bill" (April 20), with which I cannot agree. This paragraph states that the general practitioner does not so much want consultation with another practitioner in a health centre as with the man who has expert knowledge he does not possess himself.

Now that the old-time general consultant has been gradually eliminated from professional life, it is left to the general practitioner to hold the last remaining stronghold of clinical medicine and surgery. In the view you express, and to which I refer, this last stronghold would soon fall. The whole trend of modern medicine is to pass the complaints of each and every patient through a series of water-tight compartments of mechanical and laboratory investigation, the while diagnoses and treatment are postponed for an assessment of the findings. These of themselves are seldom convincing or satisfying, least of all to a general practitioner. And I would submit that there is to-day a plea for the preservation of pure clinical status in medicine which is as strong as any plea for so-called professional liberty.

In war, in spite of all modern devices and aids to destruction, it is on man-power alone that final victory and ultimate peace depend. So, too, in disease it is on man-power expressed in terms of clinical knowledge and experience that the patient's progress and ultimate physical and mental state largely if not entirely depend.

As I see it one of the greatest advantages in the proposed scheme for a new health service is the opportunity it affords for general practitioners to collaborate closely not only with experts and their attendant facilities, but also—equally if not more important—with their fellow practitioners. Would you segregate individual members of the profession still further?

While I am on the subject of a National Health Service, might I suggest that the public be asked to consider the implications arising for them out of the following fact: There are some

patients a doctor would rather attend for nothing than others at a guinea a time.—I am, etc.,

New Buckenham, Norfolk.

R. G. BLAIR.

**** We would certainly not advocate further segregation. On the contrary, we suggest that the general practitioner needs easier and quicker access to laboratory and hospital, and much closer contact with men having knowledge and experience in technical and special subjects —ED., B.M.J.**

Resistant Anaemia

SIR,—In reply to Squad. Ldr. A. G. Rickards's criticisms (April 27, p. 662) of our recent article:

1. The word "resistant" was used as a heading only, and not as a term of classification as he suggests. The subheading and first paragraph made it quite clear that the word was chosen to draw attention of readers to a common confusion of diagnosis, with consequent failure of liver therapy.

2. We are still of opinion that ulcers of the legs, such as we described, in association with anaemia, place the diagnosis of familial acholuric jaundice beyond doubt. The absence of any other local disease, such as venous varicosity, is, of course, assumed. If Squad. Ldr. Rickards can publish details of the one exception to this rule he has seen we hope he will do so, for the case would be of general interest.

3. He is under the "impression" that the colour index in acholuric jaundice is usually about or below unity. We stated that "the colour index is around unity or even above it. Less commonly . . . well above unity." In point of fact, in one case it was 0.9, in four it was 1, and in four it was above unity. Our emphasis was laid on the association of a relatively, or absolutely, high colour index with a small mean cell diameter.

4. We agree that the use of initials in place of names of diseases is, in normal circumstances, undesirable. We must point out, however, that in an article embodying repeated comparison between two diseases the frequent reiteration of the full names in each paragraph is wearisome to the reader. This fact weighed less with us than our deference to the demand of medical editors for the utmost brevity consistent with clarity. For this the squadron leader must blame the severe paper shortage, of which he will become aware on return to civilian life.—We are, etc.,

A. H. DOUTHWAITE.
R. L. WATERFIELD.

London, W. 1.

Iritis in the Rheumatic Affections

SIR,—I have read with interest the contribution by Prof. Arnold Sorsby and Dr. A. Gormaz entitled "Iritis in the Rheumatic Affections" (April 20, p. 597).

The problem of the aetiology and treatment of uveitis faces us in approximately one out of every hundred cases attending an out-patient department of an eye hospital. An elder colleague and teacher said to me recently that he thought he knew as much about uveitis to-day as he did forty years ago. From one whose published work always has the hall-mark of careful excellence, and whose name is now rich in honour, that was an understatement, of course. Nevertheless, our progress has been little. The clinical approach seems to be insufficient. Uveitis occurs in association with a multitude of diseases. The only common factor seems to be that there is an infection going on somewhere, and that the iris and ciliary body suffer from the effects at a distance, as it were. To say that it is a manifestation of bacterial allergy does not take us much further forward, but the evidence does increase to show that the tissues of the uvea, kidney, and joint membranes are specially sensitive to bacterial products. But Bright's disease and acute rheumatism are not commonly found together so far as I know, and certainly iritis is very uncommon in acute articular rheumatism, as the authors have shown from the literature. On the other hand, there is copious experimental evidence and some clinical evidence that the eye can be sensitized to foreign protein.

If we fail then, as we often do, to find a source of infection, what can we do to desensitize the patient? We use tuberculin in certain types of chronic iridocyclitis, often empirically if the truth be told. The results are impossible to assess in terms of anything like a controlled experiment. I find that my colleagues in general medicine use tuberculin very little. Can we

do nothing to desensitize the body to the ordinary coccal infections? The fashion of vaccines seems to have died. This is not a plea to resuscitate them, but a plea for the bacteriologist and serologists to help us to make some real advance in the study of uveitis. Doerr has an attractive hypothesis for the mechanism of immunity and allergy. He suggests that the difference between the normally immune person and the immune and hypersensitive person might simply be that in the former there is plenty of circulating antibody, while in the latter, in a hypersensitive person, circulating antibody is deficient and antibody is being engaged in the tissues themselves. Is immunity as specific as sometimes it has been thought to be?

These are some of the speculations that arise on thinking of iritis, and they are quite frankly beyond the clinician to anything about. It is a long-term job for a team. It is interesting that the salicylates so long used in this disease and rheumatism seem to reduce hypersensitivity experimentally.

In the terms of their paper the authors say, "In an attempt to assess the frequency of iritis in the rheumatic infection 815 patients suffering from various forms of rheumatism were examined for evidence of active, or past, iritis. As 11 patients were seen at clinics for the treatment of rheumatic infections, or in the wards of general hospitals, slit-lamp examinations could not be carried out, and only exceptionally a mydriatic used. The eyes were inspected through a lens under focal illumination: posterior synechiae or inflammatory pigment deposit were taken as evidence of past iritis."

Prof. Sorsby says no mydriatic was used in examining 815 patients for evidence of past iritis. Is he convinced he has not missed some cases of old iritis by omitting the use of a harmless mydriatic? The most accurate statistical analysis and the most rigid application of tests of significance would vitiate if this were so.—I am, etc.,

Glasgow Royal Infirmary.

IAN S. MCGREG

Ocular Decompensation

SIR,—An article in the *British Journal of Ophthalmology* (April, p. 232) by Major E. M. G. Galton, R.A.M.C., draws attention to the change of attitude which has taken place in recent years towards the significance of refractive anomalies of accommodation, and abnormalities of balance. These conditions should no longer be regarded as errors which need necessarily be corrected for the sake of Ocular function being dynamic in nature, Major Galton suggests that we should adopt the language of the cardiologist. A patient with a refractive error develops from it a symptom which he did not have before, we should say that he has become "decompensated," thus implying that he may again become "compensated," or symptom-free; and he points out that in these cases can be treated without glasses.

Unfortunately, though the attitude of ophthalmologists to small errors may have changed, their practice towards patients has not. (By "patients with small errors" I am referring to all those whose unaided vision is adequate but who complain of headaches, tired eyes, or other symptoms brought on by particular use of the eyes.) Generally speaking, such patients are still ordered glasses if they are civilians, or are told firmly that they do not require glasses if they are in the Army. They are not offered any other form of treatment. Seeing that alternative treatment for the relief of symptoms does exist, this means that many people are still ordered glasses unnecessarily. It is not only the optician who shows an inability to refuse glasses to any patient who comes for them.

Stutterheim showed that most of these patients have a deficiency of convergence, and described an excellent technique for convergence training. Also, I personally have found that the principles of relaxation and proper use of the eyes described by the late much-maligned Dr. Bates are definitely helpful in treating these cases. By a combination of these methods, it is my experience that there are very few such patients who cannot be "compensated" for their errors (that is, made comfortable) without the use of glasses. In the *British Journal of Ophthalmology* for December, 1937, the reviewer of Stutterheim's book, *Eyestrain and Convergence*, wrote: "There is no doubt that Stutterheim has blazed a new trail in ophthalmology." It is a trail which few have followed, presumably because the treatment requires time and patience. The refraction has got to be done in any case, and, having done it, it is so much easier

order glasses than to embark on unfamiliar treatment (which old, of course, be carried out by the orthoptists)
; it not time that an enterprising eye hospital expanded its
int department for the treatment and critical study of these
es of "decompensation," to enable us to avoid the unneces-
sary and unphysiological prescribing of glasses for small
ors, by having a better alternative for the relief of symp-
ms?—I am, etc.,
London N.W. 6

RONALD KERR.

Physical Therapy in Mental Disorder

SIR,—This correspondence dealing as it does with matters of
highly controversial nature, has followed the usual course of
ch discussions but the amount of ill informed comment has
ceeded that usually found in a scientific journal. Most of the
iters have used the words "physical" and "psychological"
antitheses, and those who have dared to suggest that the two
ethods may be combined have been more or less ignored.
Dr. D. Waterfield's letter (April 27, p. 664) prompts me to
ter the controversy even at this late stage. His statement con-
rning "these fellow creatures because of the very nature of
eir malady, are the only members of the community who are
capable of voicing their grievances" is not only misleading
it is completely inaccurate. The reference can only apply
certified psychotic patients, who, in most of the modern
ental hospitals, form a very small proportion of those sub-
ected to E.C.T. In this hospital we have, for the past five
ars, been using E.C.T. on a large scale in both psychotics and
ychoneurotics and, contrary to the experience of Dr. Ian
ottowe (April 6, p. 548) we have been very impressed with
e results, which, incidentally, are not assessed with reference
the admission/discharge rate. I am sure that Dr. Waterfield
ould not seriously suggest that a chronic hypochondriac (many
f whom we have treated successfully) was incapable of voicing
is or her grievances!

It would seem, also, that Dr. C. G. Learoyd (March 30 p. 505)
labouring under a misapprehension regarding the Board of
ontrol, which, contrary to his underlying suggestions is very
ell informed concerning the use of this form of therapy in
e many hospitals under its jurisdiction. Neither Dr. Water-
eld nor Dr. Learoyd is a psychiatrist, but it is, to say the least
it, disconcerting to note the statement of Dr. I. Atkin (March
p. 328) that "anyone can quickly learn the technique of
C.T." If he means that it is easy to acquire a knowledge of
erating the machine, I am in complete agreement, but, then,
is also easy to inject epivan or pentothal into the vein of a
atient. It does not follow, however, that the technique of
arco-analysis can be quickly mastered, merely because the
anipulation of the spring calls for no great experience.

I would submit, Sir, that the technique of E.C.T. (as opposed
merely "pressing the button") requires extensive experience
uniformly good results are to be obtained. The dosage used
each case should be assessed in the light of the original
nical findings and modified according to the response pro-
uced. The correct degree of confusion required is a matter
of fine judgment, and this can be attained only after long
amiliarity with the method. Dr. Atkin's reference to the
aining of psychotherapists, taken in conjunction with his re-
marks on E.C.T., would suggest that he does not entertain the
lea of combining the two methods. I would go so far as to
ay that this is essential, for, during the recovery period, the
atient does require psychotherapy if lasting results are to be
btained.

Many correspondents have raised the spectre of fear in refer-
ence to E.C.T., and it is high time that this was laid, once and
or all. Fear is not a normal concomitant of the treatment
less this is carried out by an inexperienced person who may
ot realize all the implications, although he may be quite capable
f handling the machine with a certain degree of dexterity. It
is true to say that the more imaginative patient may suffer from
ome degree of apprehension, but, in the same individual, this
ar would undoubtedly precede almost any form of medical
reatment. The apprehension engendered by the thought of
E.C.T. is nothing compared with that found among patients in
he waiting room of a dental surgeon, but it would be ludicrous
o suggest that, because of this fear—amounting, in some cases,
o panic—dental operations should be abandoned altogether.

Such an attitude would be classed as ridiculous, yet many well-
meaning correspondents express a precisely similar sentiment
with regard to E.C.T.

In my opinion the introduction of E.C.T. is one of the greatest
advances that has been made in psychiatry during this century.
Its employment is, unfortunately, open to abuse, and this treat-
ment should not be relegated entirely to junior medical officers,
as is the case in some hospitals, but should be carried out with
discrimination by, or under the direct supervision of, those
experienced in its use—I am, etc.,

Poolemouth

W. LIDDELL MILLIGAN

SIR,—Quite a number of your correspondents do not seem
to realize that the unpleasantness of E.C.T. can be reduced to
a minimum. Premedication with scopolamine compound
abolishes apprehension and promotes sleeping off the fit, thus
obviating recollection of the actual treatment.—I am, etc.,

Truro

H. PULLAR STRECKER.

Air Disinfection by Iodine Vapour

SIR,—Your annotation on air disinfection (April 20, p. 614)
dealt with a subject of very great importance. I was particu-
larly interested in the work of Drs. Stone and Burnet, who
found that iodine vapour in weak concentration (0.1 part in
1,000,000) inactivated the virus of influenza. I made the same
discovery in a practical way thirteen years ago.

In December, 1932, I iodized the air in all the Chesterfield
Corporation buses by my method. A month later a very severe
epidemic of influenza spread over the country. About the
middle of January half the police force were off duty in this
town, about 60 hospital nurses were in bed with the complaint,
and the industrial life of the community could be carried on
only with great difficulty. But the bus employees were prac-
tically immune—only 6 away through illness out of 300.

The transport manager was so impressed by the result of this
iodine experiment that he decided to adopt the method perma-
nently. That was done and each year the iodine diffusers are
renewed. The cost, which is small, he regards as an economic
proposition. He tells me that never once in all these years
has any bus service had to be curtailed from the absence of
the necessary staff through illness. I wonder if any other bus
undertaking in the country can say that—I am, etc.,

Kenwood, Chesterfield

JAMES A. GOODFELLOW.

Prevention of Transfusion Reactions due to Rh Factors

SIR,—In his valuable article on the prevention of transfusion
reactions due to the Rh factor Dr. F. W. Gunz (April 20,
p. 601) states that there are formidable difficulties in the way
of the ideal—i.e., the Rh grouping of every potential blood recip-
ient. He states that special laboratories are necessary for such a
service as would undertake Rh grouping and the supply of Rh-
negative blood for suitable cases. I can assure him that an
ordinary laboratory such as this hospital boasts can and does
undertake such work and supplies suitable blood to a number
of hospitals and maternity homes in the area. This work is
done at a trivial expense and with but a small addition to the
work of our laboratory staff.

During the past two years nearly 4,000 Rh groupings have
been made and many Rh negative transfusions have been given,
including three to erythroblastotic babies. Our routine is as
follows:

Our transfusion service takes blood each week. ABO and Rh
tests are done of each specimen. Rh-negatives are further tested
for R'. All antenatal cases attending the hospital and those from
the municipal antenatal clinics are ABO and Rh grouped and an
entry made on the antenatal card, the blood taken for W.R.s
providing specimens. This means about 60 or 70 such groupings
weekly, but it is a simple procedure, and it takes no longer to
put up the Rh test together with the routine ABO tests using the
tube method described by Race and Taylor. Non-maternity cases
which may require transfusion can be fully grouped on admission
to the hospital and the appropriate notation made on the ward
record card. Both "O" and "A" blood is stored, and should
transfusion be required for any Rh negative patient, suitable blood is
almost always at hand and no time need be lost in emergency.

In the series investigated in this hospital no fewer than four high-
titre anti Rh₀ (D) sera have been found: the first in a soldier
transfused in France prior to admission to a local hospital; the
remainder in obstetric cases, mothers of the above mentioned

erythroblastotic babies. Each mother willingly donated 500 ml. of blood, and from this the serum, suitably diluted and absorbed with the appropriate saliva, has enabled us to continue Rh groupings and to increase our stocks of anti-Rh serum far beyond our own requirements.

The main objection to this routine Rh testing has been said to be the small amount of high-titre serum available. I cannot help feeling that this is wrong. We have in our refrigerators enough Rh serum to group many scores of antenatal and blood donor panels, and any hospital or clinic wishing to start such tests will willingly be supplied with two active sera. Routine testing can be done with either serum and the negatives checked with the other. In this way the sera can be used economically and with greater confidence.

There can be no doubt that large-scale grouping will lead to the discovery of further samples of potent serum and existing stocks will be replenished from time to time. More importantly, the sensitization of Rh-negative mothers by Rh-positive blood transfusion will be avoided and the appropriate blood for the erythroblastotic baby and the Rh-negative obstetric haemorrhage case will always be available and ready for immediate use.—I am, etc.,

R. A. ZEFLIN,
Medical Superintendent.

St. Mary's Hospital, Portsmouth.

The Incision for Appendicectomy

SIR,—May I be permitted to express my concurrence with the views of Mr. R. H. Franklin (April 13 p. 585) on the subject of the incision for appendicectomy, with one important exception. This is in regard to his hard-and-fast distinction between McBurney's and Rutherford Morison's incisions. I have found advantage in making my skin incision for a gridiron nearer to the external superior iliac spine than is conventional, and also in a direction parallel to Poupart's ligament. This incision can be readily and rapidly extended upwards and laterally by splitting the external oblique and cutting through internal oblique and transversus abdominis muscles—i.e., converted into a Rutherford Morison. In my experience this expedient is seldom necessary. Hence a patient with acute appendicitis can be given the benefits of short convalescence and minimal peritoneal scar in the majority of cases.

Thus in a series of 100 cases of acute appendicitis operated on in 1944 and 1945 I used the paramedian incision on 31 occasions and the gridiron incision on 69. In only 5 of the 69 cases did I find it necessary to extend the incision as a Rutherford Morison. It is perhaps pertinent to add that in order to avoid expanding the incision, in 2 cases the appendix was removed by retrograde dissection.—I am, etc.,

Operation for Varicose Veins

SIR,—In pursuance of the policy of pooling information about the operation of simultaneous ligation and injection of varicose veins I beg to report three items.

First, almost every patient under my care after this procedure has a temperature of 98 and 100° F. (36.7 and 37.8° C.) for two to four days afterwards. This in spite of a technique such as I would use for a cartilage, a hernia, or thyroid. I think it must be due to the extensive chemical phlebitis that follows. I regard it as a point in support of the policy of keeping patients under observation for three to four days after the operation, although they are got up for toilet purposes from the evening of the day of operation.

In the use of saturated common salt solution for injection I have had four patients who have had small areas of skin necrosis, two at the apex of Scarpa's triangle, one at the junction of the lower and middle thirds of the thigh. Another patient had an area of dead skin the size of a florin at the back of the calf after ligation and injection of the external saphenous vein. In three cases separation and healing followed uneventfully; in the fourth case the skin necrosis was noted at the end of the operation, so the skin was immediately excised and sutured with primary healing. The practical lesson from this is to spread the injection evenly throughout the length of the varicose vein traversed by the special olive-headed needle (Down Bros.), which I introduce into the vein. It is a rare complication, but it may be advisable to discontinue the use of this

fluid. I am watching the results carefully. It has always followed the retrograde injection and never when the insertion has been from the ankle upwards.

Lastly, I have to report a death in my clinic. A spinal analgesic, which was carefully given, did not work. This was supplemented by a general anaesthetic; collapse occurred during the operation, and the patient, a young man in his twenties, died in the ward half an hour later. The post-mortem showed a well-developed thymus gland. I would make two observations on this: first, that a local or general anaesthetic is the most suitable for this procedure—I do not think a spinal analgesic advisable. Secondly, the operation is a major one and will probably always carry a small mortality. Therefore we must evaluate it correctly to the profession and to the public.

I have recently heard of the report in the daily press of the inquest on a patient who died during an operation for varicose veins, due to the injection of methylated spirit instead of saturated common salt. In future I am using this solution coloured sea blue with indigo carmine to avoid such an error, while concentrated glucose is being tinted with congo red.—I am, etc.,

Hospitals for the Aged and Infirm

SIR,—Dr. Mungo Park's letter (April 6, p. 549) is a welcome plea for hospitals for the aged and sick, a subject which is so often treated as a stepchild. During the wartime years the mental hospitals have admitted a very large number of patients with senile dementia, many of them of the simple dementing type who have no real need for special psychiatric treatment. The shortage of suitable accommodation elsewhere has resulted in their being transferred to the mental hospitals, which have provided the only portal of entry through their ever-open doors, even though the overcrowding is deplorable, often being as much as 25% over the already inadequate peacetime accommodation. Much more could be done for senile cases if a constructive policy was followed in which there was a proper means of sorting, initial observation, and specialized care in institutions meant for the purpose. Most of the cases could well be nursed in converted Army camps, such as Dr. Mungo Park has suggested. There is, however, the opportunity for the use of far larger units than those of fifty beds he mentions, as this would not give adequate classification, which is just as essential among the senile states as in other kinds of hospitals.

Making an analysis of 411 fairly recently admitted elderly cases which we are at present investigating, we were able to divide them into four diagnostic groups: (1) the simple dementing, (2) the confusional, (3) affective, and (4) paranoid. We found that the affective group, which was often accessible to conclusive treatment, offered the greatest recovery and discharge rate—namely, 49%—and the death rate recruited mainly from the senile confusional states, roughly 78% of this type dying within one year of admission. Further investigation into our case material revealed that of the 411 patients 135 have been discharged, 155 died in our hospital, and the rest remained with us as chronic material. Out of these latter cases approximately 28% need psychiatric environment; the rest do not.

These figures are suggestive of two needs: (1) that there is an increased need for special psychiatric hospitals for the aged where, with proper treatment, in a number of cases rehabilitation can be achieved; (2) that there is a need, as Dr. Park suggested, for infirmaries where the simple dementing type of seniles who are in no need of special psychiatric treatment could be looked after. The consideration of these two suggestions may offer better opportunities for the treatment of the elderly patients.—We are, etc.,

Spontaneous Hypoglycaemia

SIR,—The communication by Dr. N. G. Hulbert and Mr. R. J. McNeil Love describing a case of epilepsy complicated by hypoglycaemia in the *Journal* of April 20 (p. 603) invites comment and criticism. In this communication we are not given sufficient details with regard to the "attacks," including the one which was witnessed in hospital on Sept. 7, 1942, to be

certain that these "attacks" were in fact due to hypoglycaemic crises. The descriptions of the attacks given by the patient, himself a known epileptic, were not sufficiently clear-cut to establish a diagnosis of hypoglycaemic crises, and without definite additional evidence no other diagnosis except idiopathic epilepsy and habitual hypoglycaemia could have been made. We were told in this communication that the blood sugar on the occasion of the witnessed attack was slightly higher than the basic level found on previous estimations when the patient was free from attacks, whereas it is a known fact that hypoglycaemic crises usually arise due to a sudden fall of the blood sugar below the normal basic level for the patient concerned. Thus in diabetes a sudden fall of blood sugar from a previously high level to even 110 mg. may precipitate a hypoglycaemic crisis, and occasionally normal people have been found with blood sugars fairly steady at the level of 40 to 50 mg. %, without developing unpleasant symptoms. Other clinical evidence in this case was not presented. We are not told whether intravenous glucose actually cut short an attack or whether adrenalin was ever tried for the purpose. The improvement of the patient in his twenty-four hours of post-operative life may seem to most of us problematical, and it would be a strange thing if the blood sugar of any patient failed to rise after a subtotal pancreatectomy. It is noteworthy, as the authors themselves record that the pancreas in this case was normal.

The publication of this case is useful in that it demonstrates that there are other causes of hypoglycaemia besides pancreatic adenomata, and we think that it has another value. There are fashions in medical diagnosis as well as in treatment. Spontaneous hypoglycaemia is a favourite at the moment, and it is our devout wish that, before it runs its course, there will not be too widespread an epidemic of pancreatectomy-cum-splenectomy among the general population.—We are, etc.,

Bristol Royal Infirmary

Tuberculin Therapy

SIR,—Many years ago I published in the *Journal* (Feb. 1, 1913, p. 214) experiments to show that human and bovine tuberculin produce similar effects in the human system to what they do in a culture medium—i.e., human tuberculin produces an increase in the organic acids excreted in the urine, and the bovine produces a reduction of the organic acids excreted in twenty-four hours in the urine. The patient with tuberculous adenitis upon whom the experiments were performed improved with injections of one kind and relapsed with injections of the other kind. It therefore seems to me that a great advance would be made if we could determine easily which kind of tuberculin is required in any individual case.

Whilst I am writing, may I suggest to Dr. H. C. Manning (April 20, p. 627) that "P.T.O." is *Perlsucht Tuberculin Oberstand* and "P.T.R." is *Perlsucht Tuberculin Rückstand*—the one the supernatant fluid and the other the deposit after centrifugalizing a suspension of the bovine bacilli.—I am, etc.,

ARTHUR H. GREGSON.

Stethoscope versus X Rays

SIR,—I should be grateful for space for a few words of explanation in reply to Dr. R. A. S. Cory (April 20, p. 628).

The purpose of my letter (Feb. 2, p. 182) was in no sense a condemnation of radiography as an aid to the diagnosis of pulmonary tuberculosis. It was really in the nature of a protest against the recent tendency to suggest its infallibility either positively or negatively. It is evident that Dr. Cory himself admits that absolute dependence upon radiography would be fallacious. My description of this particular case was prompted by the correspondence which had been carried on between the radiologist and the clinician as to the relative merits of their diagnostic methods. It was evident from this correspondence that radiology claimed a practical infallibility in its ability to give a positive or negative diagnosis. The point of interest in this case was that radiography failed to demonstrate a well-marked pulmonary tuberculosis. It seemed, therefore, worth calling attention to as evidence that too much reliance should not be placed upon x-ray findings, particularly if negative.

Dr. Cory's concluding sentence is not a fair summing up of my views in regard to the value of radiography in tuberculosis. I do not "ask too much" of it since I do not expect anything more of it than an item of evidence one way or the other which might assist in arriving at an accurate diagnosis. Dr. Cory states that he has "no hesitation in saying that the skiagram will reveal many more early lesions than the stethoscope will bring to light." The point of interest is that in this case it failed to do so. So, in all fairness, did the stethoscope, though it had at least aroused the gravest suspicions. It was the microscope that established the diagnosis—I am, etc.,

Deafness from Rubella in Pregnancy

SIR.—In relation to Miss Sylvia M. Martin's letter (April 13, p. 588), the following case may be of interest. A child aged 4 was submitted for psychiatric opinion, suspected of being mentally defective. She was born on Jan. 17, 1942, at full term, with cataracts on both eyes and a congenital heart lesion, and has been totally deaf from birth. Her mother suffered a sharp attack of German measles, for which she received medical attention six weeks before the child was conceived. There is no family history of deafness. There are no gross signs of mental deficiency in the child. Evidence is accumulating which indicates that there is a direct association between rubella during the early months of pregnancy and deafness and other congenital defects in the child. Is there any evidence to suggest that the virus of rubella may damage the unfertilized germ plasma?—I am, etc.

Liverpool

MUIEL BARTON HALL

Obituary

Prof. GEORGE RITCHIE THOMSON, who died in the Edinburgh Royal Infirmary, on March 14, aged 80, was consulting surgeon to the Johannesburg Hospital and formerly professor of surgery in the Witwatersrand University. He graduated M.B., Ch.B. in 1887 and then went to Glasgow, where for several years he was house surgeon and then assistant to Sir William MacEwen. He left this country to serve as a civil surgeon in the South African War, and after its conclusion remained to practise surgery in Johannesburg. During the 1914-18 war he was officer in charge of No. 1 South African General Hospital in France with the rank of lieutenant-colonel, S.A.M.C. He was attached to the South African Division and worked for some considerable time at Abbeville and was awarded the C.M.G. for his war service. He returned to South Africa in 1919 and was the first holder of the chair of surgery at the Witwatersrand University. He retired from active practice about fifteen years ago and made his home in this country in the New Forest. His elder son, Capt. K. Thomson, M.C., is a doctor in the Colonial Service in Northern Rhodesia; his younger son, Commander R. Thomson, D.S.O., R.N., was killed in the war of 1939-45. Prof. Thomson joined the B.M.A. in 1907 and was elected a member of the Witwatersrand Branch Council in 1920.

On April 19 JOHN MORELL WILLIAMS was involved in a motor-cycle accident a few miles from his parents' home. He sustained a severe head injury, from which he died some twenty-four hours later. This Easter was to have been his last holiday before settling in practice at Banbury. He was 32 years of age. The younger son of Dr. and Mrs. Morgan W. Williams, of Morriston, Swansea, he entered St. Thomas's Hospital from Cheltenham College, and qualified M.R.C.S., L.R.C.P. in 1940. After a house appointment at Doncaster Royal Infirmary he joined the R.N.V.R. He saw much service in destroyers, including hazardous convoy work on the northern route to Russia, and numerous trips through "E Boat Alley," in the no less dangerous East Coast waters. He was only recently demobilized. A correspondent writes: John was a charming, kindly, and generous boy whom everyone liked and many loved. He seemed always to extract from life the greatest measure of fun and happiness; his good nature shone around him. All that he did he did well. In his work he had balance and sympathy, and his keen sense of humour enabled him to get full value from the passing scene.

Medical Notes in Parliament

HEALTH SERVICE BILL

SECOND READING DEBATE

Mr. ANEURIN BEVAN moved the Second Reading of the National Health Service Bill in the House of Commons on April 30. The Minister's speech was fully reported in the *Journal* of May 4 (p. 690).

Mr. RICHARD LAW said the Minister had the chance of presenting proposals which would have been welcomed by every party and by every section of opinion, lay or medical. He had preferred to bring to the House proposals which were feared and distrusted by the great majority of those who would be called upon to make them effective. It was a most extraordinary thing that the Minister, who had absolutely no administrative experience of a great Government Department, and who had no great knowledge, either practical or theoretical, of the very important subject-matter with which this Bill was dealing, should have set his own intuition and judgment against all those best informed in the medical profession and in the hospital services. The British Hospital Association and the British Medical Association were opposed to the Bill, so was the British Dental Association, and the three Royal Colleges had criticized it with varying emphasis. The President of the Royal College of Physicians was quite unable to bring the Royal College to endorse his view that the Minister, in taking the hospitals into his own control and ownership, was doing a good thing. Every body of informed and expert opinion outside the House was against the Minister on one part of the Bill or another. The Minister started by talking of sectional and vested interests. It was a monstrous perversion of the ordinary usage of words to describe great, responsible professional bodies such as had been mentioned as vested or sectional interests. He was willing to support any practicable means that would produce a comprehensive and efficient health service. But the Minister could have established a better co-ordinated and far more efficient health service if he had not been determined to sweep away the voluntary hospitals; to weaken the whole structure by removing from the field of local government one of the most important and vital responsibilities of local authorities; and to impose upon the medical profession a form of discipline which was totally unsuited to the practice of medicine, which depended above all else upon individual responsibility, individual devotion, and individual sympathy.

Ownership of Hospitals

The Minister had not given any solid justification for taking over the hospitals. The present hospital service was inadequate from the point of view of a comprehensive service, was badly distributed, and some of its buildings and equipment were completely out of date. But the main reason for this was that the finance had not been available. A hospital had a life and a purpose and an identity of its own; it was not just part of an administrative machine. The regional board should be not a controlling and directing board but a planning board. Then the voluntary hospitals could continue as individual institutions with their own identity.

The Minister had not explained how the regional boards were to be manned. According to the Bill, whatever powers the Minister gave to a board or a committee, he held in reserve authority to withdraw it and concentrate the whole service on himself. It was hardly surprising that most people felt nervous of the tendencies implicit in the Bill.

General Practitioner Service

On this subject Mr. Law said that there were two important principles. The first was that the doctor's only loyalty and only responsibility should be to his patients. The second principle was that, so far as his judgment was concerned, the doctor should be responsible to nobody else but himself, and certainly he should not be responsible to the State. Running through Part IV of the Bill there was a wholesale denial of both these principles. The doctor was to be paid, in part, by the State. He was to work in premises which were owned,

staffed, and managed, if not technically by the State, by the State as represented by the local authority; and his field of work was to be defined for him by the State. Those three things added up to the beginnings of a whole-time State medical service. It was incomplete at the moment, but it was the first step, and the step that counted, towards a full-time medical service. "Will the doctor be a better doctor because he is paid a salary? I say he will be a worse doctor, because all his prospects of material advancement will depend, not on the service that he can render to his patients, but on the impression which he is able to make on his administrative superiors."

The Minister had said that the sale of practices was the sale and purchase of patients. That was humbug. When a doctor bought a practice he was not buying patients. When a doctor sold a practice he was not selling patients, he was not selling bodies; he was selling the goodwill he had earned with his patients. By forbidding the buying and selling of practices the Minister was removing one more material inducement which a doctor had to give the best service he could to his patients. The doctor, like the miner or the operative, was bound to be interested in his material conditions, in the welfare of his family, the future of his children. To deprive him, in his practice, of the inducement to improve his material position, to improve the prospects of his children, was to do harm, not to him but to his patients. It would reinforce the tendency already begun, with the payment of the decreasing capitation fee and so forth, to look for a future and remuneration, not to an increase in the value of his practice, not to the impression he made on his patient, but to his administrative superiors. This would have a very harmful effect upon the practice of medicine.

If, by a combination of threats and bribes, the Minister persuaded all the medical profession to work under him in making this Bill effective, the doctors of the future would not be as good as the doctors of to-day. The bad effects of this Bill might not be seen now or in six months' or a year's time, but they would make themselves evident in ten, fifteen, or twenty years' time. Finally, Mr. Law urged the Minister to consider very carefully the points that had been put to him by those who were interested in the hospital services and in the practitioner services.

Two Standards of Treatment

Dr. COMYNS, in a maiden speech, welcomed the Bill. His impression was that, for the most part, the adverse criticism of the medical profession was based on lack of information, or on wrong information. The leaders of the profession had failed to keep abreast of public opinion. The average doctor wanted to do first-class work himself, and not to be just a clerk filling out certificates, or acting as a sorting office for different diseases and illnesses, and having to dispatch his patients to one hospital or another for treatment. He required a decent income and a reasonable amount of leisure. He wanted to work with his colleagues, without the fear at the back of his mind that some part of his practice might be filched from him. Not only the doctor but the public at large would benefit enormously from the Bill. Many doctors were working under the most unsatisfactory conditions both in rural and in urban areas. If health centres were equipped and staffed as they should be, they would offer a tremendous incentive and encouragement to all who worked in them to give of their best.

Dr. Comyns deprecated the fact that it would still be possible for a particular doctor to give two standards of treatment, one within and the other outside the service. When everyone was entitled to free service, it was difficult to see why anyone should want to go to a doctor outside the public service unless he expected a better standard of service than that which the doctor usually gave to his public service patients.

Viscountess DAVIDSON said that doctors were deeply apprehensive, viewing the Bill not from any selfish motive but in the light of how it would affect their individual patients. Many younger men coming into the profession would welcome the Bill because it offered a certain degree of security. They did not know what freedom of action they might be losing, because they were inexperienced. The brilliant men would go abroad to find freedom from interference and scope for their abilities. The family doctor would be replaced by the clinic doctor, and there would be no freedom of choice. The personal and the individual touch would be lost. The Minister seemed

to be determined to prevent doctors from rising to great heights in their profession. He was levelling down standards, and not lifting them up. British medicine had always been in advance of medicine in other countries, but the result of this "most backward plan" would be that it would lose its position and its prestige in the eyes of the world. In her view the Bill was another link in the chain binding us all to the machine of State. It deprived the individual of yet more of his long-fought-for freedom.

Maternity Services

Dr CLITHEROW said that the Bill would give the doctor the opportunity of realizing his ideals while he still had them. Salaries were wanted by many doctors, more especially the younger ones who, quite often, had no connexion with the British Medical Association. The possibility of everyday consultations between general practitioners depended upon the removal of the competition for patients. With salaries as the main basis of remuneration this could easily be achieved.

He asked the Minister if it was his intention to continue with the existing Central Panel Conference, or with any other similar body? Would the Minister consider making such a body a statutory one and specify its constitution, so preventing it from being manipulated by its present parent body, the British Medical Association and presenting the views of the dominant specialist opinion in that body?

The Bill ensured that hospital-booked cases would have antenatal treatment by the obstetrical team responsible for the confinement. Co-ordination of the full maternity service was in the best interests of mother and child. This kind of teamwork kept down maternal and infantile rates. The growing practice of having clinics associated with hospitals was likely to be disrupted if the emphasis was to be on health centre and domiciliary treatment for midwifery under the control of the local authority. The best service for the mother and child was at the hospital level with a co-ordination not possible under the dual system. For maternity purposes the whole service should be continued by a single body. Some means must be found to co-ordinate and not separate the maternity services.

Dr. Clitherow then went on to discuss Clause 32 of the Bill.

"In Clause 32, covering the various practitioners' committees, the Bill states that the Minister 'may recognize' these committees. Could we have an assurance that, where these committees are formed according to the requirements of the Bill, the Minister 'shall' recognize them, and thus do away with the feeling of ambiguity that these apparently permissive words cause in the mind of the layman? I am sure that the medical profession as a whole views with the greatest distaste the making of a special crime, with special and extremely heavy penalties, for the medical man who sells his practice. It is recognized that some steps must be taken to prevent such an offence, but I think that if it is left to the courts to decide whether there has in fact been any attempt to sell a practice, it will be better received by the profession than if it is left to a certificate of the Minister, even though the Bill provides that no prosecution will be undertaken without the consent of the Attorney-General."

Finally he asked for an assurance about Clause 47, which stated that any dispute under the Bill or regulations would be decided by the Minister or a person appointed by him. Was there any right of appeal to the courts, should any person find himself aggrieved by such a decision? Would the Minister give an assurance that the courts would always be available as a last appeal?

Commander MATLAND brought forward a petition signed by over 10,000 people.

"We, the signatories of this petition, having learned that the Government have tabled a Bill which involves the transfer to the State of the buildings, equipment, and invested funds of the several cottage hospitals, urge you to oppose such a measure by every means in your power. We desire that our hospitals shall be allowed to play their part in any scheme for a national health service which does not entirely deprive the hospitals of their local management and local interests."

He suggested that hospital management committees should have individual representation of the various hospitals in their group.

Mr. SARGOOD, in a maiden speech, said that London had twelve medical schools, and he asked the Minister, before finally deciding on the form of a regional board applicable to London, to give it very careful consideration and take into consultation

representatives of the London municipalities. He deplored the continuance of private mental institutions run for private profit. He asked the Minister to consider the setting up of some organization for the bulk purchasing of supplies for the hospital services. The Minister should also try to find a better way of dealing with the safeguarding of the liberty of the subject than by continuing the Board of Control.

Rheumatism

Mr YORK said the Bill did not contain one word about rheumatism, a disease which had a more devastating effect on the industrial and home life of this country than any other. One-seventh of the industrial incapacity in this country was caused by rheumatism. In the spa towns and their doctors were concentrated all the best equipment, knowledge, and facilities for the treatment of rheumatism. The Minister of Health should press on with the work of the advisory committee which his predecessor set up to advise him on rheumatic diseases and their treatment, and should see that the local interest in the spa towns was not wasted and dissipated in his centralizing scheme.

Miss BACON said her experience among ordinary men and women showed that the Minister had overwhelming support for the Bill. The defects were matters of detail. The Bill gave to thousands of people freedom which they had never before enjoyed—to consult a doctor or specialist without thinking of the cost. Most local authorities agreed that it was impossible to organize efficiently a local authority hospital service, which would require joint boards. It was ridiculous for voluntary hospitals to say that since the cost of the hospital services would be defrayed by the Exchequer their extent and quality would be determined by consideration of cost instead of need. Voluntary hospitals in the past had not had money for the improvements they wanted. She hoped we should now see the end of the very long wards, and the provision of small wards with only four to six beds.

There was a limit to the number of patients a doctor might have on his list under the public service, but there was no limit to the number of his private patients. This was open to abuse. If a doctor took on more patients than he could cope with it would not be the fee-paying patients who would suffer. Not only must people get the best, they must also believe they were getting the best.

Students and Teachers

SIR JOHN GRAHAM KERR, speaking of the quality of the recruits to the medical faculties, said some were attracted by the high ideal of administering to the sick, but the ordinary young student was practical, and not swayed entirely by sentiment. The great attraction was the glamour of the prizes—what seemed to them comparative wealth, and dignity, and the possibility of high honour. They were not attracted by safety first, and salaries and promotion by age, but by the great possibilities of their future. If this Bill went through in its present form a large proportion of these brilliant young men would go in for some other line—industry, for example—or, if they were keen on medicine, go over-seas.

These young men had as their teachers the leaders in surgery, medicine, and obstetrics. That was where they got their inspiration. No doubt these teachers in many cases were moved by high ideals, but they knew the practical advantage that came to them from giving their unpaid services in the wards of voluntary hospitals. They knew that these students would tend to come back to their old teachers for consultations or operations. Lister, Pasteur, Jenner were such teachers. If a Government voted into power in a period of post-war unrest and disgruntlement were to force the Bill through Parliament as it stood at present, it would be guilty of treachery to great socialists, the real socialists, who had given of their means for the succour of the poor and needy, and whose memorials were to be seen in the voluntary hospitals of the country.

Mr. A. W. J. GREENWOOD thought the Bill bore evidence of compromise between the interests of the public, local authorities, voluntary hospitals, and the medical profession, but it concentrated not on the prevention but on the cure of disease. Periodic health overhauls at Peckham Health Centre showed that only 1 man in 10 was really fit, 6 people out

of 10 had some disorder of which they were not aware, and 3 people out of 10 were definitely sick. That was a burden we could not afford to carry. The proposed health centres were to be places where the public came only when illness was fairly far advanced. The health centre should be a place to which the public would go for intellectual and physical relaxation and for the active promotion of health.

The anxieties of the voluntary hospitals were completely groundless. The human atmosphere of the voluntary hospital depended entirely upon the personality of the medical and nursing profession and was not dependent upon ownership of the hospital. Men did not go into the profession to make money but, like scientists, teachers, and lawyers, in order to serve their country and their fellow men.

The Government was given a mandate to plan the economic and social affairs of this country. We were embarking upon a period when State control would be extended to a number of spheres of social activity which some would no doubt prefer should remain sacrosanct. The Bill provided an opportunity to give practical demonstration of the beliefs his party had held for so long.

Sir RALPH GLYN deprecated any remarks that indicated that doctors thought only of cash. Doctors had a call to serve their fellow men, and there were few who put their service to their fellows second to their financial position.

He regretted that industrial medicine and care had not been brought into the Bill, and the question of mental care was long overdue. Hospitals for the incurable should be extended, such as those of religious organizations, which should be allowed to contract out of this scheme or be in a position to continue to look after these people.

Nursing was dismissed almost in a paragraph in the Bill. The shortage of nurses was due to lack of recognition. It was important that we should go on recruiting the right type of man into the medical profession. The standard in the past had been high.

More Medical Opinions

Dr. MORGAN did not consider this was his ideal Health Bill, but he liked it. It was the finest Health Bill that could possibly be introduced as a compromise under present conditions. Having heard the discussions in the B.M.A., the T.U.C., and the Socialist Medical Association he realized that the Minister had done as fine a piece of compromise health work as was possible.

He saw nothing in this Bill which would disturb the great relationship between the profession and the public and the profession and the individual patient about which some of his colleagues talked a lot. Many of the things the profession had asked for were in it—national co-ordination and control of research—everything in the Bill would depend on the Minister's regulations, which should be elastic, fluid, and workable. There had not been opportunity for the staff of some institutions to join their own trade union. The regulations should provide on both the professional and the workers' side for joint consultation and negotiating committees at all levels. There were certain hospitals—e.g., the Quakers' Hospital at York—which had special claims and should be allowed to carry on the special form of treatment which they gave. The laboratory, blood transfusion, and research services should not be entirely in the hands of the Ministry, but should include the local hospitals and the research which was done by G.P.s. Ambulance services should be run, if possible, on regional rather than on local authority lines.

Although up to the present there had been no Governmental medical service which had been a success, we could, with democratic regulations, with consultative committees, a good Minister, good administration and department, build a fine health service which would be an example to the world.

The Human Element

Mr. MESSER said that there were two types of social services. The first were mechanistic and affected people in the mass, not so much as individuals. It did not matter very much who administered those services. The second type was the human social service which affected the individual. In that type of social service education and health were important. The atmosphere of the hospital was as important as the cleverness

of the doctor. The patients themselves should be in close individual contact with those who administered. Hospitals, like schools, had individuality.

It was necessary in work of this description that the human aspect should be considered. The Minister said in effect: "I am the final arbitrator in deciding who shall man every stage of administration." The National Health Service Council would be the advisory and planning body. For the Minister to choose the people who were to advise him was right, but when we got to the lower level of the regional board, surely there was something to be said for its being a representative body. Mr. Messer asked, Why this loss of faith in the elective principle? Why should the regional body be a purely appointed body? How was the Minister to decide, from the names submitted to him, who were the best persons for the job? On the elective principle, the patient had some check on administration, whereas accountability, under the Bill, was only to the Minister and Parliament through the Minister.

The Doctor's Responsibility

Sir HENRY MORRIS-JONES said that to those who believed in nationalization this was a good Bill: nationalization of the health service at one short remove. No industry, and certainly no profession, could be improved by nationalization. The Minister had no consultation with any body interested in the measure. The House had never objected to consultations that established a fair measure of agreement.

This was not a National Health Bill at all, but might not inappropriately be called "national ill health" or "national disease service" Bill. The emphasis was on disease. This country had a very great record with regard to the prevention of illness. The death rate had been reduced from 22.7 per 1,000 in 1875 to 11.9 in 1944, the infant mortality rate from 150 per 1,000 50 years ago to 45 per 1,000 to-day, and deaths from typhus fever from 5,000 a year to 54. A large number of health services had not come under the Bill at all—the school medical service, services under the Ministry of Labour, the Home Office, the Ministry of Education, the Ministry of Pensions, and the Board of Trade. There were medical services in practically every Department of the State. Legislation could not create a good medical service. It had to be done by individuals. The Willink plan had the merit that it did satisfy the people who were to undertake the work. It was very unfortunate that the terms of service of general practitioners were not incorporated in the Bill. But what medical men were more afraid of was the loss of their freedom. The art and practice of medicine could only survive in an atmosphere of freedom. Initiative and enterprise in medicine had made a great contribution to the world. The doctor's responsibility was to his patient and not to the State. Some of the members seemed to think that the doctor had no right of his own at all. The doctor had three rights or duties: first, he must bow to the majority of this House; secondly, he had the right as an expert to give technical advice on all matters on which he was in a position to be consulted; thirdly, he had the same right as the miner, the docker, the agricultural labourer, and everyone else in the country to practise his livelihood and to protect the livelihood of his family. It was a very great mistake to think that all medical men had gone into the profession as a pure vocation like clergymen. Large numbers had gone into the profession for economic reasons. They had every right to be consulted at every stage of this Bill and not to have reflections passed on their patriotism. The Minister could have done as much for the health of this country by providing houses as by introducing this Bill. There were not the doctors to work the Bill, nor had we the hospitals.

Resuming the adjourned Debate on the Wednesday, Sir Henry Morris-Jones went on to regret that the Spens report was not available. He asked the Minister to drop the salary altogether from the terms of service, because the whole medical profession regarded the salary as placing them immediately in the position of State servants. The same basic salary would be paid to the inefficient and to the efficient, which was why the medical profession preferred the capitation system. The profession would also prefer to retain their goodwill and the right to sell their practices, rather than be given compensation. The distribution of doctors on the whole in this country was a fair one. There was direction under the Bill, both nega-

tive and positive. It was the first time that direction had been imposed under a statute of this country on any body of its people as a permanent measure. The negative direction was that no medical man or woman would be allowed, except by the consent of the committee—which would be the Minister—to remove from the place where he or she happened to be when the Act came into force.

He was afraid of the dull uniformity that ran through the whole scheme. It might very possibly become a utility scheme with a utility service under which doctors would sign and certify more and more, and be treating less and less and curing less and less. If the Minister would amend his Bill so as to do away with direction, to bring about a greater share in the administration of the Bill by the people who would have to work it, to encourage more interest in the voluntary and local hospitals, by allowing them a greater measure of control over their finances, with less central direction, and to create a general medical practitioner service, comprising a body of people who would work happily and with enthusiasm then he might be able to make this Bill workable. If he was unable or unwilling to make concessions the Bill would be unworkable.

Professional Self-government

Mr KEY, the Parliamentary Secretary to the Ministry of Health, said that the only argument advanced against the Bill seemed to be that it was right to conscript the labour and lives of men in a war against evil abroad, but it was wrong to conscript buildings and institutions in a war against disease at home. Every hospital or hospital unit was to have its own committee of management, and the members of that committee would not be black-hearted, black-hatted bureaucrats from Whitehall. They were to be appointed not by the Minister but by the regional board of the area concerned, after consultation with the local health authority, the local executive committee in charge of the practitioner service, the existing voluntary hospitals, and the senior professional staff in the hospitals themselves. The regional boards with their local management committees would enjoy a high degree of independence and autonomy within their own field. Each of the regional boards would have at its disposal an appropriate share of the present endowments of the voluntary hospitals, which were to be transferred into a central hospital endowments fund and redistributed according to the need of each region. The regional boards would be able to spend this money, or hand it over to local management committees to spend as they thought best, without any kind of detailed instruction or restrictive regulations from the centre. People appointed to the regional hospitals boards would not be there merely as representatives of local authority interests, but would be selected for their knowledge of hospital needs and hospital problems and be interested in hospital development, and not retarded all the time by considerations of a local character, particularly the incidence of local taxation. This hospital service was to be a national service available to all, and it was not going to be crippled by being made to conform to the present restricted areas of local administration, nor could its evolution wait on some as yet undetermined, reorganization of local government.

Mr KEY went on to describe the composition of the medical practices committee.

"It is to consist of a chairman, who must be a medical practitioner, and eight members, six of whom must be medical practitioners. Of those six, five or a majority of the committee must be actually actively engaged in medical practice. That is called direction. What then, in the name of conscience, would be the definition of professional self-government? Where, may I ask, is there any other service paid out of local funds or out of national funds where any thing approaching that amount of self-government exists?"

Obviously, some control of the distribution of doctors must be established. The B.M.A.'s view that "every registered medical practitioner should be entitled as a right to participate in the public service" was an impossible, impertinent claim. Neither town clerks, city engineers, school-teachers, postmen, dustmen, nor any class of public servants had such a right. The interests of the community demanded that the distribution of medical services should be organized with the claims and needs of patients and not the whims and fancies of practitioners as the guiding factor. The fundamental relationship between doctor and patient would remain what it was now. The *Lancet* had

said that the doctor-patient relationship in modern form needed improvement rather than preservation, it could never be wholly satisfactory while the doctor was not only a friend in need but also a friend in need of his patient's money.

Salary and Capitation Fee

The establishment of the new service would destroy a considerable part, if not the whole, of the value of existing practices. Difficulties of no mean dimensions will, therefore, be created for those whose participation, whose willing co-operative participation, is essential to the success of our service. We therefore think it wise, in the interests of that service, that they should be compensated for the loss they will suffer."

On the question of a salaried service Mr KEY said:

"The medical profession is not yet ripe for such a service, and some check of payment, in proportion to output, is still needed if we are to get from it the efficiency and the effectiveness which the community has a right to expect. That is not my statement. It is the statement of the Secretary of the British Medical Association who said in a letter to the *Times* on April 17 that a salaried medical service 'might tend to replace competition for patients by competition to avoid them.' Second, and more important, a full salaried service is inconsistent with the free choice of doctor to which we have agreed. A large salary cannot be paid irrespective of the work done, and the basis of fairness cannot be introduced into a wholly salaried service under existing conditions without compulsory allocation of the work—that is, distribution of patients among doctors. We regard the free choice by the patients as being the more important principle, and, therefore, we put forward a compromise. We propose the general practitioners' remuneration shall be partly basic salary and partly capitation fee. What the general range of remuneration shall be, what the proportion of salary to fee shall be, what the fee per head shall be are problems which remain to be determined. As has been said, we appointed the Spens Committee, consisting of half doctors and half laymen, to examine what the range of doctors' remuneration should be under the new conditions, and just as we agreed the composition of that committee with the profession, so, when we have their full report, we feel we shall be able to settle with the profession the range of remuneration and the component parts of that remuneration."

The responsibilities of local authorities were being strengthened and not weakened by the Bill. It would be welcomed by the poorer housewives who, in many cases, had seen the health of members of their family sacrificed and their own health undermined by care and worry because of the inability through poverty to seek the early help and advice of doctor and of nurse. The Bill would prevent much of that illness and disease which was found among the poorer people to-day and for them the day on which it became law would be a red-letter day indeed. The Bill was part of that great social programme which the people had so positively approved.

Proposed Amendment

Mr WILLINK moved to leave out from the word "That" to the end of the Question, and to add instead thereof:

"This House, while wishing to establish a comprehensive health service, declines to give a Second Reading to a Bill which prejudges the patient's right to an independent family doctor, which regards the development of the hospital services by destroying local ownership, and gravely menaces all charitable foundations by diverting to purposes other than those intended by the donors the true funds of the voluntary hospitals, and which weakens the responsibility of local authorities without planning the health services as a whole."

Mr WILLINK said that he was in total disagreement with the declared view of the Labour Party that "it is necessary that the medical profession should be organized as a national full-time salaried pensionable service." In view of the observations made by the Parliamentary Secretary on the consequences of the application of that doctrine, in destruction of freedom of choice, was it still the policy of the Labour Party? The Parliamentary Secretary to the Ministry of Food said on April 26, 1945, that her idea of the general practitioner service was that it should be clinically supervised by the local authority. The Socialist Ministers in the Coalition Government had, in the words of the White Paper, declared their adherence to this principle. "The sense of personal association which is at the heart of family doctoring must be preserved." Why had the baleful influence of the Minister of Health overthrown the judgment of those far more experienced? There was not a hint in the Labour Party's programme that they proposed to confiscate hospital endowments and destroy the voluntary

hospitals. If that was their intention, it was most dishonestly concealed; as dishonestly as the hospital policy of the London County Council was put forward at a time when they knew they had agreed to give up their hospitals altogether.

He asked, was it not a fact that when the Minister sent for the representatives of the voluntary hospitals he immediately said to them: "I am not prepared to discuss the question of the extinction of the voluntary hospital system"? If so—and the statement was made by their representatives in a letter to him and not contradicted in his private secretary's answer—it seemed a monstrous way of treating bodies which had been promised that they should continue to survive in undiminished vigour. The same attitude was adopted with the representatives of the profession and of the local authorities. Integration was essential, but had been abandoned because the Minister wanted to nationalize hospitals and dared not nationalize the local authority clinics. The Minister was therefore regionalizing what was essentially personal, and it was a bad form of regionalizing. It established a non-elective body subject to the directions of the Minister whenever he chose to give them and covering an area so large that there would have to be two further sub-delegations from it—three bodies, each of which would be able to say: "This is not my responsibility." The public would find themselves forced to submit to the administration of junior civil servants, unable to take the necessary decisions themselves and unable to get meetings of these distinguished regional boards gathered from these huge areas.

It was ridiculous to suggest, as the Minister did, that the planning of this service would be prejudiced by leaving endowments where their donors meant them to be. It was not the regional board but the hospital management committee that should be the real unit in the hospital service; it should be called a "board of governors" and not a mere "managing committee," and should be endowed with legal personality, with its own staff, both medical and nursing, with its own income, and a right to attract gifts and legacies.

Municipal Hospitals

In connexion with municipal hospitals Prof. Henry Cohen had said:

"The more progressive local authorities availed themselves of their opportunity and made such strides in the 10 years preceding the war, since when building has ceased, that there were, in many areas, public hospital services which equalled, if indeed they did not occasionally surpass, the voluntary hospitals of the area."

He also quoted Lord Moran as saying: "It is perfectly true that doctors are working perfectly happily under municipal administration under the Middlesex and Surrey County Councils, and I think that proves that there is nothing inherent in the municipal system which would make doctors discontented." There was nothing exceptional about the citizens of Middlesex or Surrey, and what was done there could be emulated elsewhere. It was only that many of the counties and county boroughs had had insufficient means. The major authorities were just as capable of running a hospital once they were told what sort of hospital it was necessary for them to run, as the regional hospital boards the Ministry was setting up.

"I turn to the proposals in Part IV of the Bill. Do these proposals give us any feeling that there will be an improvement, an enrichment, in the field of general practice? We on this side of the House are bound to remember at all times the view, not yet called back or revoked, of the Party opposite, that general practice should be a full-time salaried pensionable national service." The Parliamentary Secretary had admitted that a full-time salaried service was inconsistent with free choice of doctor, because it would be necessary in such a service to see that the same amount of work was done by doctors whether patients wanted to see them or not. With this Bill regulations could be made under which full-time salaried service could be introduced and free choice of doctor destroyed. The instrument had not been invented which could measure with any reasonable accuracy the extent of over-doctoring or under-doctoring. With the prospect of 100% service the doctors would in fact be most evenly distributed over the country. The risk of their not being evenly distributed was not sufficiently great to justify setting up this most unsatisfactory machinery with a large and most unsatisfactory addition to the criminal law and an expenditure of £66 million.

The Minister had introduced a Bill in which he could turn the general practitioners of this country into what his party still wished them to be—a full whole-time salaried pensionable service. There was no reason why the profession should become part-salaried at the moment except as a concession to Socialist doctrine.

Highway Robbery

Mr. CLEMENT DAVIES said that a great deal of nonsense had been talked about the freedom of choice of doctor and about direction. Doctors had never had as much freedom as they had now, and patients would have an even wider choice when the Bill was functioning fully and properly, and when there was a better distribution of the medical services.

Mr. UNGOED-THOMAS was concerned about the dual system whereby some would be fee-paying patients and others would come in under the general system. Freedom of choice of doctor was almost entirely an illusion—an illusion which had been fostered by the B.M.A. bureaucracy, which so largely misrepresented the interests and the views of doctors. Although it was an illusion, they could afford to pander to it, but not to the extent of bringing into this Bill the pernicious dual system.

Mr. SIDNEY MARSHALL congratulated the Minister on the very smooth manner in which he proposed what was obviously a very carefully prepared measure of highway robbery. If the Minister had considered the system which was adopted in the Education Act, in deciding the position of voluntary hospitals, he might have shown a little more mercy. He thought that the larger voluntary hospitals might have been allowed to carry on with State assistance by means of deficiency grants. He could not see that it was an advance in government to appoint selective regional boards directly under the control of the Minister, and not under the control of the elected representatives of the people.

Beginning of the End

Sir HAROLD WEBBE said that the Bill, the purpose of which was generally accepted, contained in its provisions many deplorable, reactionary, and destructive proposals. The transfer of the hospitals represented an encroachment of the first magnitude on local government, and was the most serious loss it had been called upon to sustain. Those were the words of the great Socialist London County Council, which promptly declared their complete, ready, and cheerful acceptance of the proposals. This was exactly what would happen in any dictatorship country. The local gauleiters had had their orders, and in fact the leader of the London County Council was in such a hurry to carry out his orders that he actually announced in the public press the decision of his party to support unconditionally the Minister's proposals before it was conceivably possible that any one of its members could have had even the White Paper in his possession. That was a fine example of intelligent foresight.

The Bill tore the very heart out of the whole of the local authorities' health services, and it left them emasculated, truncated, deformed, and completely open to future attacks on the autonomy of local authorities. It marked the beginning of the end, even of the major authorities. The hospitals, the whole control of medical services within the local authorities, were to be transferred to regional boards, consisting of men nominated by the Minister—his creatures—serving on sufferance and subject at any moment to direction and regulation by him. If the Bill in its present form reached the Statute Book, at that very moment the Minister would have signed the death warrant of local government as we knew it and would have made a laughing-stock of our claim to be a democratic country.

Voluntary Inbreeding

Mr. SOMERVILLE HASTINGS said that anything that would limit the far-sighted planning of the regional hospital committees, or would limit the influence of the universities and teaching schools, one of which it was proposed should be, so far as possible, situated in each region, would be a disaster. If the hospital management committees had power to appoint doctors and senior staff they were very liable to follow the voluntary hospitals into that inbreeding which had been the curse of the system. There was no reason why local interest, local patriotism, and local pride in a hospital should not be

developed and continued under a municipal or national system as much as under the present voluntary system. About pay-beds, he said that a very strong case could be made for permitting those who wish to buy privacy to pay for a single bedded ward, provided, of course, that it was not needed for a case that required it for medical reasons. If the Minister or the Parliamentary Secretary should need hospital treatment, they would be quite justified in making use of one of these pay-wards because in them they could discuss matters with their officers without the B.M.A. learning of everything that was said. Patients who paid for their treatment would believe they were getting something better, and it would be in the interests of the surgeons and physicians concerned to keep up that delusion, if indeed it was one. This was most undesirable. There should not be two sorts of wards and two sorts of treatment in the same hospital. It might be a convenience to the doctors to have all their patients, private and public, under the same roof, but surely the patients in the hospital were even more important than the doctors.

Lieut.-Col. GAGE said that the proposal to remunerate practitioners by part-salary and a tapering capitation payment was bound to produce a general levelling in the standard of remuneration paid to the general practitioner, and it was not really suitable to any profession, and least of all to the medical profession. The capitation fee alone was a fair method of rewarding the practitioner. He would have preferred to see the global sum of £56,000,000, which was to be spent on compensation of elderly practitioners, used for providing security for the young man at a time when he needed it, which was before he qualified—not after he qualified. If some of that money could have been devoted to the provision of scholarships and other aids for getting the young man through his years of study, then indeed a great deal would have been achieved. He hoped that health centres would not have the effect of removing the queues from the surgeries to the health centres and making them longer queues, because more people would be attending. He hoped, too, that the doctors would be encouraged to go into the homes of the people and would not simply use the health centres as glorified surgeries where they expected everyone to go and wait in rows.

Mr. BOARDMAN thought that Mr. Bevan had paid too high a price by the concession that a doctor who participated in the service could also take fees. A miner would not be convinced that he had the same treatment as the mineowner who could pay for it.

Lord WILLOUGHBY DE ERESBY asked whether it was the intention of the Minister to nationalize war memorials, as Rutland's hospital was also the county war memorial. He (Lord Willoughby) had spent most of last year in a Ministry of Health or a State hospital, in a voluntary hospital, and also in a Canadian Red Cross hospital. Despite much kindness in all three, he had to admit that, given a free choice, the Ministry of Health hospital would be his last choice for further treatment. The system was wrong which did not enable doctors or staff to give just that extra bit of treatment, that extra bit of comfort which were so important when one was ill for months.

Evidence of the Hospital Surveys

Dr. HADEN GUEST hoped the Minister would adhere very closely to the Bill in its present form with its two main provisions of a complete hospital service and a personal medical service for all persons of all ages, insured or uninsured, without exception. If the national health service did nothing more than provide these two things it would be of the very greatest benefit to the health of this country. Poor people who were not in the scope of the panel service would now come into the service and get treatment. Uninsured women would no longer be afraid to consult the doctor because of the bill their husbands would have to pay. And mothers would more readily take their children to the doctor for so-called minor infectious diseases like measles and whooping-cough, the complications of which were considerable.

The necessity for a hospital scheme on a national basis arose from the facts as shown in a recent series of hospital surveys. The voluntary teaching hospitals would retain their independence and their leading position—in fact, an improved position to that in which they were at present, because they would be freer from any financial anxiety.

Mr. WILLINK: "The teaching hospitals will be subject to any direction the Minister may give, the limit to this direction being in no way defined in the Bill."

Dr. GUEST replied that he had not the least fear of any domination by the Minister of Health. Things done by agreement among equals were not the subject of unnecessary fears. The survey for the London area revealed a deficiency of beds for acute medical and surgical cases, for tuberculosis, and for maternity; and very poor provision indeed for the chronic sick. The distribution of hospitals over this area was haphazard. The problem was not one of buildings but primarily of expert medical and nursing staff. During the war, in spite of inadequate numbers of specialists and doctors, we managed, by co-ordinating the work of the voluntary and municipal hospitals, to create an Emergency Medical Service which did most valuable work. It saved thousands of lives and many hundreds of doctors. There was not the slightest reason why we should not do the same kind of thing in peacetime.

Mr. WILSON HARRIS believed that the anxiety which existed centred around two main questions—the future of the family doctor and the treatment of the voluntary hospitals. But if this measure was passed the lot of the ordinary general practitioner in many respects would be easier, and in only a few respects more difficult, than it was to-day. No health centre existed as yet, and it might be some time before any appeared. But when they did there would be nothing to require any doctor to go near one. He could still see patients in his own surgery. If, however, a doctor was wise enough to use the centre he would have his own hours for consultation, his surgery hours, just as to-day. Skill was not the only quality required in a medical man. In no profession was personality rated higher or did it play a greater part. Could not individual hospitals keep their endowments, particularly as the Minister was paying the basic necessary costs of management and operation? It would be the wise and statesmanlike course to leave the endowments to the individual hospitals, and merely take their buildings and fit them into the general scheme. He (Mr. Harris) could not see why local support should not continue. It was a pity that this great measure would not have, on its Second Reading, the support of a united House.

Freedom of Certification

When the debate was resumed on May 2 Colonel STODDART-SCOTT pointed out that the Bill did not provide a comprehensive health service. There was no attempt to co-ordinate the services of seventeen Government Departments. Nor was it a health Bill. It was purely a hospital or a medical service Bill. Only in Clause 16, in six brief lines, was there any positive health provision. They had a Bill which coerced the medical profession and coerced hospitals and local authorities. He thought the Bill contravened one of the promises of the Labour Party at the Election, that if they were returned to power they would set up a Ministry of Housing to deal with housing alone. Instead, there was the Minister giving five minutes only each day to considering the health of the people and spending the rest of his time stopping people building houses. There was anxiety among the people when they found that doctors were to be employed by the State and to be responsible to some statutory body set up by the State, which took its orders from the Minister. Under the National Insurance Bill a man with two children would receive £3 2s. 6d. for an unlimited number of weeks on the certificate from a doctor, and he did not think there should be anything in this Bill which would make his doctor less independent and fearless about certification.

There was nothing immoral in buying and selling medical practices. The present Prime Minister and the present Lord Privy Seal both put their signatures to the Coalition White Paper, which intended to carry on this "immorality." The buying of practices had never been that financial burden round the neck of a young man that it had been described. A medical man, from the day he qualified, could go into a decent-sized practice, and, by paying off the purchase price over a period of 12 years, secure for himself, during the whole of that time, no less than £700 per year. The drawback to men going into medicine was the medical education. £66,000,000 of the taxpayers' money was going to be thrown away so that this bit of party politics could be introduced. It would be better used if it were spent on providing cheaper medical education.

evidence to support the claim; it ought to have asked whether there was any evidence to negative it, and the learned judge found none.

On the other hand, in considering a claim by the widow of a Capt. Bourne, the Minister had sent his reasons to the medical services division of the Ministry to ask whether it agreed, and the division sent the paper back with an endorsement "Medically agreed" signed by one of its doctors. This constituted authentication by a medical man, and therefore made the Minister's reasons evidence. The tribunal, considering it with the claimant's evidence and being advised by its medical member, decided against the claimant. The learned judge found that the tribunal had sufficient evidence for its conclusion.

ACCIDENT IN A DOCTOR'S HOUSE

A Glasgow radiologist, having advised a patient, asked him to let himself out. Some time later the patient was found lying on the basement stairs with a broken spine; he died two weeks later, and his widow and eight children were awarded £1,641 damages by the Court of Session in Edinburgh. Their Lordships found that the passage through which the patient had had to go was dark or badly lit, and that the nearness of the unlighted basement stairs constituted a danger to a person not acquainted with the house; they therefore held that the doctor had been negligent. The law of England and Scotland alike makes the owner of premises liable to take all reasonable steps to protect a person who comes on to the premises by invitation, and a patient visiting a doctor would fall into this category. The Court's judgment was, however, upset on appeal. Lord Cooper, the Lord Justice-Clerk, found on the evidence that the stair light had been lit and the door open. It could not have been foreseen that any normal person seeking to go out would turn away from the lighted portion of the premises in order to explore, unaided, the unlit portions of a strange house. The doctor had no duty to foresee the unaccountable conduct of the deceased, who was himself the author of his fatal misfortune.

The Services

Surg Vice-Adml. H. St. C. Colson, C.B.E., has been appointed an Honorary Physician to the King in succession to Surg. Vice-Adml. Sir Sheldon Dudley, K.C.B., F.R.S., who has been placed on the retired list; and Surg. Rear-Admls. F. J. D. Twigg and H. R. B. Hull have been appointed Honorary Surgeons to the King in succession to Surg. Rear-Admls. C. V. Griffiths, D.S.O., and W. H. Edgar, C.B., O.B.E., respectively, who have been placed on the retired list.

The King of Norway has conferred the Norwegian War Medal upon Temp Surg Lieut. H. H. Kennedy, R.N.V.R. for assistance given to personnel of Norwegian corvettes in difficult circumstances.

The King of the Hellenes has conferred the Greek Distinguished Service Medal upon Temp Surg Lieut.-Cmdr. V. O. B. Gartside, R.N.V.R., for services as medical officer in the Greek destroyer *Adrias*.

Major (Acting) P. A. M. Van De Linde and Capt. R. H. S. Lee, M.B.E., R.A.M.C., and Capt. S. P. Jain and Lieut. Natarajan, I.M.S., have been mentioned in dispatches in recognition of gallant and distinguished services in the field.

The following appointments and mentions in dispatches have been announced in recognition of gallant and distinguished services while prisoners of war:

O.B.E. (Military Division)—Lieut.-Cols. (Temp.) P. C. Dutta and W. J. L. Neal, I.M.S.

M.B.E. (Military Division)—Capt. J. A. Sutherland, R.A.M.C. Majors H. S. Manni, and B. L. Kapur; Major (Acting) L. W. Ashton-Rose; Capt. T. C. Bose, P. V. Ramaniiah, and B. D. P. Rao, I.M.S. Subadar C. Dev and Jemadar S. Singh, and Conductors G. E. McDonald and P. Wolfe, I.A.M.C.

Mentioned in Dispatches—Lieut.-Col. G. D. Malhoutra, O.B.E., Lieut.-Col. (Temp.) B. Chaudhuri, O.B.E., Lieut.-Col. (Acting) K. F. Alford, Majors L. Feinholz and J. O'Neill, Majors (Temp.) A. C. Glendinning, G. A. Graham, M. N. Sardana, and S. A. Hasan, Capt. B. I. Evans, A. M. Best, N. K. Mehra, N. S. Pillay, A. Strachan, B. N. Sudan, and A. K. Thomas, I.M.S. Subadar A. A. Bakhar, Jemadar (now Subadar) A. K. Chanda, Jemadars D. N. Malik, and K. Singh, Cdr. G. McG. Hartley, Sub-Cdrs. R. R. Braganza, M. V. Game, C. H. James, D. A. Plomer, J. J. G. Towers, and T. A. J. Wickham, I.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

Died—Surg Lieut. John Morell Williams, R.N.V.R.

¹ *Scotsman*, Feb. 23, 1946.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The E. G. Fearnside Scholarship for clinical research on organic diseases of the nervous system is open to members of the University or of Girton College or Newnham College who are graduates or titular graduates in Medicine, or to graduates or titular graduates in Arts who have passed Part II of the Natural Sciences Tripos. Applications must be sent to the Registry before June 24.

UNIVERSITY OF EDINBURGH

Prof. J. R. Learmonth, C.B.E., has been appointed regius professor of clinical surgery. This chair was formerly held by Sir John Fraser and has been vacant since he became Principal of Edinburgh University. Prof. Learmonth will hold the post together with his present chair of systematic surgery. It is the first occasion on which two posts have been combined in this way at Edinburgh. Prof. Learmonth graduated with honours at Glasgow University in 1921, gaining the Brunton Memorial Prize for the most distinguished graduate of medicine for the year. Following the award in 1924 of a Rockefeller Medical Fellowship he spent a year at the Mayo Clinic in the United States, and in 1928 returned to join the surgical staff of the clinic as a neurological surgeon. From 1922 to 1928 he worked as assistant to Prof. Archibald Young, first in the Anderson College of Medicine, Glasgow, and later in Glasgow University. In 1932 he succeeded Sir John Marnoch as regius professor of surgery in the University of Aberdeen, and in 1939 was appointed to the chair in Edinburgh.

SOCIETY OF APOTHECARIES OF LONDON

At a meeting of the Court of Assistants, with the Master, Dr. Hugh F. Powell, in the chair, Drs. N. S. Finzi and Macdonald Critchley were elected to the Court and took their seats. Dr. J. P. Hedley was reappointed as the Society's representative on the Central Midwives Board.

On March 12, Lord Moran, President of the Royal College of Physicians of London, delivered a lecture entitled "Into Battle" to an audience of about 150 guests. The lecture was followed by the first post-war entertainment to the Members of the Society.

A special meeting of the Court was held, under the chairmanship of the Master, in connexion with the National Health Service Bill.

The Diploma in Industrial Health, *honoris causa*, was granted to: Dr. A. J. Amor, Dr. John C. Bridge, Prof. F. A. E. Crew, F.R.S., Dr. M. Margaret Dobbie-Bateman, Dr. M. W. Goldblatt, and Dr. E. R. A. Merewether.

The Diploma of the Society was granted upon examination to the following candidates: E. T. De Mel, J. S. E. Gilbert, J. J. Maskell, M. Lakner, P. F. Osborne, A. M. Benson, R. Hodgkinson, K. R. Brookes, R. A. Armstrong, E. H. Osborn-Smith.

CONJOINT BOARD IN SCOTLAND

The following candidates, having passed the final examinations, have been granted the diploma of L.R.C.P.Ed., L.R.C.S.Ed., L.R.F.P.&S. Glas.:

Y. Anwar, H. Biggins, M. Bleicher, W. A. Brown, I. S. Bruce, A. M. Buchanan, J. Caldwell, W. Campbell, R. E. Dwork, F. Fleming, N. Katz, S. O. Krause, L. W. Kyrollos, A. McDonald, Catherine McGuigan, R. D. G. MacLennan, I. H. Mathieson, N. Meleca, Edith M. Muggoch, L. R. Orens, G. L. Park, F. R. Roberts, Caroline Y. B. Robertson, D. N. Rosenberg, J. Rusius, Agnes E. Russell, J. Singh, J. W. Tandatnick, T. G. Thomas.

Medical News

The annual general meeting of the British Association of Physical Medicine will be held at the Royal College of Surgeons, Lincoln's Inn Fields, W.C.2, on May 15, 1946, at 5.30 p.m., and will be followed by a dinner in the College.

A meeting of the Tuberculosis Association will be held at 26, Portland Place, W., on Friday, May 17, at 5 p.m., when a paper on "Primary Pleurisy with Effusion—Clinical and Epidemiological Features and After-history of 190 Cases" will be read by Dr. Brian Thompson. At 8 p.m. a discussion on "The Morbidity of Tuberculosis" will be opened by Dr. W. T. Russell and Dr. Norman England.

Dr. Philip Inwald, Dr. Horace Joules, and Dr. Stephen Taylor, M.P., will be the speakers at a meeting arranged by the Socialist Medical Association to be held at Denison House, 296, Vauxhall Bridge Road, S.W., to-day (Saturday, May 11) at 3 p.m. Mr. Somerville Hastings will preside, and the subject will be "The New National Health Service—The Profession and the Public."

In connexion with the bicentenary celebrations of the Middlesex Hospital there will be three lectures at 4.30 p.m. on May 20, 22, and 23: Sir Robert Robinson, P.R.S., on 'Chemistry and Medicine'; Sir Edward Mellanby, F.R.S., on 'The Future of the Medical Sciences'; and Sir Lionel Whitby on 'The Middlesex and Medicine'.

The first post-war reunion of the Edinburgh University Club of London will take place at the May Fair Hotel, Berkeley Street, W., on Wednesday, May 29, at 6.10 p.m., when members may meet the President-elect, the Right Hon. Sir John Anderson, and Lady Anderson. Any member not having received his invitation by May 18 should communicate with the hon. secretary, Dr Bruce Williamson, 12, Wimpole Street, London W.1.

An exhibition of British chemical research organized by Imperial Chemical Industries, will open in London in June. Its purpose is to demonstrate how, under the stimulus of war, British chemists made discoveries of permanent importance to mankind. The exhibition will be held at the Tea Centre, Lower Regent Street (corner of Jermyn Street), London, S.W.1.

The Illuminating Engineering Society has arranged a lighting exhibition on Wednesday and Thursday, May 15 and 16, as part of its session at which papers will be read on wartime applications of light and future development after the war. The programme includes an address on Wednesday at 11.15 a.m. by Prof. H. Hartbridge on light and vision. The exhibition is at the Lighting Service Bureau which adjoins the Institution of Electrical Engineers, 2, Savoy Hill, Victoria Embankment, W.C., where the sessions will be held. The office of the Illuminating Engineering Society is at 32, Victoria Street, S.W.1.

The National Association for the Prevention of Tuberculosis announces refresher courses as follows: Course for medical practitioners and tuberculosis officers at Papworth Village Settlement, June 18-20, fee two guineas for lectures and demonstrations, and two guineas for three nights' accommodation at Girtton College. A course on treatment of tuberculosis will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, Sept. 23-28, fee four guineas. A Newcas-le-upon-Tyne course will be held from Nov. 4 to 8, fee four guineas. Early application should be made to Dr. Harley Williams, Tavistock House North, Tavistock Square, London, W.C.1.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In England and Wales there was a sharp drop in the incidence of whooping-cough 327, scarlet fever 315, acute pneumonia 219, measles 160, dysentery 81, and diphtheria 48.

The returns for scarlet fever and diphtheria were the lowest for 32 weeks. The fall in scarlet fever was general throughout the country, but the decline in diphtheria was confined to three counties: Durham 17, Northumberland 15, London 14. Whooping-cough was generally less prevalent, except in London and the adjacent counties, where there was no appreciable change. Cases of measles decreased slightly in most areas, Lancashire was the only exception, with an increase of 20.

The notifications of dysentery were the lowest for the past 22 weeks. The chief returns were Lancashire 28, London 22, Surrey 16, Middlesex 15, Warwickshire 13.

In Scotland decreases were recorded in the notifications of measles 351, acute primary pneumonia 90, diphtheria 38, and whooping-cough 29. In contrast there was a rise in dysentery from 32 to 60, due to a small general increase, the only fresh outbreak was in Renfrew County and involved 10 persons.

In Eire there was a decline in the incidence of diarrhoea and enteritis 24, diphtheria 15, and scarlet fever 13.

In Northern Ireland the only change of note was an increase of 13 in the cases of scarlet fever.

Quarterly Returns for Northern Ireland

During the December quarter of 1945 a birth rate of 21.1 per 1,000 was recorded; this was 0.4 more than the average of the five preceding fourth quarters. Infant mortality was only 55 per 1,000 registered births, as against 74 for the five-years average. Maternal mortality was 2.1 per 1,000 births and was 0.9 below the average. The general death rate was 11.2, being 1.6 below the average rate for the five preceding fourth quarters. Deaths from infectious diseases included 66 from diarrhoea and enteritis under 2 years, 13 from whooping-cough, and 5 from diphtheria. Deaths from pulmonary tuberculosis were 166 and from other forms of tuberculosis 51, which totals were 38 and 14, respectively below the five-years average.

Week Ending April 27

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,054, whooping-cough 1,669, diphtheria 389, measles 2,793, acute pneumonia 654, cerebrospinal fever 48, dysentery 163, paratyphoid 5, typhoid 4.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 20.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (incl. d. g. London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases, a blank space denotes disease not notifiable or no return available.

Disease	1946					1945 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)

Deaths (0-1 year) Infant mortality rate (per 1,000 live births)	382	51	47	39	14	342	46	56	45	13
Deaths (excluding still births) Annual death rate (per 1,000 persons living)	4,588	652	570	199	136	4,466	600	621	228	115
Live births Annual rate per 1,000 persons living	7,056	997	917	413	271	6,432	674	849	394	292
Stillbirths Rate per 1,000 total births (including stillbirths)	247	34	28	—	—	196	14	26	—	—

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county) and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

§ Imported cases.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: Altholery Westcent, London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: Articulate Westcent, London.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: Medisecra Westcent, London.

B.M.A. SCOTTISH OFFICE: 7, Drumshugh Gardens, Edinburgh.

ANY QUESTIONS?

Toxicity of Mercurial Diuretics

Q.—A patient aged 50, with weakness of the right heart, developed marked oedema of both legs. An increased dose of digitalis and an injection of 1 ml. of "neptal" were given. Several hours later he became confused, collapsed, and cyanosed, with Cheyne-Stokes respiration and a pulse rate over 100. He was in a state of semi-coma for about twenty-four hours. Treatment by digitalin, oxygen, etc., resulted in improvement. At the end of a week it was decided to administer another 1 ml. of "neptal" as it was considered improbable that it would have caused this reaction. The administration, however, was followed after a short interval by a collapse similar to that previously observed. His condition continued to deteriorate, and he died the following morning. Is such a reaction common?

A.—"Neptal" is the hydroxy-mercury-propanolamide of *o*-carboxyphenoxycetic acid. Acute toxic reactions and sudden death following the injection of mercurial diuretics are well known, though they are very infrequent in relation to the large quantities of these drugs which are now used in cardiac therapeutics. Up to 1942 there had been reported a total of 26 deaths from mercurial diuretics over a period of sixteen years. Death has more commonly followed administration intravenously than intramuscularly or per rectum, but of course the intravenous route is the commonest method of administration and there is no real evidence that reactions can be avoided by giving the drug intramuscularly.

Fatal accidents are probably relatively more common in patients with nephritis than in those with heart disease. Often, in the present case, there have been reactions of some type after a previous injection of the mercurial diuretic, and these reactions should be regarded as warning signals and, as a general rule, should contraindicate further use of the drug. If mercurial diuretics must be given, then a change to another preparation is indicated. Death may nevertheless occur with the first injection, and from this it would appear that the reactions are not allergic or due to sensitization. They are the result of intolerance, or abnormal susceptibility, to the pharmacological effects of the drug.

The exact mechanism of death is probably toxic action of the mercurial diuretic on the cardiac muscle, with terminal ventricular fibrillation and syncope. In most cases death occurs within a few minutes of the injection. Where death is protracted, as in the present case, additional factors, such as digitalis-poisoning due to mobilization of the drug in the blood stream during diuresis, chloride depletion, renal impairment, and faulty excretion of the mercurial, can probably be invoked.

Eye-to-eye Ophthalmoscope

Q.—Can you give me any information about direct-vision eye-to-eye ophthalmoscopes?

A.—I remember seeing and using one of the direct eye-to-eye ophthalmoscopes in 1927. It was a flat, box-like structure and there was a rubber eye-cup at each end—one for the surgeon and the other for the patient. These cups were applied closely to the eyes to exclude light. The artificial illumination inside the box lit up the patient's fundus and a green cross inside the

box. The patient was asked to fix the green cross. The fundus was quite well seen, but the patient found it difficult to keep the fixation steady, and so the view of the fundus was constantly changing. The same difficulty was reported by other observers. I have not seen the instrument in use since, and I believe that it is now difficult to obtain.

Male and Female Homosexuality

Q.—Can you explain the apparent discrepancy in the legal attitude towards female as distinct from male homosexuality? The law seems to treat the latter with great severity, while completely ignoring the former. Is this actually correct, and, if so, why?

A.—The law imposes very heavy penalties on a male who commits sodomy, and lesser but severe penalties on males who together commit grossly indecent conduct not amounting to sodomy. It is, however, not an offence for two women to indulge in homosexual behaviour together in private (if both consent and are over 16), nor is such behaviour a matrimonial offence serving as a ground for dissolution of marriage or judicial separation, as is sodomy (but not gross indecency) in a husband. An attempt was made in the House of Lords to insert a provision in Herbert's Bill (now the Matrimonial Causes Act, 1937) making homosexual conduct by a wife a ground for divorce, but the feeling of the House was so obviously against the amendment that it was withdrawn after very little discussion.

The reason for the discrepancy in the attitude of the law towards the two sexes is a matter of speculation. Sodomy is strongly prohibited by Holy Scripture and has always been a very serious offence in the eyes of the Church and the canon law. Doubtless its connexion with ordure is one reason for this emphatic condemnation, but another reason must be that it tends to diminish the reproduction of the race. The legal prohibition of grossly indecent conduct is designed for cases where the evidence of actual sodomy is not sufficient. Homosexual relations between women are not prohibited by scripture. Another possible reason for the difference is that law has been chiefly made by men, who, though conscious of the evil of male aberrations, have not felt themselves called upon to consider similar practices in women, nor even to admit their existence. (The attitude of the House of Lords to the proposed amendment of Herbert's Bill was a queerly negative one, as though the amendment dealt with a subject that had no real existence and certainly no importance.) Again, homosexual conduct between women does not offend the sense of decency so grossly as does sodomy, and leaves no physical trace. None of these suggested reasons, however, has any traditional authority.

Electrotherapy of Cerebral Thrombosis

Q.—I recently read that hemiplegia due to cerebral thrombosis may be treated by applying a constant galvanic current to the skull over the affected side and to the cervical sympathetic on the same side, the rationale being that the constant current causes vasodilatation of the cerebral vessels. Surely stimulation of the cervical sympathetic causes vasoconstriction and section vasodilatation (JOURNAL, 1938, 2, 667). Has this treatment been tested by others?

A.—I do not know of any literature dealing with this point. The rationale of the "treatment" is far from convincing. Even if dilatation of the intracranial arteries were produced there is no certainty that the area of cerebral softening would be reduced by such a process.

Failure to Menstruate

Q.—A girl aged 16 has so far failed to menstruate. She is apparently healthy, and her breasts and external genitalia are well formed. There is no evidence of haematocolpos or haematometra. Her mother is neurotic, and the girl shows similar tendencies. Is any treatment required?

A.—Since the girl's general health is good, and particularly as the development of secondary sex characters is proceeding normally, no treatment is required to bring on menstruation. The premature application of hormone therapy in these cases is to be deprecated. No harm can result from waiting for at any rate another year.

Antenatal Care of Pauper Patients

Q.—Is a pauper doctor entitled to charge a pauper patient for antenatal examinations?

A.—No. An insurance practitioner's terms of service require him to give "all proper and necessary medical services" of a general practitioner character, excluding attendance at a confinement or attendance within fourteen days after labour for any condition resulting from the confinement. Antenatal treatment of a non-specialist character is regarded as being within an insurance practitioner's contract.

Smokers' Headache

Q.—What effects and what symptoms may be produced by the sudden withdrawal of tobacco in a man aged 37, who has been smoking an average of 30 cigarettes a day for at least twenty years? This patient consulted me for abnormal nervousness with cardiac irregularity. The radial arteries showed slight thickening with tortuosity but were soft and relaxed. The blood pressure was 104/60 mm Hg. There was no cardiac enlargement and the sounds were clear but there were frequent extrasystoles. On giving up smoking at first he felt much better and the nervousness and extrasystoles disappeared, but within a week or two he began to complain of headaches chiefly unilateral (left side) and giddiness on getting up in the morning. The blood pressure now varies between 130 and 140/80 mm Hg. He attributes the headaches to the withdrawal of tobacco since he finds relief within five minutes of smoking a cigarette though this is associated with a return of the cardiac irregularity. Is this view correct or not?

A.—There is fairly general agreement that tobacco raises the systolic and diastolic blood pressure and the pulse rate in most normal and diseased subjects. The blood vessels of the skin are constricted while those of the muscles are little if at all affected. These effects occur during smoking and persist for some little time after this. Occasional cases in which smoking has produced irregularity of the heart, disappearing after giving up the habit, have been reported. It is very unlikely that the phenomena described in this patient are due to the absence of tobacco. It seems unlikely that the rise in blood pressure has been caused by the cessation of smoking but in any case it is still well within the normal range. The occurrence of left-sided headache relieved by smoking is interesting because of the recent suggestion that migraine headache is due to dilatation of the temporal arteries, and that ergotamine tartrate relieves it by constricting these vessels. Is it possible that the headache in this instance is due to a similar mechanism? If so digital obliteration of the temporal artery as it crosses the zygoma on the affected side should relieve the pain. One wonders how many of the phenomena occurring in this patient may be due to the psychological disturbance produced by the attempt to discard an addiction of such long standing.

Powers of M.O.H. in Notifiable Cases

Q.—The answer to the question "What is a carrier?" (March 30, p. 512) states: "The medical officer of health has no power to coerce a carrier as he can a patient suffering from a notifiable disease." What authority has a medical officer of health to coerce such a patient? The Public Health Act 1936 (Section 169) gives a justice of the peace power to make an order to remove a patient suffering from a notifiable disease to a hospital or institution on the application of a local authority (not of the M.O.H. nor of the clerk or the chairman of the local authority) subject to all of the following conditions: (a) circumstances are such that proper precautions can not be taken or are not being taken, (b) that serious risk of infection is involved, (c) that accommodation is available in a suitable hospital, (d) that the consent of the superintending body of the hospital has been obtained.

A.—The above statement is correct but incomplete. Persons arriving by sea (Port Sanitary Regulations, 1933, Art. 31) or by air (Public Health (Aircraft) Regulations, 1938, Art. 16) who are suffering from an infectious disease may be removed to hospital by the M.O.H. on his own initiative. On the other hand, in the case of notifiable disease occurring in a common lodging house the patient may be removed to hospital by the

local authority without the intervention of a J.P. if the conditions stated in the question exist.

In practice, if the state of affairs is so serious under ordinary domiciliary conditions, the removal of a case is too urgent to await the decision of a local authority, which must take days and may take weeks. Every local authority should therefore give a general authorization to their town clerk and/or medical officer of health to act for the authority in an emergency of this kind, subject to a report being made on any such action taken.

Rheumatic Virus

Q.—Are streptococci the main aetiological agents of rheumatic fever and rheumatoid arthritis? Schlesinger and Sign (Lancet 1935 1 1145) reported on a virus associated with rheumatism but van Rooyen, Green and Slater (communication to the Association of Physicians, 1932) were unable to find any evidence for the existence of a rheumatic virus. What is the accepted view on this problem?

A.—The observations quoted consisted of demonstrating particles believed to be elementary bodies or virus particles, in the deposit obtained by high-speed centrifugation of rheumatic effusions (pericardial, etc.). These were said to be agglutinated by the serum of cases of rheumatic fever. Eagles and Bradley (Quart. J. Med., 1939, 8, 173), while confirming the existence of these bodies, found that they were agglutinated by serum from cases of other forms of arthritis, even including gout. The usually accepted present view is that these bodies are of some other nature altogether, they have never been proved—by demonstrating their infectivity—to consist of living virus. There is much evidence of several kinds that rheumatic fever is a peculiar response to infection by haemolytic streptococci and none pointing clearly to any other factor. The aetiology of 'rheumatoid arthritis' is more obscure, and these remarks do not apply to it.

Flitches, Fleas, and D.D.T.

Q.—I want to use D.D.T. on a dog. Can it be mixed in a powder with say zinc oxide, calamine, or starch and, if so in what proportions? I also want to use D.D.T. to protect bacon and hams. Is there an odourless, tasteless solvent? In what strength should it be used, and would it be dangerous to spray it direct on the flitches?

A.—For fleas or other vermin on dogs and other animals D.D.T. can be used in the form of a 10% powder in any inert diluent (talc, kaolin, starch, etc.). There are several preparations of this type on the market with a declared D.D.T. content on the bottle.

The problem of protecting bacon and hams from the cheese skipper (*Platylabus casellus*) which commonly attacks them is more difficult. Since D.D.T. is to some degree poisonous when in solution in oils or fats it should certainly not be sprayed direct on to the hams. In this connexion it may be noted that the Minister of Health said recently in Parliament that, according to present knowledge, there was little risk attaching to the use of D.D.T. in the form in which it is commonly applied—namely, as a powder or a watery suspension. Further investigations were proceeding into the toxicity of D.D.T. in oily solution. In any form D.D.T. should be kept away from food since taken internally it was harmful.

Skin Reactions to Mepacrine

Q.—Can you tell me anything of the aetiology, signs, and treatment of a lichen-planus like eruption associated with the taking of mepacrine?

A.—It has been recognized for some years that the taking of mepacrine provokes a variety of skin reactions in certain individuals who have an idiosyncrasy to the drug. These reactions may take the form of erythematous or eczematous—often weeping and sometimes infective—eruption, but the most distinctive reaction is that resembling lichen planus and commonly assuming a hypertrophic form. The condition may be extraordinarily widespread, involving head and face as well as any or all other parts of the body, including mucous membranes. The head and face are rarely involved in ordinary lichen planus. The condition may be of an extreme hypertrophic and warty type so that the patient looks like a tree-

trunk, but the colour and infiltration and buccal lesions suggest the diagnosis of lichen. All the hair may fall, as I have observed in some cases, and it is stated that scarring may result. Ulceration may also occur, especially about the lower legs, and itching may be marked.

While the condition is of great severity and the appearance of the patient is alarming, there is not, in those cases I have seen, any serious constitutional disturbance. The affection runs a prolonged course of several months and recovery seems to be complete, apart from the possibility of scarring previously mentioned. No specific remedies are recommended as yet, treatment being along the lines of that employed in lichen planus. I have found fractional doses of x rays of value in the later stages.

Protein Synthesis

Q.—What is the site of, and what controls, protein synthesis in the body? Is the mechanism known whereby preferential synthesis of predominantly acidic or basic proteins can be influenced?

A.—The cells of the body synthesize the proteins peculiar to their structure and function provided there is a suitable substrate from which to build. Caseinogen is produced nowhere in Nature but in the cells of the mammary gland. The main site for the synthesis of the proteins of the blood plasma is the liver, and Whipple and his colleagues believe that most of the protein synthesis within the body goes on in this organ. The liver may produce those fundamental protein units for body nutrition and use, which are then elaborated by the cells of the body to suit their particular requirements.

The rate of synthesis of protein by the cells is dependent on their special role and on their natural response to growth and to the other requirements of the body—for example, those concerned with reproduction—and on the supply in optimal amount of those amino-acids which the body cannot synthesize. The work of Whipple and his colleagues shows that there is a dynamic equilibrium between plasma protein and cell protein, the protein flow from cell to plasma or from plasma to cell depending on prevailing conditions. Reserve stores of protein out of which the body can produce haemoglobin in anaemia to removal of blood, or plasma protein in hypoproteinaemia, be demonstrated in the dog. Fibrinogen is among the most plentiful of the plasma proteins; liver injury may reduce it and acute infection or tissue injury may raise it. Diet may also modify its level. Protein production in the anaemic and plasma-depleted dog occurs from almost any protein or mixture of essential amino-acids. Whipple and his colleagues consider that it may be found possible to influence the ratio of plasma protein to haemoglobin. They found in dogs that the amino-acids necessary for growth supply the material out of which abundant plasma protein and haemoglobin can be produced, and that the presence of methionine in the mixture tended to favour haemoglobin production, and cystine plasma protein formation.

Haemoglobin cannot apparently contribute to the body protein pool except when the red cell is broken up. Haemoglobin is then saved, supplemented, and recast into new protein, depending on the body's needs. Whipple *et al.* have shown that much of this rescued haemoglobin or globin may contribute to the building of plasma proteins. In their view, then, the circulating plasma protein is the medium of exchange between the protein pool and the haemoglobin, new plasma, or cell protein.

It is difficult to determine what the questioner has in mind with regard to the latter part of the question. The acidic and basic properties of amino-acids are dependent on the relative proportions of carboxyl groups to amino groups. Thus the basicity of proteins is conditioned by the proportion of the diamino-acids—lysine, histidine, and arginine. Lysine must be provided in the proteins of the diet, and there is evidence to suggest that the same is also probably true of histidine and arginine. The basic proteins are the protamines and histones. The nucleoproteins are formed of a phosphorylated organic acid, nucleic acid with a basic protein which is usually a histone or protamine. As a whole the nucleoproteins have acidic charac-

ters although their protein component is essentially basic. Proteins of an acidic character are the phosphoproteins, which have a high content of dicarboxylic groupings.

Protamines form the bulk of the protein of the nucleoproteins of ripe sperm cells and ova. Histones are not so strongly basic as the protamines. They occur in unripe germ cells, in lymphoid tissue, and as globin, the histone of haemoglobin. The most important phosphoproteins are the caseinogen of milk and the vitellin of egg yolk. Their biological function is to provide food material for the developing embryo or the growing young. The acidic character of caseinogen is due to its content of glutamic acid. The synthesis of protamines and phosphoproteins is thus mainly located in those organs which are concerned with reproduction. The questioner will find much of interest in the following articles or books: Whipple, G. H., and Madden, S. C., *Medicine*, 1944, 23, 215; Miller, L. L., *et al.*, *J. exp. Med.*, 1945, 81, 405; Kay, H. D., *Nature*, 1945, 156, 159; *Chemistry of the Proteins*, 1938, by Jordan Lloyd and A. Shore (Churchill); *Biochemistry and Morphogenesis*, 1942, by J. Needham (Cambridge University Press); *Advances in Protein Chemistry*, 1944, edited by M. L. Anson and J. T. Edsall (Academic Press, New York, vols. 1 and 2); Robschey-Robbins, F. S., Miller, L. L., and Whipple, G. H., *J. exp. Med.*, 1943, 77, 375; and Berg, C. P., *Ann. Rev. Biochem.*, 1944, 13, 239.

LETTERS, NOTES, ETC.

Causation of Schizophrenia

Dr. W. LEES TEMPLETON (Highgate) writes: With reference to the conclusion arrived at by your correspondent (March 16, p. 419) that, since the incidence of schizophrenia does not go up in wartime, hardship and stress are *not* the factors which have a causative effect in this condition. One would like to know how the figures for the 1914-18 war were calculated, as one's own experience of such cases some years after the conclusion of the war led one to think otherwise. In a series of well-developed cases investigated in 1923 the conclusion one came to in practically all was that, had there been no stress (and in 90% of the cases this stress was directly due to the war), it was doubtful if, in spite of the hereditary "make-up" present in all but one, any of them would have broken down at all. In other words, left in their own environment their powers of adaptation to the average stresses of normal life would have been adequate. Beyond this average it was not. It will be interesting to learn in later years if the weeding-out of the so-called psychological misfits by the psychiatrists of this war has, in fact, reduced the incidence of psychosis. Industrial psychologists with a long pre-war experience have cast some doubt on the value of many of the tests of the Army "trick cyclists." One hopes that there will be a thorough check up on the cases of psychoses of the next few years with their Army medical history, so that the value of a psychological pre-enlistment investigation may be calculated. After all we are likely to have a large peacetime Army, apart from the value of the findings in the sphere of industrial psychology.

Acute Pancreatitis

Dr. EVA McCALL writes: Mr. Norman Godfrey's article (Feb. 9, p. 203) recalls a case which was under my care in a military hospital during the first world war. The patient was sent to us from an auxiliary hospital in the neighbourhood with the diagnosis "gastritis." When I saw him he was apparently quite comfortable and I could detect nothing abnormal in the abdomen. After a week in bed on light diet and gastric sedatives he was allowed up on ordinary diet, and as the hospital was a clearing station it was decided to transfer him to another hospital in a neighbouring county where beds were less urgently needed. He was passed fit to travel by the orderly officer, but by the irony of fate he was seized with acute pain en route and died before reaching his destination. The necropsy revealed haemorrhagic pancreatitis. At this distance of time it is difficult to recall all the circumstances of the case in detail, but I always blame myself for having failed to make the correct diagnosis and for allowing an abdominal patient to undertake a railway journey.

Proctalgia

"A MEDICAL WOMAN" writes: I have read with interest the various letters which have recently appeared in the *Journal* describing attacks of pain in reference to the rectal area. It was stated by the writers, who are all men, that they had never come across a case in a female. It may therefore be of interest to state that I myself am a victim and frequently suffer from attacks which correspond in every point with those described. My mother also had similar attacks, and so does a female cousin on my mother's side of the family.

SOME RESULTS OF TRANSFUSION OF BLOOD TO RECIPIENTS WITH
"COLD" AGGLUTININS

BY

K. E. BOORMAN

B. E. DODD, B.Sc.

J. F. LOUTIT, D.M.

AND

P. L. MOLLISON, M.D.

Report to Medical Research Council from the South-West London Blood Supply Depot

Landsteiner and Witt (1926), and later Landsteiner and Levine (1926, 1929), drew attention to the existence of anti-A, agglutinins in the sera of some bloods of subgroups A₁ and A₂B. Landsteiner and Levine (1926) also noted that the sera of some bloods of subgroups A₁, A₂, A₃, A₄, B contained an agglutinin which reacted with bloods of subgroup A₁. This latter agglutinin was designated as a₁, and later by Thomsen (1932) as anti-O. As well as these specific cold agglutinins, Landsteiner and Levine (1926) described non-specific cold agglutinins, or auto-agglutinins, existing in the sera of bloods of all groups. All these agglutinins were generally weak, and reacted best in the cold or at low room temperature.

Such agglutinins under certain circumstances may become active at body temperature (37° C.). The instances described in the literature are as follows:

Anti-A.—Wiener (1941) and Young (1945) have each described a case of acquired haemolytic anaemia in which anti-A, agglutinins active at 37° C. developed after transfusion and were therefore presumed to be immune agglutinins. Race *et al.* (1943) also noted an immune anti-A, agglutinin active at 37° C. in a woman post partum. Young (1945) described in addition a case—a man of group A₁—who received a massive transfusion of group O blood and plasma. Some days later his serum was found to contain an anti-A, agglutinin active at 37° C., presumably derived passively from the natural anti-A, agglutinin of the plasma and the group O blood transfused.

Anti-O.—Davidsohn (1942) has reported a case in which such agglutinins active at 37° C. developed in the serum of a person of subgroup A, after repeated transfusions.

Auto-agglutinins.—Reisner and Kalkstein (1942) described auto-agglutinins active at 37° C. in a case of acquired haemolytic anaemia. Wiener (1942) described another such auto-agglutinin in a child with *Staph. aureus* septicaemia with anaemia, presumably haemolytic. Baar (1945a, 1945b) has noted three cases with acute or subacute liver necrosis and haemolytic anaemia whose serum contained auto-agglutinins active at 37° C. He describes these agglutinins as anti-O, but as they acted in each case also on the subject's own red cells they are, in the present state of knowledge of red cell antigens, probably better termed auto-agglutinins.

Apart from Young's case, in which the anti-A, agglutinin was derived presumably from the transfused group O blood and plasma, all these cold agglutinins active at body temperature can be explained as being the result of a process of immunization or auto-immunization, and naturally occurring atypical cold agglutinins active at 37° C. do not seem to have been described.

The possibility that cold agglutinins played a part in transfusion reactions was in the past a cause of great controversy (see Kilduffe and DeBakey, 1942). In the last five years it has been shown that the cause of most of the severe and hitherto unexplained haemolytic transfusion reactions is the Rh group of antibodies, which are usually warm agglutinins. The problem, therefore, of the cold agglutinins was left largely unsolved, though no well-documented case of a haemolytic transfusion reaction due to a cold agglutinin has been recorded (Wiener *et al.*, 1941). In the present paper some observations are presented which confirm the view that atypical cold agglutinins in-

active at 37° C. do not cause destruction of transfused erythrocytes. The observations also show that such agglutinins may undergo an immune response following the transfusion of blood containing the homologous agglutinogens and become active at 37° C.; they then may cause blood destruction, and must be taken into account in the selection of blood donors.

Case I

This patient, who had a mild hypochromic anaemia as a result of menorrhagia, was of group A₁M. Her serum contained an anti-A, agglutinin with a titre of 16 at 5° C., 2 at 18° C., and 0 at 37° C. After hysterectomy she was transfused with 380 ml. of A₁N blood, carefully warmed, and with 1,000 ml. of group OM blood which was not warmed. A slight increase of titre of the anti-A, agglutinin was noted on the eleventh day after transfusion; the titre was then 64 at 5° C. and 4 at 18° C., but the agglutinin still could not be detected at 37° C. Both the group O and the group A, cells survived normally; about 25% of the cells of each group were present 80 days after transfusion.

Comment.—A patient with anaemia from haemorrhage who has atypical "cold" anti-A, agglutinins in the serum was transfused with A₁ blood. The A₁ blood survived normally. There was a slight increase of titre of the anti-A, agglutinins; the thermal amplitude did not reach 37° C.

Case II

A man aged 58 had over a period of months a series of haemorrhages of increasing severity from a gastric ulcer. He was of group A, Rh-positive, and his serum contained an anti-A, agglutinin whose titre was 4 at room temperature and 0 at 37° C. He was first transfused with group O blood and then, after a biological test (Wiener *et al.*, 1942) had given a negative result, with 430 ml. of A, Rh-negative blood, refrigerator-cold, in half an hour. There was neither clinical reaction nor rise in plasma bilirubin. An attempt to follow the survival of this blood was frustrated by repeated haemorrhages. Within five days, although the anti-A, titre had not altered, no A₁ blood could be detected in his circulation. 500 ml. of group A concentrated red cells was given, also without reaction. For ten days A₁ cells could be detected in his blood, but repeated haemorrhages were occurring. Multiple group O and two further group A transfusions were given without reaction, and A₁ cells were again detectable in his blood. Three weeks after the last group A transfusion the anti-A, titre had risen to 32 at room temperature, but was still 0 at 37° C. The haemorrhage ceased and a successful partial gastrectomy was performed.

Comment.—This case of anaemia from haemorrhage had an atypical "cold" anti-A, agglutinin in the serum. Four transfusions of group A₁ blood were given without incident. There was an increase of the anti-A, agglutinin titre, but a thermal amplitude to 37° C. was not attained. It was not possible to follow the survival of the A₁ blood quantitatively because of repeated massive haemorrhages.

Case III

A woman aged 44, group AB, with menorrhagia due to fibroids, was found to have an auto-agglutinin active at room temperature. A transfusion of 500 ml. of a group B concentrated red cell suspension

was given in 50 minutes. The temperature of the cell suspension was 5–10° C. At the cross-matching test before transfusion the donor's erythrocytes were completely agglutinated by the recipient's serum at room temperature, though not at all at 37° C. There was no rise in the recipient's serum bilirubin immediately after or five hours after transfusion, and 24 hours after transfusion a differential agglutination test carried out on a blood sample from the recipient showed the presence of the expected number of donor's erythrocytes.

Comment.—A case of anaemia from haemorrhage with atypical "cold" auto-agglutinins in the serum was transfused with blood as cold as possible. No haemolysis could be detected, and the transfused blood survived normally.

Case IV

This woman, aged 22, was first seen by us in April, 1942, when she had extensive tuberculosis and a haemolytic anaemia. She complained of cough, pains in the chest, and lassitude. On examination she was pale and slightly jaundiced. There were signs of bilateral pulmonary tuberculosis and enlarged glands in both sides of the neck (with scars of previous excisions) and in both axillae. The spleen was just palpable. In hospital she had a remittent fever to 102° F. (38.9° C.) and a pulse rate of 90 to 120. A blood count on March 17, 1942, had shown: red cells, 1.2 millions per c.mm.; haemoglobin, 26% (Haldane); leucocytes, 4,600, of which 81% were neutrophil polymorphs. Marked anisocytosis and polychromasia of the red cells had been reported.

At the end of March she had been given two transfusions each of 500 ml. of group O concentrated red cells without any appreciable rise in haemoglobin.

On April 23, when seen by us, her haemoglobin was 34% and the plasma bilirubin 2 mg. per 100 ml. Her red cells showed marked auto-agglutination; her blood group was A (later diagnosed as subgroup A₂). A course of transfusions, each of 1,000 ml. of concentrated red cells, was given—on April 24 group O, on April 28 group A, and on May 1 group A. Of the eight group A donors who contributed, seven were traced and found to belong to subgroup A₁. On each occasion cross-matching tests at 37° C. had shown the donor cells to be compatible, and there was no reaction to any of the transfusions.

On May 13, as it was desired to give the patient a further transfusion, her serum was cross-matched with several group A bloods at 37° C. Only one of these was compatible, the others being strongly agglutinated. This compatible blood and the patient herself were then tested, and were both found to belong to subgroup A₁. On account of this it was suspected that she possessed an atypical anti-A₁ iso-agglutinin. Her serum was then put up with a larger series of group A bloods at 37° C. The results confirmed that the iso-agglutinin was specific for A₁ cells.

Fig. 1, showing the anti-A₁ iso-agglutinin titre of the patient's serum at 37° C., demonstrates that there was an immune response to the injection of the group A₁ blood. The magnitude of this immune response makes it seem most probable that an anti-A₁ iso-agglutinin was present before transfusion, active at a temperature below 37° C. The graph gives no indication of an immediate immune response, but, had it been possible to titrate the anti-A₁ iso-agglutinin at lower temperatures before and during the first five days after transfusion, no doubt an increase in titre and thermal amplitude would have been detected.

It is interesting to correlate these observations with the clinical condition of the patient and the haematological findings. On May 8, one week after the last transfusion, she became deeply jaundiced and ill. The liver enlarged down to the umbilicus; the urine contained bile pigment, but the stools appeared normal. The haemoglobin fell from 70% on May 2 to 17% on May 14. On this day there were no demonstrable A₁ cells in her blood, although there were still 375,000 per c.mm. (18% of the original count) group O cells from the first transfusion. The clinical features of sudden increase in jaundice and malaise suggested either a spontaneous haemolytic crisis or a delayed blood-incompatibility reaction. The presence of bile in the urine, which is not uncommon after incompatibility reactions, favoured the latter diagnosis; the complete disappearance of A₁ cells but not of the previously transfused O cells, together with the serological findings, makes the diagnosis practically certain. The patient was at this point again transfused without reaction with 500 ml. of group A₁ blood, 1,500 ml. of group O blood, and 500 ml. of group O concentrated red cells, which raised her haemoglobin to 70% the following day. By this time the jaundice had disappeared. Within the next two weeks the haemoglobin fell steadily to 38%, and then appeared to become stable at a level of 38 to 44%.

Comment.—This case of acquired haemolytic anaemia had in the serum auto-agglutinins and an atypical anti-A₁ agglutinin. When A₁ blood was transfused there was a marked immune response of the anti-A₁ agglutinin. One week after the last group A₁ transfusion, when the thermal amplitude of the anti-

A₁ agglutinin reached 37° C., signs of delayed blood-transfusion-incompatibility reaction appeared with massive haemolysis and elimination of the blood.

Case V

This woman, aged 37, with a full-term pregnancy, had a Caesarean section on July 21, 1942, after the rupture of the membranes. Three days later the temperature rose to 103° F. (39.4° C.). Subsequently *Staph. aureus* was grown from the cervix and *Staph. aureus* and haemolytic streptococci from the abdominal wound. Massive sulphonamide therapy was instituted. As the patient was of group AB, on July 26 1,000 ml. of group AB citrated blood and on July 29 500 ml. of group O blood were given. On July 31 the haemoglobin was 54%, and the leucocytes 12,500 per c.mm., of which 85% were neutrophil polymorphs. The erythrocytes showed slight anisocytosis and poikilocytosis and moderate polychromasia. Three normoblasts and two primary erythroblasts were seen in counting 200 white cells. Fifty-eight grammes of sulphathiazole and 19½ g. of sulphapyridine had been given in the preceding seven days. On Aug. 2 a further 1,500 ml. of citrated group AB blood was given, raising the haemoglobin to 75%. The donors of the last transfusion and the patient were found subsequently to belong to subgroup A₁B. The previous donors could not be traced. By Aug. 17 the haemoglobin had fallen to 38%. A further transfusion was contemplated, but homologous-group blood (AB) was agglutinated on cross-matching at room temperature. Moderate auto-agglutination was also noted (titre 2 at room temperature). Examination of her serum revealed an atypical anti-A₁ iso-agglutinin—titre 32 at room temperature and 8 at 37° C. Two transfusions of group B citrated blood and group B concentrated red cell suspension, both compatible on cross-matching, were given on Aug. 23 and 25. The haemoglobin rose to 62%. A further 62 g. of sulphapyridine and 7 g. of sulphadiazine had by this time been given.

Blood cultures, which had previously been negative, grew *Staph. aureus* on three occasions, the last on Sept. 15. Fifty-four grammes of sulphathiazole were given over four days during this time. She was first seen by us at this point. Transfusions of group B concentrated red cell suspension, 1,000 ml. and 750 ml., were given on Sept. 21 and Oct. 15 respectively, and the haemoglobin rose to 94%. Metastatic abscesses appeared, and were not finally cleared up until January, 1943.

The titre of the anti-A₁ iso-agglutinin was followed at intervals (Fig. 2). On Oct. 11, 77 days after the first transfusion, the thermal amplitude had fallen below 37° C.

On Dec. 2 a biological test (Wiener *et al.*, 1942) with 30 ml. of fresh group A₁N blood was negative. Therefore a transfusion of 450 ml. of A₁N citrated blood plus 200 ml. of A₁N concentrated red cell suspension and 300 ml. of group O MN concentrated red cell suspension was given. It is suggestive that, at the forty-third day after transfusion, whereas 39.5% of the group O cells were still in the circulation, there were only 9% of the group A₁ cells. By the fifty-sixth day all the A₁ erythrocytes had been eliminated, although 29% of the group O were still surviving. At this point the anti-A₁ iso-agglutinin was again active at 37° C., with a titre of 1.

A final course of sulphonamide therapy, 67 g. in nine days, was given, starting Jan. 5, 1943, because of a cross-infection of an abscess cavity with haemolytic streptococci. On Jan. 20, the haemoglobin having fallen to 40%, a transfusion of 500 ml. of group B concentrated red cell suspension was given. On Jan. 29 a biological test with 65 ml. of group A₁N fresh citrated blood gave a positive reaction—the serum bilirubin being 0.24 mg. per 100 ml. before the test and 0.8 mg. one hour afterwards.

Comment.—This was a case of haemolytic anaemia in which, as a result presumably of an A₁B blood transfusion, an atypical anti-A₁ agglutinin reached a thermal amplitude of 37° C. After the thermal amplitude had subsequently fallen below 37° C. a blood transfusion with A₁ blood was given, being well tolerated. Two months later the thermal amplitude again reached 37° C. and the A₁ blood had been eliminated, and a biological test showed that more A₁ blood was incompatible.

Case VI

A woman aged 32, group A₁B Rh-negative, had had a macrocytic anaemia refractory to treatment since her only pregnancy five years previously. She also had neurological symptoms and signs not conforming to the classical syndrome of subacute combined degeneration of the cord or of disseminated sclerosis. For one year she had had attacks of jaundice associated with the passage of urine "the colour of liver extract." Nine months previously she had been in hospital and was given three blood transfusions—the first two of group O, the third of group AB—all of which were followed by the development of jaundice and the passage of bloody urine.

On examination she was slightly icteric and markedly pale; the liver and spleen were not palpable. There were pallor of the optic disks, fine nystagmus on looking to the left, slight wasting of the

hand muscles, muscular weakness more pronounced in the upper than in the lower limbs, sluggish tendon-jerks in the arms, absent ankle-jerks and sluggish knee-jerks, and a positive Babinski response. There were no sensory signs. She had an anaemia of the haemolytic type—plasma bilirubin 3 mg. per 100 ml., reticulocytosis up to 30%, with grossly excessive urobilinogen in the urine. The erythrocyte fragility was not increased. A transfusion of group O Rh-negative blood was followed by haemoglobinuria for three days.

At this stage we were able to examine her blood. Her serum contained an agglutinin, or mixture of agglutinins, which agglutinated

at room temperature the red cells of 130 random bloods but not her own red cells. Three only of the bloods were not agglutinated at 37°C. These were of groups A,N Rh,rh, A,N rhrh, and A,BMN rhrh respectively. Three others were but weakly agglutinated at 37°C., and were of groups A,M Rh,rh, A,N Rh,rh, and A,MN rhrh. With the quantities of serum available differential absorption experiments showed no clear-cut mixture of agglutinins. A bottle of concentrated red cells was made with the two A₁ bloods not agglutinated at 37°C., and approximately 120 ml. was given slowly over a period of one hour without symptoms. A sample was then taken, which showed gross haemoglobinuria and no demonstrable A₁ cells by differential agglutination with anti-B serum. The transfusion was therefore stopped. A transfusion some days later with 400 ml. of reconstituted dried serum was uneventful and gave rise to no haemoglobinuria. The antibody or antibodies responsible for the haemolysis of the transfused blood could not have been anti-Rh agglutinins or "blocking" antibodies, as both Rh-positive and Rh-negative blood were equally eliminated. The properties of the agglutinin resemble anti-O—not the weak anti-O specific for group O and group A₁ blood as originally described, but the strong anti-O as produced by Hirzfeld and Amzel (1940) in the goat by immunization with Shiga antigen which agglutinated bloods of all groups, the group O bloods most powerfully and certain of the groups A₁ and A₂ bloods only weakly. It had the properties of a cold agglutinin in being stronger at room temperature than at 37°C., but the difference in titre was not great—average titre at room temperature 8 and at 37°C. 4. It is notable that bloods apparently compatible by careful cross-matching tests at 37°C. were incompatible *in vivo*.

Comment.—This case of acquired haemolytic anaemia had in the serum an agglutinin which *in vitro* reacted at room temperature with all red cells except the patient's own and at 37°C. with the great majority of bloods; *in vivo* even bloods without reaction at 37°C. were haemolysed. This may have been an anti-O agglutinin.

Discussion

Cases I, II, and III had in their serum natural cold agglutinins. In Cases I and II the agglutinin was of the anti-A₁ variety; in Case III it was an auto-agglutinin. In none of these cases transfused with blood, the red cells of which were agglutinated at room temperature but not at 37°C., was there any suggestion of a haemolytic transfusion reaction, even though, as in Cases II and III, no attempt was made to warm the blood to body temperature; in fact, on two occasions the blood was

purposely given at as low a temperature as possible. Moreover, where estimation of the survival of the transfused red cells was possible, this showed that the transfused blood survived normally. As a result of the transfusions in Cases I and II there was a slight increase in titre of the cold agglutinin. It is possible that if the antigenic stimulus had been applied often enough the antibody response might have been such that the agglutinin would have increased in thermal amplitude to body temperature. This apparently was so in Davidsohn's (1942) case, in which an anti-O agglutinin became active at 37°C. This was a case of repeated haemorrhage treated with multiple transfusions. It is probable that certain individuals are more susceptible to the blood group antigens than others; this is certainly so with Rh-negative individuals, as determined by their antibody response to repeated pregnancy with Rh-positive foetuses or to repeated transfusion with Rh-positive blood.

Nos. IV, V, and VI, in whose sera the atypical antibodies were active at 37°C., were all cases of haemolytic anaemia of the acquired variety—in Cases IV and VI of uncertain aetiology, and in Case V probably as a result of septicaemia. The cases of Wiener (1941),

Young (1945), Reisner and Kalkstein (1942), Wiener (1942), and Baar (1945a, 1945b), noted in the introduction, also appeared to be instances of acquired haemolytic anaemia. It has long been known that cold auto-agglutinins are to be found commonly in the sera of such cases. It would appear that these agglutinins may reach a thermal amplitude of 37°C. as a result of auto-immunization, aided perhaps by transfusions of homologous blood, or that they are associated with the auto-haemolysin responsible for the haemolytic process (Dameshek and Schwartz, 1940), as iso-agglutinins are associated with iso-haemolysins. The mechanism which stimulates the formation

FIG. 1.—Case IV. Immune response of anti-A₁ iso-agglutinin (titrations at 37°C.).

FIG. 2.—Case V. Immune response of anti-A₁ iso-agglutinin (titrations at room temperature and 37°C.).

of these non-specific cold agglutinins probably also stimulates, in the case of the appropriate blood group, the specific atypical cold agglutinins. This may account for the anti-A₁ agglutinins active at 37° C. in Cases IV and V and in the cases of Wiener (1941) and Young (1945).

In the selection of donors for cases of acquired haemolytic anaemia, and for puerperal women (especially the mothers of infants with erythroblastosis foetalis, who are known to be capable of responding to blood group antigens) of groups A and AB, one should therefore take cognizance of the subgroup of donor and recipient as well as of the major group and the Rh group.

The fact that it is possible to obtain by immunization, either by transfusion or by pregnancy, agglutinins specific and active at 37° C. for A₁ blood in recipients of subgroups A₁ and A₂B presents, as pointed out by Wiener (1941), conclusive evidence in support of the theory that there is a qualitative difference between the agglutinogens A₁ and A₂. Hitherto, however, the activity of these atypical agglutinins at 37° C. had been determined by tests *in vitro* only. Thus both Wiener and Young observed their agglutinins during cross-matching tests with A₁ blood, so that trials *in vivo* were not attempted. In Case IV, above, the specific anti-A₁ agglutinin was detected only after transfusion, and a delayed incompatible transfusion resulted, thus proving the specificity and activity *in vivo* of the anti-A₁ agglutinin. In Case V, above, the biological test of Wiener *et al.* also showed that the anti-A₁ agglutinin was active *in vivo*. Case VI illustrates that tests *in vivo* are more reliable than the routine careful cross-matching tests *in vitro*. The biological test of Wiener *et al.* would have demonstrated haemoglobin-aemia even earlier than it was detected in this case.

Summary

Six individuals whose sera contained cold agglutinins were transfused with blood.

In the first three cases, in which the atypical antibody present was a natural agglutinin active only below body temperature and in which the anaemia was due to haemorrhage, there was no clinical reaction even though the blood was transfused at refrigerator temperature; moreover, the transfused blood survived normally.

In the last three cases, in which the atypical antibody was an immune antibody active at 37° C. and the anaemia was of the acquired haemolytic type, incompatibility and rapid destruction of the transfused blood were demonstrated.

Cases of acquired haemolytic anaemia, and other cases in which immunization either by pregnancy or by repeated transfusions has occurred, need special consideration when being transfused. This applies not only to the Rh group of antigens but also to the subgroups of the A antigen.

Acute haemolysis of A₁ donor blood occurred in recipients of subgroups A₁ or A₂B, whose sera contained anti-A₁ agglutinins active at 37° C. This provides further and more conclusive evidence of a qualitative antigenic difference between the bloods of subgroups A₁ and A₂.

We should like to thank the following for permitting us to investigate cases under their care: Dr. Horace Evans, Mr. E. C. B. Butler, Mr. A. Perry, Mr. J. V. O'Sullivan, Mr. A. York Mason, Dr. H. F. Harwood, and Dr. F. Pounds.

MIGRAINOUS, CILIARY, AND POST-TRAUMATIC DURAL HEADACHES

BY

WILFRED HARRIS, M.D., F.R.C.P.

The object of this communication, part of which I presented before the Association of British Neurologists in June, 1945, is to stress the fact that three types of neuralgic headaches—migrainous and ciliary neuralgias and many post-traumatic headaches, either constant or recurrent—are susceptible of cure by the treatment of trigeminal block.

The migrainous and ciliary neuralgias, though fairly common, have been mostly neglected as supposedly incurable, the patients being either doped with analgesic and sedative drugs, which often fail even to give temporary relief, or else left alone to bear their recurrent painful attacks, often agonizing for hours or even days, for the long years from adolescence to late middle life, in the hope, often a vain one, that with the passing of the years they will ultimately gain their freedom. The slighter forms of migrainous neuralgia, lasting only a few hours at long irregular intervals, may well be left to carry on with or without analgesic sedatives, but it is the more violent and crippling types, which tend to become more and more frequent and longer-lasting as the years go by, that I claim deserve more drastic treatment, with the hope of permanent cure.

Post-traumatic headaches, following head injuries, also have often been diagnosed as "functional" and denied real treatment, and I wish to emphasize the fact that unilateral persistent or frequently recurring headaches after head injuries may be due to organic dural injury, and may persist for many years unless cured by trigeminal block in a similar manner to that which I describe for the migrainous neuralgias.

Since 1908, when I first began to use alcoholic injection of the main trigeminal branches for the treatment of tic douloureux, I have been able to separate at least three other main types of chronic facial neuralgias, totally different from trigeminal tic in their aetiology and yet often mistaken for it. Two of them are susceptible of cure by the same process of nerve block by destroying the whole or even the inner portion only of the Gasserian ganglion. A fourth type, which I described first in 1921 (Harris, 1921a, 1921b)—glossopharyngeal tic—is curable only by section or avulsion of the ninth nerve. In 1911 I began to use the terms "migrainous neuralgia" and "ciliary neuralgia" to describe two forms of severe unilateral neuralgia, recurrent and sometimes periodic, affecting the region around one eye and temple and upper part of the cheek, and even occasionally spreading behind the ear and down the side of the neck. In some cases the eyeball is the site of the pain, which then becomes congested and lacrimating. This variety of migrainous neuralgia I call ciliary (Harris, 1926b) neuralgia, because of the marked ocular congestion and the ring of peri-ocular reddening around the cornea. The pain differs in type from trigeminal tic in many respects, and instead of lasting only a few agonizing seconds it is sometimes continuous for hours at a time, sometimes for only ten minutes or less; but such short attacks are liable to be repeated frequently—perhaps 20 to 30 times in the 24 hours. Unlike trigeminal tic, the pain is not brought on by the movements of eating, talking, or handling the face. There is often a history of previous migraine in earlier years or in the family, and sometimes nausea is present, though vomiting is rare, and visual phenomena such as precede or accompany classical migraine are never met with. For these reasons I call this type of recurrent neuralgia migrainous rather than migraine, for I look upon it as an anterior type of migraine, and am of the opinion that its pathology is a vasomotor neurosis, sympathetic in origin, of the meningeal vessels, as compared with classical migraine, which appears to affect mainly the posterior cerebral vessels. This view I expressed in 1926 (Harris, 1926b); and again, in 1936 in two papers (Harris, 1936a, 1936b), that the afferent path of the pain was the first and second divisions of the trigeminal nerve, and therefore it was curable by partial Gasserian block of the inner two divisions.

Gasserian Block Injection

Earlier—1911 and onwards—I treated numerous cases of migrainous and ciliary neuralgia by alcoholic piqure in the temple

and of the supraorbital and infraorbital nerves, and many excellent results were obtained, with instant relief, in some cases lasting two to five years. I attributed the good results to reflex shock to the trigeminal system, though about 30% did not benefit. Since 1921 I have increasingly replaced the peripheral suture treatment for true nerve-block by injections of the Gasserian ganglion, and since 1931 I have used Gasserian injection almost exclusively for migrainous and ciliary neuralgias. By this method I have been able to achieve much more certain and longer-lasting relief, in many cases undoubtedly permanent on account of the destruction of the nerve cells in the ganglion, thus shutting off all afferent impressions from the dura by the recurrent meningeal trigeminal-branches. The following case is an example:

Case 1.—Mrs. H., aged 47, had suffered from periodic left supra-orbital neuralgia for four years before I saw her at St. Mary's Hospital in July, 1921. The pain lasted about eight hours daily from January to April in 1917, and again similarly the next year. In 1920 she had a more severe attack; and since then, from noon to 5 p.m., has never been free for a day. On Aug. 4, 1921, I injected the left Gasserian ganglion by the lateral route, causing total anaesthesia at first, which subsequently faded partially. Eighteen years later—on Sept. 28, 1939—she wrote in reply to a follow-up letter that there had never been any return of neuralgia, though the numbness was somewhat less, but she could not eat on the numb side. She was very well, and grateful.

Since that time I have published reports of many other cases of migrainous and ciliary neuralgias (Harris, 1926b) cured by Gasserian block injection (Harris, 1936a, 1940).

Usually it is unnecessary to anaesthetize the outer division or mandibular nerve with alcohol, using only a few drops of 2% novocain solution to numb the chin and lower lip as proof of the correct position of the needle point, and then, passing the needle through the foramen ovale for another $\frac{1}{2}$ in. (6 mm.), it is possible to destroy the inner two-thirds of the ganglion with alcohol alone. Before doing so it is advisable to watch the needle for a few seconds to see that there is no cerebrospinal fluid drip, which would indicate that the point is not in the substance of the ganglion but in the cave of Meckel. Should that be the case, the needle should be carefully withdrawn for about an inch (2.5 cm.), and the point depressed and then again pushed through so as to scrape through the lower margin of the foramen, when it is more likely to remain within the ganglion substance. Then inject 3–5 minims (0.18–0.3 ml.) of alcohol slowly according to the amount of permanent analgesia required. It will be noticed that little or no resistance is felt to the push of the piston—quite different from the resistance felt when injecting the third division at the foramen orifice. Should marked resistance be felt, the point is certainly not within the ganglion. Almost invariably such injection of the ganglion is followed in a very few seconds by marked conjunctival congestion and reddening, which may last for an hour or more. This is probably due to temporary paresis of the sympathetic vasoconstrictor fibres streaming over the dorsal side of the ganglion on their way to the ciliary nerves. Unless this congestion is observed, it is highly probable that the ganglion has not been properly injected, and that any analgesia produced will be temporary only. Thus it is possible sometimes to produce total trigeminal analgesia by injecting as much as 1 ml. slowly into the third division at the foramen orifice; but usually no ocular congestion occurs, and the resultant analgesia of the first and second divisions will probably disappear within an hour or two. Similarly, 3–5 minims (0.18–0.3 ml.) of alcohol into the inner portion of the ganglion is usually insufficient to produce permanent total anaesthesia, including deep pressure sense, and after a few days sensation to deep pressure and touch on the forehead will return, leaving loss of sharpness to pin-prick and loss of the corneal reflex, or even complete analgesia. This is usually sufficient to relieve the recurrent headache completely and permanently, with less danger of keratitis or trigeminal causalgia as a sequel.

Case 2.—A lady aged 43, single, had suffered for five years from attacks of pain like toothache across the right cheek in front of the ear, in the temple, over the eyebrow, side of nose, and cheek, and lately along the lower jaw, with occasional shoots in the side of the tongue. The headaches were daily, and were more or less controlled by tab. codein. co. or A.P.C. tablets. If no tablets were taken the pain would continue for two hours or more. No nausea, and never migraine. Edentulous since age of 18. Sinuses normal. Had had

a bicycle accident about the time the neuralgic headaches started. On Oct. 18, 1945, I injected the right Gasserian ganglion by the lateral route, using a 70-mm. needle, s.w.g. 20. The needle passed straight through the foramen without bone being felt, and C.S.F. dribbled, so the point was withdrawn $\frac{1}{4}$ in. (6 mm.), when the flow ceased. Four minims (0.24 ml.) of 90% alcohol were then injected without using any novocain. No pain was felt, and the face quickly became numb, with total trigeminal analgesia and slight congestion of the eye. Six hours later the third division was completely normal, but the first and second divisions were still totally analgesic, and she was complaining of headache on the left side, but had none on the operated side. Three months later, when I saw her, she was perfectly well, with no recurrence of the neuralgia.

Case 3.—A more instructive case, perhaps, is that of a public-school boy aged 14, whom I saw on Sept. 5, 1945, on account of increasingly frequent recurrent attacks of pain limited to the left eye during the past three years, he having had three attacks in the last ten days. If in a car or train when the eye pain was severe he would generally vomit. He looked very ill during the attacks, which lasted some hours. When 7 years old he was struck a heavy blow with an iron golf club over the left eyebrow, causing a deep cut and subsequent scar. Between the attacks he was quite well and active. There was no ocular congestion with the neuralgia. On Sept. 10 I injected the ganglion by the lateral route, using only 3 minims (0.18 ml.) of alcohol, so as to produce only light analgesia of the ophthalmic division and thus avoid any restriction of his activities at school. Total trigeminal anaesthesia, with no ocular congestion, lasted 24 hours; the next day sensation returned on the second and third divisions. A week later there was only light tactile anaesthesia of the first division, with partial analgesia, so I allowed him to return to school without any eye shade or paraffin eye drops. He had one headache in the first week, but practically no pain since, and when seen on Jan. 4, 1946, there was only light analgesia of V. 1 and V. 2, with diminished corneal reflex, so possibly his cure may be permanent.

Post-traumatic Headaches

It was the resemblance of many post-traumatic unilateral headaches to migrainous or ciliary neuralgia that led me to try the effect of Gasserian block in their treatment, and in the last five years I have thus treated 15 cases in which the unilateral headaches appeared to be the result of head injuries. In some cases the onset of the headaches was several years after the concussion; in others the pain dated from the time of the injury. In some the pain was constant, in others intermittent and resembling migrainous neuralgia, and in at least two the type of headache was typical of ciliary neuralgia—intermittent violent unilateral ocular pain, with congestion of the eye and lacrimation. Surgeons have been rather prone in the past to look askance at long-continuing headaches following head injury, to suggest the diagnosis of "functional," and to recommend treatment by that much-abused term "rehabilitation." Such was the general impression left by the opening addresses of Jefferson, Cairns, and Russell Brain (1941) at a meeting of the Neurological Section of the Royal Society of Medicine. Anyone who has watched the recurrent attacks of ciliary neuralgia in a case of previous head injury would surely be more tolerant in believing the pain to be real in many cases that have been diagnosed as functional on account of their long persistence. It is especially the unilateral headaches that call for active treatment when sinuses, teeth, and eyes have been examined and found normal. In support of my views on unilateral post-traumatic headaches the following six cases illustrate the result of Gasserian block, which I claim proves the organic nature of the headaches. Four of these cases I showed at the annual meeting of the Association of British Neurologists in June, 1945, when I read a paper on this subject.

Case 4.—S., when aged 33, was in the retreat on Dunkirk in May, 1940, was blown out of a lorry by a near bomb explosion, was unconscious for a few seconds, but was again got on board, and had to march the last ten miles to the beaches. He was without any food for three days until put on board a destroyer, which was at once torpedoed. When standing with his head about 6 ft. (1.8 m.) beneath her gun, the blast "seemed to take the top of my head off," starting a furious headache. Landed three days later, he was sent to Aldershot, where he had the first attack of right-sided headache that became recurrent, with pain like a bad toothache in the right eyeball, which would become bloodshot and lacrimating, the pain lasting 15 to 20 minutes. These attacks have persisted daily ever since, except for an occasional intermission of four or five days and once for five weeks. Often the attacks would recur every half-hour or so, day and night, and he might have as many as 30 in the 24 hours. He was attending a hospital in 1944, where the diagnosis of "functional" was made, when he was seen by Dr. Helen Dimsdale,

who recognized the case as one of ciliary neuralgia and sent him to me on July 20, 1944. On July 24 I gave him a small inner ganglion injection of 4 minims (0.24 ml.) alcohol, which produced temporary total analgesia of the first and second divisions; but this faded off after three or four days, yet he was free of neuralgia for three weeks. By the end of August the attacks were as frequent and severe as before, and on Sept. 4 I again injected the inner ganglion, this time using 6 minims (0.36 ml.) of alcohol. This caused instant pain in the eye and forehead, and marked congestion of the conjunctiva, with total trigeminal anaesthesia. Three days later V. 3 had recovered, but V. 1 and V. 2 were still total. Since then pressure sense and touch have returned partially, but complete analgesia persists still on V. 1 and V. 2. He has never had any return of the neuralgia, though he is subject to occasional "drawing" sensations around the right eye, with some feeling of pricking, quite different from his previous pain, and which he puts up with easily. They are probably of a causalgic nature.

Case 5.—D., aged 31, nearly ten years ago was knocked unconscious for two days in a so-called friendly boxing match. About three months later he began to suffer from intermittent headaches, sometimes weekly, or he might be free for a month. These attacks became more frequent, and lasted for several days, until I saw him on Feb. 13, 1945. The pain was always limited to the right side; there was no nausea, tenderness, or ocular congestion. On Feb. 16 I gave him a partial injection of the inner ganglion by the anterior route, injecting 5 minims (0.3 ml.) of alcohol after using novocain to the third division. This produced great ocular congestion and total trigeminal anaesthesia to all forms. By May 17 he had had no pain at all since the injection: the first division was still analgesic, but could feel pressure; the second division could not perceive pin-prick or touch, but felt hard pressure; the third division was normal. He has returned to work as a painter, and when shown at the meeting in June his condition was unaltered, and he was quite well and working.

Case 6.—Mrs. R., aged 41, had been subject to bad headaches across the forehead, and in 1943 fell unconscious for some seconds during one attack. In December, 1943, when she had influenza, she again fell unconscious and struck the right parieto-occipital part of her head. Since that fall the pain was continuous every day, sometimes seeming unbearable. The pain spread from the back of her head to the right side of the forehead and behind the ear, and the scalp was very sensitive in the region of the blow, though it had not been cut. When the pain was at its worst it would keep her awake, and the eye would lacrimate and the eyelids swell, the pain spreading under the eye; there was no vomiting. I saw her first on April 11, 1945. She had previously attended another "nerve" hospital, and had been told that her case was functional and she must attend her own doctor. On that day I injected her right Gasserian ganglion, first injecting the whole ganglion with a few drops of 2% novocain as a test. As this at once abolished the headache completely, I followed on with 5 minims (0.3 ml.) of 90% alcohol, with resultant total trigeminal anaesthesia, which was still unaltered next day; but there was no return of headache, and the tenderness of the scalp had disappeared. On May 25 there was still total anaesthesia of the first division, with slight return of sensation on the second and third divisions. She was feeling very well and experienced no pain. The condition remained unchanged when she was shown at the meeting in June.

An interesting point to note here was the very slight recovery of sensation on the second and third divisions, no doubt due to the previous infiltration of the whole ganglion with novocain, which prevented localization of the alcohol in the inner portion of the ganglion only.

Case 7.—C., aged 34, when a boy of 15 received a severe blow on the right side of the head, which was crushed by a lorry against a lamp standard, the scalp being badly torn on the right parieto-occipital region, where he bears an irregular scar 8 in. (20 cm.) in length. Headaches began on the right side a week later, four or five times a week, at first lasting as short a time as ten minutes, often four or five times a day. In December, 1940, he joined the Army, and in 1941 went through the North African campaign from Alamein, in the artillery, but the gun blasts made his headaches worse, and he was put to other work. The pains continued daily, and he was sent back to England in February, 1945. I saw him at St. Mary's on March 20, 1945. He gave a history of two attacks of migraine, one eleven years ago after falling on his face from a lorry, followed by numbness of the right lips, tongue, and face, with loss of speech for 20 minutes; and he had another similar attack in the desert during the campaign. On March 27, during an attack of headache, I gave him a Gasserian novocain test, which at once abolished the pain until sensation returned in about an hour. On April 9 I injected the ganglion with 7 minims (0.42 ml.) of alcohol, producing total trigeminal anaesthesia, which remained unaltered when the case was shown in June at the meeting; there had been no return of his headaches, and he had been doing regular work.

The following case is another good illustration of violent intermittent ciliary neuralgia developing six months after an extremely heavy blow to the head and face.

Case 8.—On Jan. 13, 1944, a man aged 36 was struck a violent blow across the occiput by a heavy iron girder when unloading a lorry, crashing his head against the asphalt road, cutting his right eyebrow, and fracturing his frontal bone, causing bleeding from the right ear, which is still partially deaf, conjunctival haemorrhages in both eyes, and bruising the whole face, which was much swollen. He was taken into an E.M.S. hospital, where he was kept for five weeks; he lost consciousness for a week after admission. He had a good deal of headache for several weeks, and then tried a light job, but six months after the accident he was attacked by a new kind of headache, which would start suddenly with pain behind the eyeball, the right eye becoming blood-red. These headaches might last from 20 minutes to four hours, occurring at first once a week or so, and latterly more often. From June, 1944, he had numerous petit mal attacks for the next six months, falling unconscious; these ceased in December, 1944. The pain would attack the back of the eye and above the eyebrow and the upper cheek on the right side, and has been so severe that he has walked the street at night in his pyjamas and dressing-gown, crazy with pain, and in April, 1945, he made an attempt at suicide by gassing himself. He was sent to me by Dr. Hinds Howell on June 30, 1945; his account of the recurrent neuralgic attacks was typical of ciliary neuralgia, and almost certainly a sequel to his head injury eighteen months previously. This case may be compared closely with Case 4, already described. I injected his inner ganglion with 5 minims (0.3 ml.) of alcohol on June 30, producing total anaesthesia of V. 1 and V. 2 which was still unchanged when he was seen on July 24, having had no more pain. In reply to a follow-up letter, he wrote on Feb. 24, 1946, that the numbness persisted on forehead and cheek, and the headaches were practically cured.

In my experience the ciliary neuralgias are more sudden in onset and more violent in character than the other form of migrainous neuralgia that I have described, though both forms show an undoubted relationship to migraine. What the cause of the ocular crises and congestion is in the ciliary form I have no suggestion to offer, beyond the inference that sympathetic disturbance is considerable. Their cure by trigeminal block seems sufficient proof that the painful stimuli are carried centrally by the recurrent meningeal trigeminal branches.

Case 9.—A girl—G., aged 21—was sent to me on Nov. 13, 1941 for almost continual right-sided headaches since the age of 14, never being free for more than a day or two. There was no vomiting with the pain. When 3 years old she fell from a height of two stories from a fire escape on to a concrete floor; profuse vomiting followed. On Nov. 20 a Gasserian novocain test dispersed the headache at once, so I then injected 4 minims (0.24 ml.) of alcohol deeply into the ganglion, producing total anaesthesia to all forms on V. 1 and V. 2. This has practically persisted unaltered, for when last seen on Aug. 31, 1944, only hard pressure was perceived on forehead and cheek, though V. 3 was completely normal. There has been no recurrence of the hemicrania. The depth of the anaesthesia persisting on V. 1 and V. 2, though only 4 minims of alcohol were used, may be compared with the similar result in Case 6, in which also a preliminary Gasserian infiltration with novocain was done.

Pathology of the Migrainous Neuralgias

What can be the mechanism of migrainous and ciliary neuralgias and post-traumatic headache? It seems inconceivable that the scalp can be the source of these afferent stimuli; there remain the skull and pericranium, the dura mater, pia-arachnoid, and the brain substance, in addition to the meningeal and cerebral blood vessels. The skull, brain substance, and pia-arachnoid are known to be insentient, and can be cut and burnt without any pain being produced. Penfield and his co-workers have shown that, though large areas of the dura are also insentient, yet in the region of the meningeal vessels and the dural sinuses stimulation or dragging and pressure on these structures may cause acute pain, which may be referred even down the side of the neck; and these stimuli are carried centrally by the afferent fibres in the recurrent meningeal branches of the trigeminal nerve, as can be proved by sectioning the posterior root of the fifth nerve or, as I have shown, by Gasserian nerve block. It is well known that intravenous injection of histamine produces no headache on the analgesic side after Gasserian injection. Penfield has insisted that it is the first division of the fifth nerve that is the most important in this connexion; I am entirely of the same opinion, as I have found that analgesia of the ophthalmic division is essential in the cure of migrainous

and ciliary neuralgia and many post traumatic headaches. Usually I prefer to obtain permanent complete loss to pinprick on the first division with light analgesia of the second division, while rarely is third-division analgesia required. Penfield and Norcross (1936) assume that in cases of severe head injury the brain slides across the face of the dura at the arachno-dural interface, and that it does not necessarily at once regain its former position. Then adhesions may form, which become stretched as the brain tends to return to its normal position and when these adhesions are attached to a sensitive area of dura, such as dural sinus or large meningeal artery, pain results. Rowbotham (1945) states that migraine headaches sometimes occur as a sequel to acute cerebral trauma or such headaches may be aggravated by head injury. He mentions visual spectra and hallucinations as occasionally accompanying the attacks, but I have never known these occur in migrainous neuralgia, nor in the post traumatic headaches that I have met with. Penfield and McNaughton (1940) have investigated the nerve supply to the dura, and they suggest that most of the dural branches even those which appear to originate from the second and third divisions of the Gasserian ganglion, really originate from the nerve cells belonging to the ophthalmic division. Penfield has found, during operations under local analgesia, that the dural sinuses and the large veins entering the sinuses are especially sensitive. The upper surface of the tentorium and the sagittal or superior longitudinal sinus, and the anterior fossa are supplied by branches from the ophthalmic division, while the middle fossa and the middle meningeal vessels are supplied from recurrent branches of the second and third divisions, but dissections and staining of the dural nerves entering the ganglion in the rhesus monkey suggest that those branches which appear to arise peripherally from the second and third divisions really arise from nerve cells in the ophthalmic division. He has found that stimulation of the anterior two thirds of the sagittal sinus may cause pain radiating downward into the neck, and I have occasionally noted that the pain in some migrainous neuralgias may be referred behind the ear and downward into the side of the neck.

Migraine

Not only migrainous and ciliary neuralgias may be thus successfully and permanently cured, but cases approximating more in type to migraine itself may also react equally well to the treatment.

Case 10—Mrs E., aged 50, had been subject to recurrent "bilious" headaches at her monthly periods since the age of 14. These were invariably on the right side and at first lasted 2 to 3 hours, but for the last four years the attacks had been more frequent and lasted longer—24 to 27 hours—though the menopause became established two years ago. The pain would be present on waking, always over the right eye and at the back of the eye, which was tender but not red, and vomiting began early. Phenobarbitone and aspirin only increased the vomiting. When I saw her on Jan 2, 1946, there were no abnormal physical signs, and the systolic blood pressure was 125 mm. There were never any visual spectra or other ocular phenomena. On Jan 7 I injected the inner Gasserian ganglion with 5 minims (0.3 ml) of alcohol while an attack was in progress, the pain ceasing instantly as soon as anaesthesia was produced. This was still complete on V 1 and V 2 next day, when she returned home. Five weeks later she wrote very gratefully, saying she had had no further trouble of any kind.

This case is unlike migrainous neuralgia on account of the profuse vomiting, and differs from most migraines in its relation to the monthly periods. I have had no opportunity of trying Gasserian injection in a case of classical migraine with visual spectra, but I think it very probable it might succeed equally well if the attacks were mainly limited to one side.

Atypical Neuralgia

A form of chronic facial neuralgia regarded in America as atypical is what I have described as chronic neuralgia of the jaws (Harris 1926a). This may affect the upper or lower jaw on one side only, or it may be bilateral. It is often described as a "drawing," "pulling," "burning" pain, constant, though varying in severity. I have known it follow massive extraction of the teeth. It is commoner in women than in men, and often a strong neurotic element is present. It closely resembles the causalgia which may follow Gasserian injection or root resection, when it affects the maxillary region, but in a few cases

it is restricted to the mandibular area. No treatment by nerve section or injection is of any benefit, and it is most important to recognize this type of neuralgia, as operation or injection often appears to make the patients worse, and the anaesthesia produced affords a further ground for complaint. The type of pain described by Sluder probably included this form as well as some migrainous neuralgias. Temporary improvement by cocainization of Meckel's ganglion or even of the Gasserian ganglion is of little value, if it relieves at all. Leucotomy might be considered in long standing depressed cases.

Summary

Unilateral headaches resembling migraine in some respects, affecting the region around the eye and temple, may be recurrent for years, and have hitherto been either classified as migraine or wrongly ascribed to ocular or sinus disorders, or else included under the term "atypical neuralgia."

A variety of migrainous neuralgia I have named "ciliary neuralgia," on account of the marked ocular congestion and lacrimation accompanying the ocular and periorbital pain in these cases. This type is often more violent and characteristic, but both these varieties of headache are curable by alcohol Gasserian injection and are no doubt due to vasomotor disorders in the meningeal vessels or dural sinuses. Since these areas probably have their sensory supply entirely from the recurrent meningeal trigeminal branches, their cure by Gasserian block is to be expected.

Post traumatic headaches may be of either of these two types of migrainous neuralgia, or they may take the form of a constant pain.

When they are unilateral and persistent for months or years it is probable that they are organic and not functional, and that they are due to dural adhesions resulting from the cerebral trauma. Gasserian nerve block by novocain injection should be tried, if possible during the headache. If this is successful in at once abolishing the pain, then 5 minims (0.3 ml) of 90% alcohol should be injected deep into the ganglion, permanent cure often results if the analgesia of the first and second divisions persists.

The same results may be obtained by surgical treatment, sometimes of the meningeal scar itself, if it can be found, or by reversed subtotal posterior rhizotomy, by cutting the inner ophthalmic fibres close behind the semilunar ganglion, in place of the usual subtotal resection of the outer portion of the root, as used in Frazier's operation for trigeminal tic. Whether Gasserian injection or surgical resection is preferred is a matter for the individual choice of the operator. Both have much the same effects, but I claim that the injection method is the more delicate, and preferable in the majority of cases; moreover, it is free of all risk to life.

THE CATHETER AND THE PROSTATE*

BY

WILSON H. HEY, F.R.C.S.

Honorary Surgeon, Royal Infirmary and Christie Hospital,
Manchester

If the prostate is removed with the strict asepsis of the neurosurgeon I have proved that the dangers of prostatectomy are enormously diminished†. The microbe, as ever, is our foremost enemy. In-dwelling rubber tubes, whether suprapubic or transurethral, are high roads for infection. The normal urethra is usually a mildly infected channel, and the prostate-blocked urethra almost invariably so. In over 200 cases I have shown that sudden decompression of the chronically well-distended bladder is beneficial, provided that the operation is aseptic and the prostate at the same time is removed, because in some cases the prostate may block the ureters as well as the urethra.

* Being a portion of a paper read before the Medical Society of London on March 11, 1946.

† *Brit. J. Surg.*, 1945, 33, 41.

My operation, briefly, entails a twelve-hour preparation with chemotherapy, low spinal anaesthesia, never as high as the umbilicus, a rapid emptying of the bladder even if it holds five pints (2.8 l.) of chronic residual urine, a gentle prostatectomy by the transvesical route, and the excision of the trigone extending almost to the ureters and the interureteric bar so as to make the bladder one with the prostatic cavity. Bleeding is patiently controlled by my diathermy haemostat. Ligatures are never used in the course of the whole operation. Every moribund piece of tissue is meticulously removed, thus providing conditions favourable to the continuance of asepsis. A thin-walled urethral tube is passed invariably in a retrograde fashion in order that the bladder and prostatic cavity can be drained for a few hours or a very few days. Clotting is prevented by sodium citrate and the bladder is securely closed.

This operation produces so little shock that other major operations are often performed at the same sitting. The patient gets up the next day. The blood urea descends far more rapidly than after simple suprapubic drainage, when it invariably rises for a time, frequently resulting in a higher mortality than prostatectomy itself. The patient's total stay in hospital is usually two weeks, and is often less. The mortality in 565 consecutive cases was 4.3%. This compares favourably with the pre-operative and post-operative mortality of other methods. The risks are diminishing with improvements in anti-infective technique. Perhaps, more important, a profoundly septic incident in the life of an old man has thus been avoided and he reports later with aseptic urine instead of that lifelong low-grade infection so frequently met with in the two-stage operation. This aseptic procedure permits a far higher standard of operability. Only eight out of 573 cases were refused operation, and those that were accepted included twelve cases with initial blood ureas of well over 200 mg. per 100 ml.

Exactly 75% (18) of the deaths were due to uraemia; and post-operative increase of uraemia is always due to infection. The commonest cause of infection is the catheter, usually passed by the practitioner for the relief of acute retention or, in the endeavour to avoid a prostatectomy. In my earlier cases I occasionally infected the patient by an antegrade passing of a drainage catheter at the end of the operation or by a cystoscope. By a simple technique a retrograde passage of a tube is now always possible. At least two weeks should elapse after the dilatation of a stricture or the passage of a cystoscope before a prostatectomy is done.

The following table shows the results in these 565 cases both with and without catheterization or other instrumentation.

Results of Instrumentation (Usually Catheterization)

	Without Instrumentation		With Instrumentation		Total	
	No.	%	No.	%	No.	%
Temporary suprapubic leakage	5	1	19	19.9	24	4.3
Epididymitis	3	0.6	8	8.3	11	1.9
Mortality	15	3.2	9	9.4	24	4.3
Average length of stay in hospital after operation	12.9 days		23.3 days		14.8 days	

These figures surely suggest that all cases of retention of urine, complete or incomplete, should be operated upon before a catheter is passed and that all dubious prostatic obstructions which require investigation and instrumentation should be left for some weeks to permit complete recovery. If the pre-operative catheter can increase the chance of temporary suprapubic leakage by 20 times it is a nuisance; if it increases the risk of epididymitis by 14 times it is a menace; and if it trebles the mortality it may be a lethal weapon.

The in-dwelling catheter is a minor offence compared with the suprapubic tube with its microbes clamouring for admission from above. Suprapubic drainage for any form of prostatic obstruction should be abandoned—even if it is performed for the relief of patients with blood ureas over 200 mg.; to this uraemia is added the uraemia produced by infection, and thus the patient's end is often hastened.

Summary

An earnest plea is made for the application of the principles of "absolute" asepsis in prostatectomy.

Two-stage operations and suprapubic drainage should be abandoned.

Proof is established that the catheter should never be used before prostatectomy.

Acute prostatic retention demands immediate operation. It is suggested that "aseptic prostatectomy" is at least as safe as catheterization.

FATIGUE SYNDROMES IN WEST AFRICA

BY

SIMON F. LINDSAY, M.B., Ch.B.

Capt., R.A.M.C.

The purpose of this article is to record some observations made upon a number of British Army personnel seen in regimental M.I. rooms in West Africa Command during a tour of duty there. They showed signs of physical and mental fatigue, and were chosen for study because they seemed to illustrate the relation of climate to ill-health in the moist Tropics. In many cases climate in itself appeared to be only a contributory cause in the presence of other factors, such as toxæmia and mental disharmony. An attempt has been made to analyse the aetiology of the various fatigue states described, and to show the role of climate as a cause of such illness.

Clinical Findings

The cases, 86 in number, were classified as follows:

A. Fatigue syndrome:	Cases
(1) Presenting characteristic signs of simple physical and mental fatigue	41
(2) Presenting signs of exaggerated or abnormal psychological reactions	14
(3) Related to toxic illness	9
B. Psychoneurosis—showing signs of fatigue	16
C. Depressive state—with fatigue	3
D. Psychosis—with fatigue	1
E. Post-concussion syndrome—with fatigue	2

A. Fatigue Syndrome

Subgroup 1.—The presenting picture resembled that found in any state of fatigue following prolonged physical or mental exertion. The amount of exertion and the degree of fatigue were disproportionate, and the only additional stress factor recognized was the exhausting nature of the climate. No mental anomalies were observed, and the patients, who represented a variety of constitutional types, had all succeeded in adjusting themselves to their environment. The symptoms were tiredness, lassitude, headache, forgetfulness, slight loss of interest, impaired powers of concentration, and mild depression.

Case 1.—Warrant officer aged 30; six months' service in West Africa; good health previously. Became easily tired, with headache and difficulty in concentrating in a rather noisy workshop. Relieved by short spells of lighter duty in quieter surroundings.

Case 2.—Officer, aged 35, of strong constitution and dynamic personality; 17 months' service in West Africa. Became easily tired, with headache and difficulty in concentrating, and was unrefreshed by sleep. He adjusted his economy of energy output and remained fit for duty.

Case 3.—Officer of asthenic type; complained that soon after coming to the Tropics he became lethargic, with faulty memory and reduced power of concentration. Slight general retardation persisted, but the patient remained happily adjusted to the disability.

Subgroup 2.—Here fatigue was the dominant feature in a state resembling simple anxiety neurosis of recent origin. These cases gave no previous history of neurosis, and showed no gross psychopathic traits, although in some instances seeds of neurosis were present. They expressed no personal anxieties other than a concern about the exhaustion and nervousness which had overtaken them. Timid and emotionally immature types appeared to be particularly prone to develop this more severe manifestation of fatigue. Most of these patients improved with rest, reassurance, and in some cases mild sedation. Only one required to be admitted to hospital. A number of

them were met by chance in another station nine months later, and they all appeared to be in good health

Case 4—Aged 28, 12 months' service in West Africa; average physical constitution; rather timid. Became tired, depressed, tremulous, and worried about his condition. After adequate rest and reassurance, he recovered sufficiently to justify continuation of service in the Tropics

Case 5—Aged 22, good athlete, 12 months' service in West Africa. Became extremely tired, with "lead-like limbs," tremor of hands and voice, and mild depression. He was distressed about the symptoms, which were quite new to him. A short course of mild sedation was followed by marked improvement

Case 6—Aged 20, physically fit, with no history of previous nervousness. He became easily tired after 10 months' tropical service. Soon fatigue was pronounced, with depression, marked anxiety, profuse sweating, inability to concentrate, loss of interest, and fear of insanity which was alleviated by reassurance. This patient did not respond well to treatment, and had an anxiety neurosis when he left the Tropics shortly afterwards

Subgroup 3—Fatigue syndrome such as described above was a common sequel to fevers and toxic illnesses—e.g., malaria, amoebic dysentery, food poisoning, and furunculosis. In connexion with malaria, a number of patients suffering from chronic fatigue were found to have malaria parasites in their blood. Sometimes fatigue was accompanied by anxiety and mild depression, which usually responded to rest and reassurance. However, convalescence was slow and some degree of disability persisted for several weeks as a rule, sometimes even for months. Retarded convalescence appeared to be largely due to the influence of the climate

Case 7—An officer, after eight months in West Africa, had a severe attack of amoebic dysentery, which was followed by physical and mental fatigue so persistent that he was invalided home

Case 8—An officer suffered from fatigue and a mild anxiety state following tonsillitis. The symptoms resolved with adequate rest

Case 9—A sergeant clerk, aged 25, with 26 months' total service in West Africa, developed a mild anxiety state with depression, head ache, listlessness, and inability to concentrate. Inquiry revealed that he had been tired and depressed on several occasions in the Tropics especially after each of a series of attacks of malaria. A conscientious, rather obsessional man, he responded very well to treatment and completed his full tour of duty with a maintained improvement in health

B. Psychoneurosis

In this class the clinical picture was predominantly that of a psychoneurosis such as one finds in temperate climates. In all cases there was definite evidence that neurosis had manifested itself prior to tropical service. Here the element of fatigue was more severe than one would expect to find accompanying the same neurosis in a temperate climate. It seemed that this fatigue must be largely due to climatic stress. These patients had been accustomed to the discomfort of neurosis and affective reactions were milder than in the fatigue syndromes described in Class A, where neurotic feelings were being experienced for the first time and distress was consequently acute

Case 10—A corporal aged 22 reported sick during his second month of service in West Africa. He was suffering from fatigue, probably due largely to the heat, but he also described symptoms which revealed a clear picture of a psychoneurotic constitution, with a positive family history. Obsessional traits were marked, and sleep-walking had occurred in childhood

Case 11—A staff sergeant aged 26 complained chiefly of fatigue, but there were signs of anxiety state and mild depression, with a history of similar illness before entering the Tropics

These patients had to be reassured from time to time, but were able to carry on satisfactorily. Included in this class were a few cases with features suggestive of true psychopathic personality. Traits observed were inability to settle at a job of work, lack of a normal sense of responsibility, emotional immaturity, and cyclothymic mood swings. Fatigue was not pronounced, but there was evidence to suggest that they had become emotionally less stable since entering the Tropics

C. Depressive State

Fortunately cases of severe depression were rarely seen. In these patients, all of whom required to be invalided, there were definite causal factors at work, which ruled out climate as a

primary cause. In fact, climate and environment seemed to play a minor part as a precipitating or aggravating influence. They all showed marked evidence of general fatigue

Case 12—A soldier aged 36 was seen, a few weeks after arriving in West Africa, with rather severe endogenous depression, morbid ideas of unworthiness, and a history of previous attacks

Case 13—A sergeant, aged 25, after nine months of satisfactory service in West Africa became tired and depressed, with an obsession that he was developing sleeping sickness. Seen after attempted suicide, he was very retarded. The case history revealed latent neurotic traits of long standing, and a domestic problem which had produced mental conflict since leaving home

D. Psychosis

Only one case was encountered—that of a senior N.C.O. He appeared at first to be an obsessively conscientious type who was becoming tired out. Soon he showed psychotic features, with grandiose and paranoid ideas and complete lack of insight. Inquiry proved that he had been a "difficult maladjusted" person in home units. Probably in this case the climate, together with other environmental factors, laid an additional strain upon a constitution already abnormal

E. Post-concussion Syndrome

Two patients were classified separately. The chief complaint was of headache and tiredness. Both had been concussed some years previously, and post-concussion syndrome had been diagnosed by neurologists in the United Kingdom. In addition, both had psychoneurotic traits, and climate seemed to act only as an aggravating factor in these cases

Discussion

Observers in different theatres of activity can be quoted in support of the theory that environment is only partly to blame for the fatigue syndromes and mental illnesses which occur under stress

Rodger (1943), in discussing effort syndrome in Iceland, lays emphasis on psychological predisposition, concluding that conditions of service in Iceland were not causative factors, but only aggravating to a minor degree. Stephenson and Cameron (1943), discussing anxiety states in the Navy, stress the significance of the degree of stability of the individual patient and the number of stress factors making for continued effort. Symonds (1943) in his lectures on human response to flying stress, describes a variety of stress factors, including fatigue of vision and hearing effects of acceleration and decompression, and anoxia but he concludes that "the emotional tension resulting from the prolonged exercise of courage is the most important element of stress". Craige (1944), reporting on military psychiatry in the Middle East, classifies the aetiology of psychological breakdown into predisposing factors (heredity, constitution, morale) and precipitating factors (domestic separation, climate, fatigue, and battle stress). Minski (1945), discussing psychological reactions in the wounded, says: "The degree of severity of a wound bears little or no relation to the development of a neurosis"

Millis (1945) describes experiments with white rats, showing that these animals are reduced to a slow pace of living by tropical temperatures, that their ability to ward off and fight infection is reduced, and that their capacity for learning and remembering is impaired. Similarly, meteorological conditions are shown to have certain effects upon human beings. When the barometer is low, restlessness, exhaustion, depression, and muddled thinking are common, with consequent feelings of frustration and hopelessness in some people. This is illustrated in West Africa, where spells of oppressive weather coincide with general depression, while favourable changes in temperature, humidity, and air movement produce a dramatic increase in vitality and elevation of spirits

Stewart (1945) describes heat fatigue occurring in industrial workers in hot weather, especially with high atmospheric humidity and diminished air movement. Adequate replacement of lost fluid together with sodium chloride proved to be an effective prophylactic. This also applies in West Africa, where the ingestion of fluid and salt after strenuous exercise speeds up recovery from fatigue

McDowall (1943), discussing man's biological adaptation to environment, writes as follows: "The effect of lack of mental

adaptation is dealt with in relation to conflict, where it seems that, just as excessive heat, cold, high altitude, or necessity to work hard or to fight brings about the bodily reactions which we group under the heading of increased sympathetic activity in animals, so also in man lack of mental adaptation brings about exactly the same bodily effects which if continued will have a seriously harmful effect on the happiness and health and length of life of the individual." And again: "Various mental states have a profound effect on the activity of organs of the body and may so disturb them that pathological states may result. There is indeed no hard-and-fast distinction to be drawn between functional upset and pathological states, for one may merge into the other. By far the most important change which occurs is increased activity of the sympathetic portion of the autonomic nervous system. . . . It occurs in forms of mental activity, involving alertness, attention, concentration, but is intensified in fear and in its antithesis, anger and rage. Anxiety produces less intense but more chronic states. Essentially the changes are those which prepare the animal for physical activity and make the muscles more efficient."

Good mental adaptation to life is characterized by a fair measure of satisfaction of the natural instincts—self-realization, sexual and social. Frustration of these leads to mental conflict, with varying response. Submission to circumstance may be a happy solution or may be accompanied by depression. Escape from conflict can be achieved by alcoholic over-indulgence and hysterical reactions. While, on the other hand, conflict may be allowed to continue, resulting either in a normal struggle against difficulties or in exaggerated responses such as the development of anxiety neurosis.

These mental mechanisms are all liable to colour an illness which at first sight might be considered due to climatic stress, and this applied to some of the cases seen in West Africa.

The 64 cases of fatigue syndrome referred to in this paper (Group A) were probably alike in their mode of origin and course of development, differing only in degree of severity, this being determined by several factors (internal and external)—physical constitution, personality, toxic illness, climate, and other environmental stress. In a few of the severer cases of fatigue syndrome it was thought that the term "tropical neurosis" was justifiable, because true neurotic reactions developed without previous history of such, and these reactions were not resolved by simple rest and reassurance, thus differing from many of the cases of sympathetic overactivity.

Conclusions

It would appear that everyone living in West Africa is liable to experience some degree of tropical languor, caused by the . . . Most people adapt themselves to the limitation thus upon their activities.

However, a certain proportion develop a fatigue syndrome which may lead to considerable disability. This is sometimes accompanied by overactivity of the sympathetic nervous system, so giving a picture of anxiety state which is usually temporary if it occurs in the absence of any other predisposing or contributory cause. The enervating climate may find in a weak physical or mental constitution fertile soil for producing its ill effects. Also, resistance to illness may be undermined not only by the climate but by other factors, such as toxæmia, excessive physical exertion, alcoholic over-indulgence, and psychological disharmony.

The West African climate appears to have an aggravating effect upon pre-existing psychoneurosis. Climatic stress can precipitate and aggravate depressive states and psychoses.

A few contributory factors require special note.

Physical Exertion.—When carried beyond a certain optimum period, undue fatigue results, with a delay in recovery.

Alcohol.—In strict moderation alcohol appears to be harmless, and is often a positive preserver of mental contentment. Too much alcohol is obviously harmful, lowering general resistance to illness in proportion to the individual's tolerance and the amount consumed.

Insomnia.—This is sometimes caused simply by the restless discomfort of hot nights, producing tiredness and irritability.

African Native.—Many people find it difficult to adjust themselves with equanimity to the ways of the African native, and this causes a feeling of frustration and irritability, with consequent tiredness and depression.

Finally, it is said that, when any struggle is prolonged, moral force, and not physical, will generally decide the issue. This seems to be true of West Africa, where the total personality, with its physical, intellectual, emotional, social, and moral components, must be considered when studying reactions to climatic stress.

I would like to express my gratitude to Brig. G. M. Findlay, C.B.E., Consultant Physician to West Africa Command, for permission to publish this article, and for much helpful advice; also to Lieut.-Col. A. C. Stevenson, R.A.M.C., formerly Assistant Director of Hygiene, West Africa Command, for his interest and advice.

IDENTICAL DEFORMITIES IN THE NASAL SEPTUM OF A PAIR OF IDENTICAL TWINS

BY

TOM O. HOWIE, M.B., Ch.B., F.R.F.P.S.G.

A review of the literature on identical twins shows many records of similar abnormalities in these siblings. The following are some of the conditions described: diabetes, allergy, thromboangiitis obliterans, epilepsy, exophthalmic goitre, otosclerosis, hearing defects, squint, polydactylism, inguinal hernia, hydrocephalus, congenital dislocation of the hip, hare-lip and cleft palate, and dental defects. There are only two recent references to nasal conditions. Furniss (1938) mentions the occurrence of mesial dermoid cyst of the nose in identical twins, and Pastore and Olsen (1941) record the absence of frontal sinuses and the presence of congenital bronchiectasis in identical twin sisters.

There has been no record of nasal septal deformities, and I feel that the case described below should be added to this considerable list. Some interesting conclusions can also be drawn from discussion of the occurrence of this deformity.

These identical twins, now aged 22, are serving with the Royal Air Force in the same unit. They were both admitted to the medical unit of an Emergency Medical Service hospital in October, 1945, suffering from bronchial asthma. They were referred to the ear-nose-and-throat department for examination, on account of suspected disease of the maxillary antra, which had been revealed during routine radiological examination of the paranasal sinuses. Their medical histories are interesting in connexion with allergic states in identical twins. Briefly they are as follows:

Twin No. 1

The patient had had attacks of wheezing since childhood. These start early in the morning, last approximately 24 hours, and are most common in summer; no cough or sputum. Occasionally there is sneezing. Otherwise he is healthy. He has a history of pneumonia at 2 years of age, bronchopneumonia in 1939, and attacks of eczema until leaving school. His father, mother, younger brother, and younger sister are healthy. The twin brother has a similar history to his.

Examination showed him to be well nourished. There was marked asthmatic wheezing, but no finger-clubbing. Respiratory movements were satisfactory. There was no chest deformity or impairment to percussion. Breath sounds were vesicular. Numerous inspiratory and expiratory rhonchi were heard. Vocal fremitus and resonance were normal. No other abnormalities were found, except changes in the antra seen in a radiograph of the paranasal sinuses.

Twin No. 2

Until May, 1945, this patient had had only a few mild attacks of asthmatic wheezing of short duration in the mornings. Since he went to France in May, 1945, the attacks have become much more severe. They always begin in the mornings and are aggravated by exercise. They do not coincide with his twin's attacks. He has noticed that eggs in the diet precipitate an attack. He had influenza at 9 years of age, and eczema mildly until leaving school. It was noticed that his brother (Twin No. 1) took illness much more severely than he

did. Respiratory and other examinations gave the same findings as in the case of his brother.

A rhinological examination carried out on these twin brothers showed that each had a severe septal deformity. These deformities were identical and were so gross that, had they been traumatic, they must have been produced by an identical trauma. One could only conclude that they were the result of a congenital malformation. There is so little variation between the two septa that a description of one will cover both cases.

The nasal septum shows a marked S-shaped deformity. There is a thick bony ridge, seen from the right side, extending almost from the anterior nasal spine backwards and slightly upwards. The ridge crosses the line of the inferior turbinate at the junction of the middle and posterior thirds. It touches the inferior turbinate at this point. In their lower parts the septal cartilage and perpendicular plate of the ethmoid lie over to the left, but higher up and more posteriorly they are displaced towards the right ethmoid capsule, and prevent any deeper view of the nasal cavity beyond this point.

The cartilage of the septum anteriorly is bent to form a pronounced step to the left, as if it had been dislocated from the bony groove in the maxilla and vomer in which it usually lies.

On inspecting the septum from the left side one sees a sharp, depressed gutter corresponding to the ridge or spur seen on the right side. This is overhung by the lower edge of the displaced septal cartilage. The septal cartilage is deviated anteriorly so severely towards the left wall of the nasal cavity that it prevents a free view of the middle meatus on this side. It touches the inferior turbinate near its middle third.

There are a few minor differences in the septal curves, but these hardly detract from the almost identical appearances of both nasal septa. One would immediately describe the deformities as reproductions of one plan of development.

Study of the radiographs taken shows that there is an almost exact similarity of the frontal sinuses—a point often noted in the investigation of identical twins. When the plates are superimposed the outlines coincide almost exactly. In the plate of Twin No. 2 slightly stronger markings of incomplete septa in the frontal sinuses are visible. The antra in both cases are exactly similar, and show a thickening of their mucous membrane lining, presumably allergic. The bony septal deformity can be clearly seen in both plates.

Discussion

Zuckerkandl (1892) gives a very full description of septal deformities. He contends that the massive ridge, or crista lateralis, almost always runs from the anterior nasal spine to the rostrum of the sphenoid. He points out that, even in cases of severe nasal injury with depression of the nasal bones, the cartilage may be deviated or fractured, while the bony septum is normal. The vomer remains quite straight, there is no sign of a crista lateralis, and the bend in the perpendicular plate of the ethmoid may be negligible. This has led him to believe in the existence of a physiological form—i.e., a deviation occurring in an intact nasal framework and a normal septum in which there is no question of injury.

Among possible causes he suggests the following: (1) irregular growth of one of the bony plates of the perpendicular plate of the ethmoid or of the vomer; (2) the continued growth of the septum where the maxillae remain undeveloped (this, he considers, would account for the relative infrequency of septal deformity in non-European races); (3) inheritance of a large nasal organ from one parent and a small upper jaw from the other.

StClair Thomson (1926), reviewing the literature on nasal septal deformity, shows that it is much more common in European than in non-European skulls: 75% of the former group show some degree of deviation. In primitive races it is very uncommon. The Red Indian, with his aquiline nose, seldom shows any deformity. This does not support the theory held by many that traumatism early or late in life is the commonest cause of septal deformity. StClair Thomson holds that heredity does not seem to play an important part in the transmission of a tendency to septal deformity.

Galton (1875) has shown that the study of twins affords a means of distinguishing between the effects which result from inherited tendencies and those which are imposed by external influences during their after-life.

It is well known that monozygotic twins are alike in their whole hereditary disposition, while dizygotic twins are, from the hereditary point of view, no more alike than ordinary brothers or sisters. The dissimilarity between monozygotic twins can be likened to that between the right and left halves

of the body of one person. Practically all differences in monozygotic twins are non-hereditary (cf. Verschuër, 1939). It does not follow, however, that all similarities are necessarily hereditary, since monozygotic twins have, more often than dizygotic twins, a much more uniform foetal environment (monochorial) (Pontecorvo, personal communication, 1946).

Conclusions

The deformity in the nasal septa of the identical twins described in this paper is congenital and may well be hereditary. Study of the septa of a series of monozygotic as well as dizygotic twins, and the investigation of pedigrees, are, however, necessary before a theory can be formulated, but I hope that the recording of this case may suggest a line of inquiry which would give a definite answer to the vexed question of the causes of septal deviation.

If such a developmental abnormality can be genetically determined, then a proportion of cases of septal deformity may be the result of an inherited tendency.

I have to thank Dr. James Johnstone, O.B.E., superintendent of the Emergency Medical Service hospital, for his permission to publish these records, and Dr. G. Pontecorvo for his advice on the question of heredity.

EXAMINATION OF THE LOWER UTERINE SEGMENT IN CASES OF SUSPECTED PLACENTA PRAEVA

BY

ALEX W. SPAIN, M.A.O., F.R.C.O.G.

Master, National Maternity Hospital, Dublin

It has become generally accepted practice that exploration of the lower uterine segment per vaginam in cases of suspected placenta praevia should be postponed until all preparations have been made for whatever form of treatment may be indicated by the individual case. In short, no exploration will be made until the operator is gowned, ready to perform Caesarean section.

In my earlier cases it was noted that quite a considerable loss of blood may take place in the time which elapses between the withdrawal of the examining finger and the delivery of the baby by section. In a few this loss occasioned much anxiety, and in some was the determining factor in rendering blood transfusion necessary. Happily, in no case was it fatal. The technique herein to be described will be found to prevent any serious loss at this time in cases where the cervix has not been taken up.

Technique

The method calls for the co-operation of a trained assistant. Either the operator or the assistant makes the examination while the other member of the team stands ready. The whole or half hand is introduced into the vagina; the index or middle finger is now inserted through the cervical canal and the placenta sought. I usually employ the middle finger as, owing to the situation of the cervix, the use of this finger causes much less crowding of the hand in the vagina. Should the placenta be found in the lower uterine segment, and should section be decided upon, the finger is gently withdrawn. If further placental separation has been caused by the examination haemorrhage will be at once apparent. In the event of such haemorrhage the cervix is grasped between the index and middle fingers. Very little pressure with these two fingers will be sufficient to close the cervical canal and thus check the bleeding. The cervix should be held in this manner until the operator has delivered the baby and the placenta.

A moment's consideration of the source of the haemorrhage will readily convince one that with the outlet blocked, and in the absence of active labour, bleeding must be limited to the area in which placental separation has already taken place.

Owing to the very low pressure to which the outpoured blood in the lower uterine segment is subject under such conditions, further placental separation will not be caused by the resulting haematoma. Thus a small limited haematoma will be formed similar to that found in normal third-stage placental separation.

In some of the earlier cases in which the method was employed I, in addition, pushed down the presenting part against the placenta, in the hope that by so doing the haematoma would be still further limited. This part of the technique I have now abandoned. It can be dangerous, especially in type II, III, or IV placenta praevia (Browne, 1944), in any of three ways: (1) by increasing the pressure within the artificially controlled haematoma it may cause further placental separation; (2) it may stretch the lower uterine segment, with a similar result; and (3) it may jeopardize the life of the foetus by diminishing the placental circulation: especially may this be the case if the cord gets its insertion low in the placenta—a factor of great importance in placenta praevia to which attention has been directed by Macafee (1945).

Results

The technique above described has been in use at the National Maternity Hospital, Dublin, for two years. In the accompanying table are shown the results obtained. It will be noted that in only one case was blood transfusion necessary after examination and section. All the sections were of the lower segment.

Results of Cases of Placenta Praevia treated by Caesarean Section

Year	Cases	Mothers Lived	Infants		Blood Transfusions	
			S.B.	N.N.D.	Before Examination	After Examination
1944	20	20	0	5	0	0
1945	15	15	0	1	3	1
Total	35	35	0	6	3	1

It will be noted that the method is applicable only in cases in which the cervix has not been taken up. In my experience haemorrhage is not so likely to be provoked by examination in cases in which the cervix is taken up and the canal dilated: the placenta, if present, is usually quickly and easily recognized in such cases. However, in one such case—it was a type II placenta praevia—I did experience a rather sharp haemorrhage, which I successfully controlled in the following manner. I punctured the membranes and introduced two fingers into the uterine cavity inside the membranes; with these fingers I pressed the separated portion of the placenta against the uterine wall, thus controlling the haemorrhage until the baby was delivered section.

Medical Memoranda

Varicella Herpetiformis

Ronaldson and Kelleher (*Brit. J. Child. Dis.*, 1938, 35, 22) are of the opinion that while some cases of herpes zoster are varicellous in nature others are not. They consider that a varicellous case of herpes, being an infective condition which reproduces chickenpox in contacts, is therefore a form of chickenpox, and should not be referred to as "zoster" with or without a qualifying adjective. They suggest the term "varicella herpetiformis" for such eruptions.

Since 1894, when von Bokay first suggested a relationship between herpes zoster and varicella, there have been recorded many instances of chickenpox in one individual following herpes in another, within the ordinary incubation period of the former ailment, with no other source of infection except herpes being discovered. The "dualist" school in the herpes zoster-varicella controversy could maintain that in such instances there is no proof that the subsequent chickenpox case did not acquire the infection from an unrecognized case of chickenpox in the area. The following cases of varicella arising after contact with a case of herpes are considered worth record-

ing because they occurred on an island in Shetland where conditions make it unlikely that any undetected cases of chickenpox could have existed.

Case 1.—In January, 1945, a woman patient was seen with a well-marked herpes on the right side of her chest. Fifteen days later her baby girl developed chickenpox, and three days after this her 5-year-old daughter also developed it. Both were undoubted cases of chickenpox.

Case 2.—In September, 1945, a schoolmistress developed herpes on the right buttock and groin, extending down the thigh. Sixteen days later her 9-year-old nephew, who lived with her, had definite chickenpox. Two weeks later other children attending the school contracted chickenpox.

Most of the inhabitants live on their own crofts and there are no groups of houses which could be called a village. The inhabitants attach an unusual importance to any case of infectious disease. The origin of any outbreak is usually obvious to all, and is often correctly traced to a particular Service man home on leave or to someone who has been elsewhere in Scotland. This can be done in a way that is possible only in an island community with a dispersed population. At the times when the two instances recorded above occurred there were no known cases of chickenpox on the island. There were two other cases of herpes in different areas of the island—one in April and one in June.

Two questions arise: (1) Whence did the cases of varicella herpetiformis acquire their infection? (2) Should every case of "shingles" be individually isolated?

Spontaneous Rupture of the Right Quadriceps Femoris and Left Rectus Femoris in the Same Patient

A railway ticket collector aged 61 made a sudden effort to run after a passenger who had given him the wrong ticket. He stumbled, felt his knees give way, fell to the ground, and was unable to rise without assistance. When seen about three-quarters of an hour after the accident the patient complained of inability to use his right knee, as well as of pain and swelling of the joint.

On examination the right knee could not be extended; the swelling was that of a haemarthrosis and there was a definite gap just above the patella. The left knee could be extended moderately, but a gap was clearly felt at the junction of the middle and lower thirds of the thigh. A distinct bulge could be felt at the proximal end of the gap. X-ray examination of both knees showed marked osteoarthritis. With these findings a provisional diagnosis of spontaneous bilateral rupture of the quadriceps femoris was made.

At operation the right quadriceps femoris was found to be completely avulsed from the anterior border of the patella and there was a marked haemarthrosis. The blood was removed and the quadriceps was sutured to the patella with strong catgut. On the left side the rectus femoris was torn at the junction of the muscle with the tendon of insertion. The ends were approximated with strong catgut, using mattress sutures. Both limbs were placed on back splints, and on his return to the ward the foot of the bed was elevated.

The patient was investigated constitutionally and neurologically, but the results were all negative. The final diagnosis was therefore spontaneous avulsion of the quadriceps femoris on the right side and the rectus femoris on the left.

I wish to thank Mr. N. Cotton, honorary surgeon to the West Kent General Hospital, for permission to publish this case, and to Mr. Alan H. Todd, honorary consultant orthopaedic surgeon to the West Kent General Hospital, for his advice in writing it up.

Cerebral Excitement following Mepacrine Therapy

That mepacrine may produce mental changes has been appreciated for many years, and its effects have been recorded by Allen *et al.* (1937) and Gaskill and Fitz-Hugh (1945). This case is of interest, however, in that it reports three separate attacks in the same individual, and these in some detail.

CASE REPORT

In December, 1945, there was admitted to the Royal Masonic Hospital a temporary serving soldier who was suffering from a frank attack of benign tertian malaria. As a curative measure he was placed on mepacrine, the dosage being 0.7 g. a day for two days and then 0.6 g. a day for seven days. Almost immediately he was seized with a feeling of extreme exhilaration and well-being. He began almost to burst with energy, running instead of walking, and

doing everything at top speed. His mind became choked with ideas, which occurred at all times of the day and night. While many of these never reached maturity, some of them resulted in the patient writing poems and creating new designs for houses and buildings. At times, too, he was seized with an uncontrollable desire to cry, and as a result would weep copiously, although inside he felt, so he said, extremely happy. On one occasion, when asked how he was, he extended his right hand to show the fine tremor which he boasted, and said: "Look, whisky fingers." As a result of these manifestations the patient's past history was gone into in some detail, and the following facts were elicited:

(1) The patient first took mepacrine in February, 1945, while serving in Assam. The dosage was but a small one (one 0.1-g. tablet per day) as the drug was being given as a prophylactic or suppressive measure. Soon after the start of this therapy he began to feel somewhat exhilarated, and his previously lethargic nature became transformed into one of extreme activity. He rose early and drove on with his work, and the days went well. About the same time as this mental metamorphosis occurred he noticed that his skin and urine were intensely yellow, as was the mucus from his nose.

(2) In August, 1945, the patient had his first true attack of malaria, for which he was treated with quinine 10 gr. (0.65 g.) t.d.s. for five days, mepacrine 0.2 g. t.d.s. for five days, and then pamaquin 0.01 g. t.d.s. for five days. During the mepacrine portion of this treatment he experienced all the manifestations of mental stimulation previously described: flights of ideas, poems, artistic designs, window-cleaning, and tears.

(3) Past Health.—This was good, the patient never having suffered from any serious illness.

(4) Family History.—So far as could be ascertained there was no evidence of any psychological disturbance in any branch or root of the patient's family tree. While it was elicited that one of his two sisters tended for a period of her life to be easily worked up, this tendency abated immediately after she had a tumour removed from her uterus, and so there is no real stigma of a psychotic disturbance.

(5) Wassermann Reaction.—This was negative, and so the possibility of lues venerea was eliminated.

After the withdrawal of the mepacrine and receiving phenobarbitone the patient's personality began slowly to revert to its normal state.

My thanks are due to Sir William MacArthur for permission to publish this case.

Injury to the Tonsil

The literature of the last seventy years gives, so far as I could find, only one report (Rohr, 1923) of a tonsillar injury, and therefore the following case was thought to deserve publication.

On Sept. 16, 1945, a boy aged 2½ ran indoors and said he had put a "black thing" into his mouth. His mother, noticing blood in his mouth, brought him to hospital. On examination part of his right tonsil appeared to be injured, with recent blood-clot close to it. The bleeding had stopped; the child was sent home, and the mother was asked to bring him again. When seen the next day the tonsil

Diagram showing injury to tonsil.

had clearly been injured. Part of it was detached and was hanging loosely in his throat. It was considered that it might cause sudden obstruction to the air passages, and tonsillectomy was therefore advised.

At operation, on Sept. 21, the injury was found to be a vertical cut, dividing the right tonsil throughout its upper two-thirds. The anterior pillar of the fauces and the posterior wall showed abrasions. Both tonsils were removed, and the post-operative course was uneventful. The injury was probably caused by a piece of discoloured glass.

Reviews

GENERAL MEDICINE IN 1945

The 1945 Year Book of General Medicine. Edited by George F. Dick, M.D., and others. (Pp. 768; illustrated. 18s.) Chicago: The Year Book Publishers; London: H. K. Lewis and Co.

The Year Book of General Medicine is nearly back to pre-war size with 768 pages; nevertheless it remains a handbook. It is clearly printed and well illustrated, the coloured plate this year being a representation of a skin test for haemochromatosis by means of the prussian-blue reaction. The edition for 1945 contains summaries of articles from the whole field of medicine, and the skill of the editors is shown not only by the conciseness of the writing but by the skilful selection and the pertinent and often critical postscripts. It is probably true to say that few articles written in English which make even the smallest contribution to medical knowledge are missed. Outstanding impressions from the 1945 yearbook are the increasing control of bacterial infections and the persistent failure of the attack on the viruses, leukaemia, and carcinoma. The plasma proteins are being separated into their various components for therapeutic purposes, and the literature of the human blood groups steadily grows in complexity. There is slow but steady progress in the analysis of the haemolytic anaemias. The study of cardiovascular disease is increasingly dominated by the problems of coronary sclerosis and peripheral vascular disease. The editors keep a tight rein on exponents of psychosomatic medicine, though allowing them a good run for their money; and it is perhaps a fair criticism of this popular subject that it does not lend itself to summarization and seems to be an attitude to experience rather than a means to acquiring knowledge. These yearbooks are essential works of reference and they have made themselves indispensable to medical "brains trusters". The index might therefore with advantage be made even fuller than it is at present.

BLOOD TRANSFUSION

Quelques Vérités Premières (ou tout-dit-telles) sur la Transfusion Sanguine. By Arnault Tzanck and Marcel Bessis. (Pp. 66. 80 francs.) Paris: Masson et Cie.

Under the title of "Vérités Premières," which may, in view of the editorial preface, be translated as "accepted facts," Masson et Cie are publishing a series of short medical textbooks written by experts in different fields. The accepted facts are presented in the form of aphorisms in the volume dealing with blood transfusion by Dr. Arnault Tzanck and Dr. Marcel Bessis. In 66 pages the authors cover the blood groups, clinical indications for transfusion, a discussion of the "physiopathology" and treatment of shock, indications for transfusion in surgical and medical conditions, and the technique of blood administration and withdrawal.

Even in a textbook intended for students and practitioners undue simplification and dogmatism are to be deplored, more particularly in fields, like blood transfusion, where research is at present so active. There is no mention of the important developments that have taken place in diluents for stored blood, enabling it to be kept in good condition for 21 days. Sodium citrate is the only diluent advised, and even for this no quantitative figures are given. The whole important problem of Rh is dismissed in 16 aphorisms, with no indication that Rh is a complex agglutinin producing a corresponding number of agglutinins requiring for recognition several different test sera. The use of the sternal route, which during the war has so often proved life-saving, is mentioned as of value in 'exceptional' cases only. The importance of the application of pressure when giving a transfusion in collapsed patients is ignored.

These "accepted facts" on blood transfusion cannot be recommended to English readers.

A HANDBOOK FOR SURGICAL DRESSES

An Introduction to Clinical Surgery. By Charles F. M. Saint, M.D., F.R.C.S., F.R.A.C.S. (Pp. 293. 25s.) Published for the Foreign Press by the African Bookman, 49, St. George's Street, Capetown, S.

One of the great surgical teachers of the last generation, Rutherford Morison of Newcastle, and his pupil Cha now professor of surgery at Capetown, has followed traditions and precepts of his old chief. In *An I*

to *Clinical Surgery*, with the subtitle "Surgical Wherefores and Therefore: A Reasoned Explanation of Surgical Note-taking," he has accumulated the substance of lectures given to students during their dressership. When confronted with a case the student, especially in his earlier days, needs guidance to tell him what to look for, and particularly what the real significance and relative importance of the symptoms and signs he elicits are. In this book he will find what he requires plainly laid out in both general and specific terms, so that if he absorbs the excellent teaching which is provided he will be well on the road to becoming a good diagnostician. The wide experience of the author as a surgeon and teacher enables him to write authoritatively, and his assessment of the relative values of various signs and symptoms displays a wise judgment and discretion. The book is not a textbook, and nothing, of course, is said about treatment, but in our view the author has very handsomely achieved his object of avoiding the "parrot type of acquiring knowledge" and replacing it by "a knowledge based upon and the result of reasoned thinking."

We are not among those who think that a book of this type should be a series of annotated pictures, but nevertheless a few more diagrammatic illustrations would enhance the value of a book which we regard very favourably. The student beginning his surgical studies would be well advised to acquire a copy.

A TEXTBOOK OF DISINFECTION

Disinfection and Sterilization. By Ernest C. McCulloch, D.V.M., Ph.D. Second edition, thoroughly revised. (Pp. 472; 68 engravings. 35s.) London: Henry Kimpton.

This textbook, now in a second edition, contains a vast amount of information which can nowhere else be found between a single pair of covers. Yet those who consult it may or may not find what they seek: the author quotes authorities freely, but by no means all that matter, and his treatment of some subjects is quite inadequate—the acridines, for instance, are dismissed in 23 lines. The author's clinical interests are in veterinary medicine, and he plainly does not understand some of the surgical questions with which he has had to deal (it is a small point, but "filiforms" and "bougies" are separate instruments on p. 270). The chapters describing various classes of chemical disinfectants remain much as they were, except that the synthetic detergents have appeared there; so also have the sulphonamides, though they scarcely qualify for inclusion (in connexion with them an odd misconception is betrayed in the statement, "So great are the specificities of the members of this group of drugs that even the pure powders are not self-sterilizing"). On the other hand, disinfection by steam gets much more thorough treatment: as a guide to the use of the autoclave and other methods of using heat these chapters are excellent. The disinfection of air is considered, as are water purification, sewage treatment, and the "sanitization" of crockery and dairy equipment. Pasteurization and food-canning are major subjects, and, apart from these practical matters, "antibiosis" in general, and the bactericidal action of such things as the digestive fluids, r rays, and supersonic vibrations, are not forgotten.

One would like to see this book expanded into at least three volumes which deal adequately with the various branches of its enormous subject, but even as it stands it will be found a useful source of information on many generally unfamiliar questions of hygiene.

TROPICAL DISEASES

Manson's Tropical Diseases. A Manual of the Diseases of Warm Climates. Edited by Philip H. Manson-Bahr, M.D., F.R.C.P. Twelfth edition. (Pp. 1,068; with 17 colour plates, 9 half-tone plates; 406 figures in the text, 6 maps, and 28 charts. 42s.) London: Cassell and Co. 1945.

A new edition of this well-known manual is an event practitioners are led to expect every five or six years. With each new edition certain improvements have been introduced, so that now the twelfth presents its readers with the greatest amount of reliable information on tropical medicine that it is possible to accommodate in a book of this size. In fact it may be stated with safety that no other book on the subject can compete with it in this respect, so that every medical man whose work lies in the field of tropical medicine can hardly consider himself equipped unless he is armed with the latest issue of *Manson's Tropical Diseases*, which has been so brilliantly edited by Sir Philip Manson-Bahr.

A number of chapters have been fully revised. This applies particularly to those on leprosy and rickettsial diseases, while

much new information has been incorporated in the chapters on malaria and vitamin deficiency diseases. A very useful innovation is the introduction of a table of drugs used in the treatment of tropical diseases, giving their names and synonyms and in many cases their chemical formulae. This will be of great help to the medical man who is continually being confused by the tendency of drug firms to introduce for their own purposes names for already well-named products. A glance at such a list as the one printed here is enough to convince any unbiased person that something should be done to check this unnecessary and bewildering synonymy. There is no need to say anything more about a book that is so well known, but it remains to congratulate the editor on the successful execution of the task which he has imposed on himself for so many years.

Notes on Books

A fourth edition of *A Textbook of Surgery*, by American authors, edited by Dr. FREDERICK CHRISTOPHER, has been published by W. B. Saunders Company at 50s. Since our laudatory notice of this work when first published in 1936 we have commented favourably on each edition as it appeared. The changes in the new edition add to the value of a now well established and widely appreciated account of the practice of surgery. There are two new sections: one on military surgery by Col. E. D. Churchill, lately a surgical consultant to the American Forces in North Africa, and one on chemotherapy by Dr. John S. Lockwood of Yale, who writes on the sulphonamides and penicillin. How up-to-date is this edition may be gauged from the fact that in the excellent article on diseases of the thyroid gland by J. de J. Pemberton and S. F. Haines a well-balanced account is given of the use of the thiourea drugs in thyrotoxicosis. Dr. Christopher is now the leader of a team of over 200 members, many of whose names are surgical household words. There has been a steady increase in the number of contributors and, as might be expected therewith, an increase in size and in the number of illustrations, but the standard is maintained and is a high one, not only in the matter of the text but also in the printing, illustrations, and binding.

Ten volumes of the *Bulletin of the Health Organisation of the League of Nations* have so far appeared, and it has therefore been thought desirable to publish an index. Yet such an index might give a very incomplete picture of the work, since many documents which were issued separately or simply multigraphed would be omitted. The decision has therefore been taken to publish a complete bibliography covering not merely the period during which the *Bulletin* has appeared but the whole of the 25 years of existence of the Health Organization. The present bibliography will be useful to hygienists as a guide to the thousands of technical studies on the most varied subjects carried out under the auspices of the Health Organization of the League of Nations. At the same time it will serve as a record of the work done and as a tribute to the many collaborators from health administrations and scientific institutions throughout the world who have each contributed to that work. It is obtainable, price 6s., from Allen and Unwin Ltd., 40, Museum Street, London, W.C.1.

Dr. AGATHA H. BOWLEY is an experienced psychologist who has studied child life among many different communities and is well fitted to the task by her obvious humanitarian breadth of outlook and real love for children. Her book *The Problems of Family Life: An Environmental Study* (E. and S. Livingstone; 5s., plus 5d. postage), is based on the study of cases encountered during her work at Leicester, and statistical figures are given relating to a variety of factors in a close study of 50 cases. The experienced worker will not find much new in this little work, and no one will dispute the importance of the family environment for the future well-being of the child, but it is simply and pleasantly written so that it can with confidence be recommended for study by those who are less well instructed. Normality and abnormality in family life are both dealt with, as are relationships between teachers and parents. The infectiousness of anxiety, the establishment of bad habits in the home, and the aggressive reactions to emotional stress are explained sympathetically. Among the appendices is a useful list of suitable play material for different ages. Within its limited scope doctors, parents, and teachers will find this book a good companion, easily read, pleasantly illustrated, and clearly expressed.

The U.S. Information Service, 33, Davies Street, London, W.1, reports that the National Research Council of the U.S. Government has prepared a comprehensive index of scientific, medical, and technical books published in the United States from 1930 to 1944. Five thousand copies of the volume are being distributed to United States embassies, legations, and libraries throughout the world. All the books listed are in print and are available for distribution by the United States International Book Association, New York.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MAY 18 1946

THE SPENS REPORT

The Spens Committee, whose report is abridged in this week's *Supplement*, was appointed in February, 1945, under the following terms of reference

'To consider, after obtaining whatever information and evidence it thinks fit, what ought to be the range of total professional income of a registered medical practitioner in any publicly organized service of general medical practice, to consider this with due regard to what have been the normal financial expectations of general medical practice in the past, and to the desirability of maintaining in the future the proper social and economic status of general medical practice and its power to attract a suitable type of recruit to the profession, and to make recommendations'

Of its nine members, eight put their names to the recommendations, while the ninth, Sir Ernest Fass, added a rider of his own. The majority recommendation is that approximately half of all general practitioners between the ages of 40 and 50 should receive annual net incomes of £1,300 or more, that about three-quarters of practitioners should receive net incomes over £1,000, that about a quarter should receive over £1,600, that slightly less than 10% should receive over £2,000, and that in a small proportion of cases it should be possible for general practitioners to obtain net incomes of at least £2,500. By net income is meant gross income less professional expenses allowed by Inland Revenue for income tax purposes. These recommendations are made in terms of the 1939 value of money, and it is to this value that all the figures and recommendations in the report refer. The Committee has also assumed that the practitioners will have to provide for themselves by insurance against early death, old age, and illness.

These recommendations mean an increase on 1939 net incomes by £200 a year for incomes between £400 and £1,200, and above this by £200, diminishing progressively to nothing at £2,000. The Committee also recommends that "before 40 and after 50 practitioners should be remunerated at the rate applicable between 40 and 50 to the burden and responsibilities of practice which they are in fact carrying." There should be a reduction of the difference between incomes of rural and urban practitioners, and remuneration under the Highlands and Islands scheme should be increased, the scheme to be applied to other sparsely populated areas. In areas which do not attract an adequate supply of practitioners additional remuneration should be offered. In practices where there is an abnormal number of aged persons and chronic invalids some adjustment in the method of payment is advised in so far as this depends on capitation. Finally it is recommended that a recently qualified practitioner on completing resident hospital appointments should obtain an initial net income of not less than £500 a year as an assistant in general practice. In this connexion the Committee suggests that about 10% of practitioners should be selected as

specially suitable to train young men entering general practice as assistants after completing house appointments. A supervision fee of £100 a year in respect of such an assistant is suggested. The approved practitioner will have to provide the assistant's £500 in his first year and £600 in his second, and expenses on top of this. As it would take time to enlarge a practice to an extent which would cover this expenditure, it is suggested that the approved practitioner "who has not previously had an assistant should receive as well as the supervision fee £500 in the first year £300 in the second, and £100 in the third year in which he had assistants." Again it should be emphasized that the Committee's recommendations are in terms of the 1939 value of money. "We leave to others," the Committee observes, "the problem of the necessary adjustment to present conditions, but we would observe in this connexion that such adjustment should have direct regard not only to estimates of the change in value of money but to the increases which have in fact taken place since 1939 in incomes in other professions."

The Committee sets forth in a table the net incomes of general practitioners in urban areas in the years 1936-7-8. This table shows that throughout the best years of a G.P.'s working life—between 40 and 55—almost 20% of urban practitioners had a net income of under £700 a year, and that over 40% had a net income of under £1,000. The Committee was unanimous that these percentages are too high, having regard to the length of training. It points out that in relation to other professions the doctor has a long training and a hard life. In 1931, for example, the mortality among doctors between the ages of 20 and 65 was 54% above that of higher civil servants and 26% above that of professional engineers. The Committee is clear that the proportion of practitioners able to reach an income of £1,300 or over is too low. Apart from any proposals for a publicly organized general medical service, it considers that unless conditions are substantially improved the social and economic status and the recruitment of general practitioners cannot in the long run be maintained. It points out that many young doctors in the past have been deterred from specialist practice by the risks and by the certainty of a number of lean years. As these deterrents will be less formidable in the future, there will be increased competition between other forms of medical practice and general practice. "We," the Committee states, "and not least our lay members, consider that it would be disastrous to the profession and to the public if general practitioners were recruited only from the less able young doctors." If, therefore, general practice is not made financially more attractive the majority of the able will seek to become specialists. Another point the Committee makes is that financial worry must inevitably prejudice the efficiency of many general practitioners. For practitioners in the age group 40-49 the Committee's recommendations can be summed up by saying that there would be only 7% receiving a net income of under £700 per annum, as against 20% before 1939, 24% receiving £1,300 to £1,600, as against 17.5%, and 16% between £1,600 and £2,000 as against 10%.

The Committee was satisfied that "there is a far greater diversity of ability and effort among general practitioners

than admits of remuneration by some single scale applicable to all." Therefore there must be a differentiation depending on ability and effort. "We are satisfied by the evidence put before us that no existing degree or qualification can usefully be made the basis of additional payment, largely because many of the qualities which make the best general practitioner are, in fact, unexaminable." Although it is not in the Committee's terms to express an opinion on the method of remuneration, it does observe that "capitation offers a method of differentiation which is acceptable to the majority of the profession." If the number of persons in a publicly organized service is 45,000,000 the Committee's proposals could be realized at the cost of 15s. 6d. per head.

The Committee feels it should justify its figures, because they are a considerable increase on the capitation payments under the N.H.I. scheme, and on the total net income of practitioners in the three years ending 1939. But the Committee was told it should not be bound to accept as satisfactory the capitation and mileage payments which existed before 1939, and that it could consider rates of remuneration *de novo*. The Committee found justified the widespread feeling among doctors that capitation and mileage payments have been too low. Evidence showed that in the case of mixed panel and private practice "the proportion of the time spent on panel patients to that spent on private patients was in general greatly in excess of the proportion of income derived from panel patients to that derived from private practice." Many witnesses stated that two-thirds of their time was spent in looking after panel patients, even though they contributed only one-third of their total income. The Committee also believes that it will not be possible to maintain recruitment in a profession with such heavy responsibilities if so high a proportion of middle-aged doctors are earning the low incomes of 1939 and before. The Committee also observes that there will be much increase of work in a publicly organized service in which the doctor is not paid per visit. It believes that it is important to improve prospects in general practice as to make it attractive enough to prevent all the abler "from trying to enter specialist practice."

PROGRESS IN THE TREATMENT OF SYPHILIS

It is a serious criticism of the treatment of syphilis by weekly injections of neoarsphenamine that a large proportion of the patients do not complete the course, remain infected, and are a source of danger to the community. In America, where syphilis appears to be a greater problem than it is here, steps have been taken to try other methods; and, indeed, a spirit of enterprise has been displayed which has resulted in commendable progress. It is true that American enthusiasm leads to the trial of measures some of which take our breath away, but their greater grasp of the principles of drug action and the experience they gain from their trials result in notable advances.

The recent activity may be said to have begun in 1931, when Hirschfeld, Hyman, and Wanger¹ demonstrated what seems an obvious point—that the toxicity of many sub-

stances given intravenously depends on the rate at which they are put in. They spoke of "speed shock." This led to a proposal by Chargin in 1932 that neoarsphenamine should be given in syphilis by intravenous drip. In 1935 Chargin, Leifer, and Hyman² published 25 cases, and by 1940 there were³ 400. These were given treatment daily for 5 days, the first 111 patients receiving neoarsphenamine, those coming after being given mapharsen, or, as we now call it, mapharside. The damage in the first group was serious; in 43 there was evidence of peripheral neuritis, and one patient died from haemorrhagic encephalitis. In those receiving mapharside, however, the outcome was much better. Even in 1945 an observer as experienced as Earle Moore⁴ said that the success of the 5-day method is about as great as that attained with the usual 12–18 months' treatment in those patients who complete the long treatment, of whom about 80–85% are cured. From the point of view of the community this is a great advance, since all complete the 5-day course. From the point of view of the individual, however, the result is less good; he is exposed to a death risk of 1 in 400, as compared with a risk of 1 in 15,000 by the longer treatment.⁵ In the 1940 discussion³ on the 5-day method Earle Moore suggested that a series of single injections given, for example, in 3 weeks might be as efficacious and less dangerous.

The Americans therefore turned to the laboratory workers. Eagle and Hogan⁶ began an investigation of syphilis in rabbits. They compared the effect of twelve different treatments with mapharside, varying from the use of intravenous drip for 6 hours on one day to weekly injections for six weeks. They found that the total curative dose of mapharside was constant irrespective of the period over which the treatment was given. Whether the interval between injections varied from 2 hours to 1 week, and whether the total number was 1 or 16, the curative dose remained between 4 and 8 mg. per kg. But as the duration of treatment increased, so the maximum tolerated dose increased, and therefore the margin of safety rose. Then there was the spectacle, unusual in this country, of the laboratory workers telling the clinicians how to plan their treatment, and the clinicians in the main following their advice. Eagle and Hogan considered that any desired margin of safety could be attained by prolonging the period of treatment, and that what was needed was a compromise between an 18-month course which was "vexatious" and a 5-day course which was "dangerous." On their proposals a clinical investigation was begun, the results of which were described by Eagle.⁶ The chief conclusion was that three injections per week of mapharside, each 40–60 mg. when given for 9–12 weeks, cured 82% of cases of early syphilis. Out of 4,823 patients 106 did not complete the treatment because of toxic effects, among which were 2 cases of encephalopathy. In the meantime, between April, 1943, and January, 1944, an intensive treatment of syphilis was begun in the U.S. Army in Europe, in which 775 patients received (Pillsbury *et al.*⁷) a 20-day

¹ *Arch. Int. med.*, 1931, 47, 259

treatment in which mapharside was given in a dose of 1 mg. per kg. daily, together with 8 doses of bismuth salicylate. Of the 775 patients 746 completed the treatment, the others discontinuing because of reactions, of which fever in the second week was commonest. At the present time in the U.S.A., when treatment of early syphilis is carried out by organic arsenicals, mapharside is the substance for the most part used, and it is given either three times weekly for 9-12 weeks, or daily for 20 days. The use of neoarsphenamine has been discontinued. Confusion respecting the relative value of mapharside and neoarsphenamine has arisen in this country because some do not understand that mapharside is excreted in 2 days whereas neoarsphenamine takes from 5 to 7 days. Thus if only one injection is given per week it follows that neoarsphenamine is superior to mapharside, but if injections are given three times weekly mapharside is said by very high authority to be much superior to neoarsphenamine. This can readily be understood when it is realized that 60 mg. mapharside is the equivalent of 600 mg. neoarsphenamine.

Not only in the treatment of early syphilis has knowledge been furthered: the relative value of malarial therapy and of artificial fever for neurosyphilis has been explored. In 1940 a committee reported³ on 1,100 parietic patients treated with malaria and on 320 treated with artificial fever. The results showed that about half the mild cases had remissions, whether they were treated with malaria or with artificial fever. Of severe cases, however, only 1% had remissions after malarial therapy, while 11% had remissions after artificial fever. Attempts have also been made to apply a combination of mapharside and artificial fever to patients with neurosyphilis (Simpson, Kendell, and Rose⁴) and also to patients with early syphilis, the crowning effort being a treatment intended to effect a cure in one day. This consisted in an initial dose of bismuth salicylate (0.25 g.) and then a 10-hour period of artificial fever at 106° F. (41° C.) (rectal temperature). During the first 7 hours of the fever 0.24 g. mapharside was given by intravenous drip. None of these attempts has been rewarded by much success.

In view of this offensive spirit it is not very surprising that it was the Americans who first discovered the value of penicillin in syphilis. Mahoney, Arnold, and Harris¹⁰ reported in 1943, and again in 1944; and later in the same year Moore, Mahoney, *et al.*¹¹ described results in 1,418 cases. To have secured observations on so many in so short a time represents a considerable achievement; it is in striking contrast with the poverty of the data recorded in papers from this country. High hopes were obviously placed on the excellent clinical results which penicillin quickly gave; as time has gone on expectations have diminished, and it is now certain that a combination of penicillin and mapharside is much more effective in preventing early relapses than is penicillin alone. From their observations in rabbit syphilis Selbie and Simon¹² reached the conclusion that a short course of penicillin is as good as a single dose of an arsenic compound, but that much more penicillin than arsenic is needed to produce a permanent effect, because of the more rapid excretion of the penicillin. Lloyd Jones and Mait-

land,¹³ and more recently Lourie *et al.*,¹⁴ have done good service by pointing out that penicillin treatment of syphilis must be organized so as not to require the patient to come into hospital. In the last paper the size of the penicillin dose had risen to 600,000 units given three times daily at hourly intervals for 5 days. We can see that the final place of penicillin in syphilis is not yet known, but it is likely to be the Americans who will find it.

CHEMICAL CONSTITUTION OF PALUDRINE

The discovery of paludrine (M. 4888) by Rose, Curd, and Davey¹⁵ has already been recorded in this *Journal*; a description of its evolution and of the initial experimental and clinical investigations has now been published.¹⁶ Paludrine is N_1 -*p*-chlorophenyl- N_2 -isopropyl biguanide,

a chemical type not hitherto met with in chemotherapy. It owes its origin to a chain of thought which began with the earlier synthetic drugs. The molecule of paludrine reveals a benzene ring linked to an isopropylamino group

joined "in series." A characteristic of the amidine group is its capacity to be involved in resonance—that is, for electrons to move from one nitrogen atom to the other and back again, with a consequent displacement of electrical charge and the appropriate shift of the double bond, thus:

Paludrine has certain chemical features in common with mepacrine. Both are strong bases and form stable salts

with acids; both contain a chlorine substituted benzene ring, and both carry alkyl groups attached to nitrogen (that in mepacrine being more complex). Mepacrine also has a resonance system across the middle of the molecule; not the simple amidine group that appears twice in paludrine, but an extended amidine system with an unsaturated carbon

chain ($\text{—C}=\text{C—}$) interposed, which still permits the drift of electrons from one nitrogen atom to the other, thus:

The biological significance of such a resonance is not apparent, although it is known to influence physical properties.

³ *J. Amer. med. Ass.*, 1940, 115, 677.

⁴ *Brit. J. vener. Dis.*, 1941, 17, 1.

¹⁰ *J. Amer. med. Ass.*, 1944, 126, 63.

¹¹ *Ibid.*, 1944, 126, 67.

¹² *Brit. J. exp. Path.*, 1944, 25, 229.

¹³ *Brit. J. vener. Dis.*, 1945, 21, 65.

¹⁴ *Lancet*, 1945, 2, 696.

¹⁵ *British Medical Journal*, 1945, 2, 653.

¹⁶ *Ann. trop. Med. Parasitol.*, 1945, 39, 139.

The evolution of paludrine was not as direct as this comparison of paludrine and mepacrine might imply. The first substance of the new series found active in experimental malarias was 2666. This contained the substituted benzene ring and the alkyl

group attached to a nitrogen atom, and close inspection shows both extended, and true amidine systems. The pyrimidine ring was selected for chemical study because it provided these resonance features, and because, unlike the acridine nucleus of mepacrine, it did not normally give rise to coloured derivatives. Pyrimidine was also a "vital" ring structure, occurring in a number of important biological systems, and in view of its value in the sulphanyl-amide series (sulphadiazine, sulphamezathine) its use in antimalarial synthesis was timely. The compound 3349, which was a guanidine derivative of 2666, and even richer in amidine groups, was more active in experimental malarias, and was the first of the new type to show an action in human malaria. The most profitable lead from extensive research on these structures, during which more than a thousand compounds were made, came from an attempt to simplify the 2666 molecule by assuming a minimal structural requirement for antimalarial activity and omitting superfluous chemical detail. The fragment postulated as inessential is that shown within the dotted lines in the 2666 formula. The residue was then seen to resemble the arrangement of atoms found in the biguanide molecule ($\text{NH}_2-\text{C}(\text{NH})=\text{N}-\text{C}(\text{NH})=\text{N}-\text{NH}_2$); the corresponding

biguanide derivative was accordingly synthesized. After many more preparations highest activity was ultimately found in paludrine, in which the terminal alkyl group was simple isopropyl, in place of the more complex diethylaminoethyl group in the 2666 molecule.

INHERITED POLYPOSIS OF THE COLON

Since Luschka¹ in 1861 observed in the post-mortem room some thousands of polypoid tumours thronging the colonic mucosa of a woman aged 30, this rather uncommon and peculiar pathological echo of genetic mutation has fascinated three generations of clinicians. The pathology of inherited polyposis is well understood. In an affected colon every stage of polyp formation can be recognized, from the initial heaping and overgrowth of mucosa and multiplication of its glands, to the final tumours, pedunculated or cylindrical cystic with dilated glands. Ultimately carcinoma develops at the neck of one of these adenomas, where the cells are distorted, crushed, stunted, and ill nourished, giving the precancerous appearance which Cuthbert Dukes² has styled "collar catarrh." Barger and

Coffey³ record the development of carcinoma of the colon in 82.8% of those who inherit polyposis.

The genetic peculiarities of the condition are also well documented. Polyposis is inherited as a Mendelian dominant. In most affected families it is found in every successive generation. As a rule those who transmit the disease suffer from it, though Bernstein⁴ has recorded a family in which the disease skipped a generation. Polyposis may be transmitted by either sex to either sex, but its incidence is rather higher in males than in females. A curious feature of polyposis is that, though inherited, it seems never to be present at birth, in this respect resembling hereditary optic atrophy and certain forms of hereditary degeneration of the macula. The disease has been recorded in a child of 2 years (McKenney⁵), but in most cases the onset is delayed until the late teens or early twenties. That this curious delay is due not merely to a postponement of symptoms but to a real lag in the actual development of polypi was clearly shown by Lockhart-Mummery,⁶ who, performing pre-cautionary sigmoidoscopy on a member of an affected family at the age of 39, found him free from polypi, but repeating the examination four years later, observed that polyposis had become well established in the interval.

The treatment of polyposis is now fairly standardized. Pfeiffer and Simmons Patterson,⁷ and most other recent authors, advocate a combination of fulguration and colectomy. They eradicate polypi from rectum and rectosigmoid by trans-anal fulguration, short-circuit the colon by an anastomosis of ileum to rectosigmoid, and then proceed to remove the large bowel from caecum to lower sigmoid. The initial fulguration of the accessible lower colon is done in multiple stages, with an interval of not less than three days between sessions. Fulguration is not entirely without risk, for perforation and haemorrhage may occur 5 to 10 days after the operation. It is also not free from discomfort to the patient, and Buie even advises that colectomy precede fulguration, so that if the operation prove fatal the patient has at least been spared the inconvenience of fulguration.

The acquired form of polyposis of the colon, which develops in 10.16% (Rankin,⁸ Barger and Coffey⁹) of cases of chronic ulcerative colitis, differs in certain pathological respects from the inherited variety. Acquired polypi tend to be limited to quite short stretches of colon—Barger and Coffey found them disseminated throughout the whole colon in only 16.6%; they are less numerous and more varied in size and shape than inherited polypi, and in only 21.9% of cases do they proceed to carcinoma.

DELAY IN PUBLICATION OF SPECIAL JOURNALS

Subscribers have had cause to complain of the delay in publication of some of the quarterly journals published by the B.M.A., and we take this opportunity to offer an apology and an explanation. Difficulties in the paper and printing trades seem to have been more acute during the past six months than at any time before the war. One of the difficulties has been to secure delivery of the paper from the mills to the printer. And in instances in which the text paper has been delivered, publication has been held up because of the absence of cover paper. These obstacles are of no one's making, but inevitably accompany the transition from war to peace. Subscribers will eventually get their full number of issues.

WHAT THE RUSSIANS EAT

BY

LYDIA TEHILY, M.D.

For the last few years the English press has re-echoed with the extraordinary exploits of Russian soldiers, and of the Russian people in general—exploits often carried out in a temperature of 45° below zero. Knowing the vast expanse of Russia, the appalling condition of the roads and the lack of transport one is inclined to ask: 'What do the Russians eat that they should possess such extraordinary stamina and resistance to infection?'

Whole-grain Cereals as Staple Foods

The staple foods of the Russians are whole grain rye and wheat bread and whole grain buckwheat—the latter used for many purposes. The whole grain bread is almost black and is rather coarse, but Russians like it, indeed they prefer it to white bread, which they say tastes "like cotton wool." Unlike other staple foods—such as white bread, maize, or polished rice—black bread even if consumed in large quantities does not produce any vitamin deficiency diseases. When preparing to advance as regular food supplies could not always be relied on, Russian soldiers invariably took with them their "iron ration"—chunks of black bread—to sustain them for two or three days.

In spite of German requisitioning, and the 'scorched earth' policy one may be quite sure that Russian peasants hid quantities of grain—an art in which they are adept owing to past bitter experiences. Actually Russians can live on a diet of black bread alone for weeks and months, and if this diet is supplemented by berries (Russian forests are rich in these), and occasionally by milk and milk products they can exist indefinitely. Buckwheat, also a whole grain cereal, is used as a main dish (gruel), as a supplement to meat, as a dessert (eaten with milk or cream), to stuff poultry or meats or to fill pies.

Animal Protein derived mainly from Milk and Milk Products

Milk and milk products play a great part in the diet of Russians so a peasant feels secure from famine only if he possesses a cow. Even in the Soviet Republics the authorities have had to depart in this instance from the idea of communal ownership and to allow each family to have a cow as private property. The war news reels from the U.S.S.R. often show the pathetic sight of peasants fleeing from their burning villages, the women dragging the children with one hand and leading with the other their so-called "nourisher," the cow. The guerillas, also, while living in makeshift huts in the woods usually have a few cows tethered near by. Thus even under difficult conditions milk and milk products are made available. Although meat or fish is usually eaten with every meal, the first-class protein is derived mainly from the milk and milk products. Sour milk and sour cream are eaten in large quantities in addition to fresh milk, cream, butter, and cream cheese. Sour milk is indeed often preferred to fresh, and is eaten plain or with sugar, and is considered to be good for the digestion and also to be the best remedy for a "hang over." Cream cheese is eaten as a dessert (mixed with milk or cream and sugar), made into pancakes, or used as a filling for pastries, patties, and cakes.

Sources of Vitamins and Minerals

Undoubtedly, in Russia milk and milk products are also the main source of vitamins A and D. Before the Revolution vitamin A deficiency in the form of xerophthalmia was mainly encountered in persons who undertook repeated and prolonged fasts, during which they abstained from milk and milk products in accordance with the practice of the Greek Orthodox religion. During Lent, too, infants fed by women deficient in vitamin A often went blind as a result of keratomalacia. Therefore one may presume that vitamin A deficiency might still be found among people of the "old regime."

It is surprising that in a country where the greater part of the year is very cold, and where the children, if outdoors, are so muffled up that only the eyes are visible, rickets is uncommon. In general the bone formation of Russians is good, while white strong teeth are a national characteristic.

Vitamin B is mainly supplied by black bread and buckwheat, while an additional supply is sometimes derived from a home made slightly fermented drink (kvass) made of stale bread, yeast, and sugar. At any rate, the deficiency of this vitamin has never been observed in Russia. Even during the sieges of Leningrad and Stalingrad, when hundreds of thousands died of starvation, the deficiency of vitamin B was not noted. This was in marked contrast to Spain, where the staple food is white bread and polished rice, and where a great number of cases of nervous and mental disorders occurred during the Civil War.

As a result of the long winters fresh fruit and vegetables are available only for a short time, and their storage also presents a problem owing to the extreme cold. In spite of this scarcity is uncommon. In winter the Russians live mainly on dried, salted, pickled, and otherwise preserved fruit and vegetables, the commonest being salted cabbage. Cabbage was the favourite vegetable in Russia long before its good vitamin C content was known to science. It as well as other vegetables, is usually cooked so that no vitamins or minerals are wasted—i.e., either they are eaten with the water in which they were boiled (e.g., soup), or they are fried, braised, or stewed. In addition frozen cranberries are sent from Leningrad in the north to most parts of Russia, and their juice, which is fairly rich in vitamin C, is widely used as jellies.

The national drink of Russians, apart from vodka, is tea. Before the antiscorbutic properties of lemons were known the Russians drank their tea with lemon. As large quantities of tea are drunk in Russia, especially among the intellectuals, the amount of lemon consumed each day must be considerable. Admittedly since the beginning of the recent war the importation of lemons from abroad has ceased but certain quantities of home grown lemons are still available. Besides, when supplies were short or during sieges, as an anti-scorbutic measure Russians took to drinking infusions made from fir and pine needles.

Thanks to the method of preparing vegetables and to the use of whole grain cereals and milk products, there is no deficiency of calcium or other minerals.

Large Calorie Requirements

The Russian soldiers, in addition to tea and bread in the morning get their traditional diet of cabbage soup, soup meat, buckwheat gruel, and black bread twice daily. Although the main ingredient of cabbage soup is cabbage (fresh in summer and salted in winter) all available vegetables can be added to it, but those most frequently used are beetroot, potatoes and tomatoes (or tomato juice). As a rule, in normal times, a Russian soldier received 3,200 calories a day, not including bread, which was unrestricted and of which an average of 1 kg per person was consumed daily. However, since the beginning of the Second World War bread was rationed and distributed according to the importance of work, a maximum of 900 g being accorded to soldiers and heavy armament workers. As can be seen, the calorie requirements of Russians are great, owing undoubtedly to the rigorous climate. In consequence they take everything with a good deal of fat, and raw bacon is often eaten with black bread. For cooking purposes sunflower seed oil is widely used, so that sunflowers which are grown in almost every garden in Russia, are not only ornamental but useful. Even the cracking of sunflower seeds, a widely indulged in pastime, may be the response of the body to the physiological fat requirements.

Conclusion

Thus from either instinct or experience, the Russians have chosen the most wholesome cereals, and they prepare their food in a way which conserves both vitamins and minerals as much as possible. Taking into consideration the economic and climatic conditions, it would seem that alterations in the food habits of Russians are neither necessary nor desirable. Indeed, it has been stated that the black bread of Russians has won the war for them. Although this statement is rather an exaggeration one has to admit that the black bread helped considerably.

Of course the food referred to in this article is that consumed by the masses of Central European Russia. The populations of the extreme north and south, as well as Russian Asiatic races have their own food habits, more suitable to their climates and their own agricultural products. Hotels and restaurants de luxe, as well as the more privileged people, use normally a modified French "cuisine," with the addition of some national dishes, such as the ubiquitous caviare.

While the King's Fund considers that the responsibility for proper provision in case of fire rests with hospital committees it is thought that notes on the prevention of fire on the lines of those first prepared for the Fund in 1907 and revised in 1926 would be of service to hospital committees in deciding whether the fire precautions at individual hospitals are adequate. A new and revised edition has now been prepared after consultation with the chief regional fire officer for the London Region of the N.F.S. The recommendations relate to the prevention of fire due to various causes, restriction of spread, access for fire fighting purposes, fire exits, fire appliances, fire drills, method of giving the alarm and other immediate steps to be taken. The memorandum is published for King Edward's Hospital Fund for London by George Barber and Son, 23, Fumival Street, E.C.4, price 6d post free.

MORE HOSPITAL SURVEYS

SOUTH-WEST ENGLAND; SOUTH MIDLANDS;
EAST ANGLIA

The hospital services of a wide belt of Southern England, from Devon and Cornwall to the eastern counties, are the subject of three more volumes of the Hospital Survey initiated by the Ministry of Health.¹ The surveyors in the south-west area were Mr. Zachary Cope, Dr. W. J. Gill, Mr. Arthur Griffiths, and Dr. G. C. Kelly; in the Berkshire, Buckinghamshire, and Oxfordshire area, Mr. E. C. Bevers, Prof. G. E. Gask, and Prof. R. H. Parry; and in the eastern area Sir William G. Savage, Sir Claude Frankau, and Sir Basil Gibson.

BRISTOL AND THE SOUTH-WEST

The south-western area comprises the counties of Gloucestershire, Somerset, Wiltshire, Devon, and Cornwall, and the surveyors consider that the whole region should be treated as one. The regional hospital centre, the clinical capital of the service, the seat of medical training, both undergraduate and postgraduate, and the main centre of nursing training, will obviously be at Bristol. The central hospital unit at Bristol should be placed on a site ample for future development. This will mean ultimately the abandonment of the present General Hospital and the conversion of the Royal Infirmary into a casualty reception station and an auxiliary out-patient department. New hospital buildings, including a general hospital of 800 beds, a maternity hospital of 100, a children's hospital of 200, another hospital of 200 for aged and chronic cases, possibly a sanatorium accommodating 200, and possibly also the medical school, should be placed together away from the congested part of the city. A site to the south of the River Avon is tentatively suggested. It is hoped that the Royal Infirmary will find it possible to provide the area general hospital, that the Bristol Maternity Hospital will administer the new maternity centre, and that the Hospital for Sick Children will undertake the provision of the new children's hospital. Southmead Hospital, belonging to the Bristol Corporation, should be developed as a district hospital, and suggestions are made for two other district hospitals in Bristol, and others at Weston-super-Mare, Taunton, and Yeovil, and for 11 local hospitals in the Bristol area. District hospitals are defined as hospitals to be staffed and equipped to undertake a considerable range of medical and surgical practice, while the local hospitals will be available for post-operative care of cases, and for patients who, had the home conditions been reasonably satisfactory, the general practitioner would normally have treated at home. It is considered that Bristol and Taunton should be the only centres for hospitals for infectious diseases.

In Gloucestershire a scheme for an area hospital centre has already been put forward, on a site not yet selected, between Gloucester and Cheltenham, the Royal Infirmary at Gloucester and the General Hospital at Cheltenham to serve as out-patient centres, casualty reception stations, and local hospitals. In this area there is not considered to be any need for district hospitals; seven local hospitals are placed. In the Bath area the organization of a hospital centre on the Combe Park site is recommended to serve the Somerset districts already depending on Bath hospitals and all districts in Wiltshire, with district hospitals at Swindon and Salisbury and maternity centres and isolation hospitals at those two towns and in Bath itself.

For the Exeter area it is recommended that the Royal Devon and Exeter Hospital be developed to become an area hospital, with Exeter City Hospital associated for the care of incurable cases. District hospitals should be at Torquay and Barnstaple, and 16 affiliated local hospitals are suggested. Geographical considerations suggest the closing of seven other small hospitals, but it is admitted that there may be local reasons why some of them should be retained; others might conveniently become health centres. In Plymouth the best course is considered to be the development of a hospital centre with a general hospital and associated institutions all on one site. No district hospitals are thought to be needed in this area, but four local hospitals are recommended. Two alternatives are possible in West Cornwall—one that the whole of

Cornwall should be included in the Plymouth area, the other that West Cornwall should form a separate area with its own centre. The surveyors favour the second course. It is recommended that a new site for a hospital centre should be found in or near Truro, and on it a general hospital of about 400 beds should be built together with special hospitals. The consulting staffs of the Royal Cornwall Infirmary and the Camborne-Redruth Miners and General Hospital should combine to form the specialist staff. A district hospital should be established at Penzance and another on the eastern side of St. Austell, and nine local hospitals are marked out.

Some General Comments

The surveyors of the South-Western Area have some interesting general comments to make. They were struck by the manner in which the affairs of small voluntary hospitals are controlled in varying degrees by committees, medical staffs, and matrons.

"The inclinations and enthusiasms of the medical staffs may determine the functions of a small hospital. To refer to one example, a small hospital was opened a few years ago. One of the general practitioners in the neighbourhood was interested in obstetrics, and as a result of the needs of his patients the hospital became a maternity home. A few years later he left the district. His successor had an interest in general surgery. The maternity practice was stopped, and the hospital became filled with surgical cases. As regards one or two small hospitals it would not be incorrect to say that they had become private nursing homes supported by voluntary contributions."

Too few specialists practise in this area. The surveyors were constantly reminded of the inadequate numbers of obstetricians and gynaecologists and the difficulty of getting the help of a dermatologist. Orthopaedic surgery requires to be developed, especially in Gloucestershire. No uniform scheme of appointment of medical staffs was apparent. The committees of some hospitals appoint all medical practitioners in the locality; in others hospital appointments are in the hands of practitioners already on the staff, and it is in their power to "blackmail" any newcomer, however well qualified. In the larger hospitals the appointment of the members of the visiting medical staffs is subject to an age limit, but in the smaller hospitals the medical staffs may continue to do clinical work until they retire from medical practice. One general practitioner undertook major surgical operations until he was 80. General practitioners often defer calling in consultant help because no fees can be offered, so that patients in a general ward may have to wait for a consultant opinion until a private patient also requires the advice of a consultant in that branch. Yet there is no reluctance on the part of consultants to give their advice and operative skill without fee.

Public assistance institutions were found in which no trained nurses were employed. "Nevertheless we were impressed by the sympathy and evidence of sustained solicitude which matrons, sisters, and nurses showed towards the patients in their care." The majority of public assistance institutions have so many defects as to be unsuitable for further use for aged and chronic sick, who should be reclassified and redistributed, some of them in special units at selected local hospitals.

In the surveyors' view all the consultants should be wholly engaged in consulting work, but for several years to come it will be necessary to accept a less rigid system in certain areas. During the interim the term "consultant" should apply to the member of the visiting staff of a large general or special hospital who is recognized by his professional colleagues as a specialist in general medicine or surgery or in some branch, whether or not he is engaged in general practice.

The desire has been expressed that a medical school should be organized in connexion with University College, Exeter, or in Plymouth; but while such a scheme may be possible in future years, for the present it is considered a primary duty to see that the medical school at Bristol University is fully staffed and equipped.

OXFORD AND ITS AREA

The survey of the hospital services of Berkshire, Buckinghamshire, and Oxfordshire is illustrated by many maps and plans for an ampler provision and better distribution of hospital beds. It is considered that the hospital services for this area should be planned to meet the immediate needs of a popula-

¹ London: H.M. Stationery Office, 1945. *Hospital Survey: South-Western Area*, 10s. net; *Berkshire, Buckinghamshire, and Oxfordshire*, 5s. net; *Eastern Area*, 2s. 6d. net.

tion of about 1,000,000—the population in 1938 was estimated at 867,000—and for this purpose a total of 9,970 beds will be needed, of which 5,000 should be for acute cases and 2,500 for chronic, 600 for maternity, 1,000 for tuberculosis, and 800 for infectious diseases. The present number of beds in the area is 5,711. The greatest deficiency is in Buckinghamshire (1,782). There is also a shortage of medical personnel, most obviously in the consultant-specialist class.

Among the general recommendations of the surveyors are the following: Fever hospitals should be called upon to deal not only with "notifiable diseases" but with such forms of acute infections as most require hospital treatment. The bulk of the public assistance institutions inspected are so bad and ill adapted for their duties that a new service in modern buildings is necessary. Children in these institutions should be separated from adults and cared for in a different environment. Chronic sick should be housed in separate blocks within the curtilage of the general hospital. Colonies under the charge of the health authority should be provided for the aged and infirm. Recommendations are also made for the better organization of out-patient departments—including an appointments system—for the provision of after-care homes for patients requiring post-hospital care or convalescence, and for many improvements in specialist services.

Health Centres Advocated

The policy of establishing health centres as the basis of the health and hospital services of the area is warmly approved by these surveyors. They recommend that existing cottage hospitals should be developed as health centres for their districts, and that other health centres should be established at Hungerford and Wokingham in Berkshire, Beaconsfield, Bletchley, Newport Pagnell, Princes Risborough, and Wolverton in Buckinghamshire, and Witney and Woodstock in Oxfordshire.

The problem of Oxford is declared to be peculiar and weighty. The city and the parts around it rely for their medical services on the Radcliffe Infirmary, which old voluntary hospital is unable to meet the growing demands. Two courses are open: one to reconstruct the Radcliffe Infirmary on its present site and build a second hospital somewhere else, and the other to evacuate the present Radcliffe site and build a new hospital of 1,000 beds about two miles from the centre of the city. In the view of the surveyors the advantages of the second of these plans are overwhelming, but in order to make it effective close co-operation between the municipal authority and the voluntary hospital will be necessary.

It is considered that Aylesbury, the county town of Buckinghamshire, should take a more important place in medical services. There is a growing need here for expansion, upgrading, and co-operation. Banbury, High Wycombe and Amersham, and Newbury should each have a hospital with a unified service and self-supporting to a considerable extent. At Maidenhead more co-ordination is required; there is a "magnificent opportunity" here for unification. Reading has two hospitals—one municipal and the other voluntary—neither of them on an adequate site; it should have one main hospital situated away from the centre of the town and a main health centre situated centrally, with subsidiary health centres or local hospitals elsewhere.

CAMBRIDGE AND EAST ANGLIA

The surveyors in this area, which includes Norfolk, Suffolk, Cambridgeshire, Huntingdon, and Soke of Peterborough, with a population of 1,250,000, are of opinion that there should be one key hospital for the whole region, fully staffed and equipped to deal with all types of cases; a principal hospital for each of the administrative areas and available for all types of service with the exception of neurosurgery and thoracic surgery and to some extent radiotherapy, county general hospitals with 100 or more beds; and, finally, local hospitals of under 100 beds, mainly staffed by general practitioners. They estimate that 3.5 beds per 1,000 are required for the acute sick, entailing an addition of 1,150 beds to those at present available. This could be made up chiefly by extensions of Addenbrooke's Hospital, Cambridge, and the principal hospitals at Peterborough, Norwich, King's Lynn, Ipswich, and Great Yarmouth. With the exception of the Norfolk and Norwich

Hospital, the larger hospitals are understaffed. Apart from gynaecological and ear-nose-and-throat surgeons, there do not appear to be any consultants practising a special branch of medicine and surgery to the exclusion of general work. Radiotherapy has so far been developed only in Cambridge. There are also held to be too many hospitals of considerable size and serving large areas which have general practitioners functioning as the specialist staff.

Addenbrooke's is proposed as the key hospital of the region, and five other county general and five local hospitals are suggested for the Cambridge area. In Suffolk the principal hospital, despite its grave staffing defects, would be the East Suffolk and Ipswich, with two county general and five local hospitals in that county; and in Norfolk the principal hospital would be the Norfolk and Norwich, with four county general and seven local hospitals. Arrangements for x-ray and radium therapy in this region are held to require considerable organization and development. The surveyors suggest one main centre at Addenbrooke's, with full equipment, and two or three subsidiary centres at Norwich, Ipswich, and possibly Peterborough.

For the chronic sick, on the basis of 2 beds per 1,000 population, just over 1,000 beds will be needed. Taken as a whole, especially in the rural districts, the infirmaries of the public assistance institutions are "of a very low standard and are no credit to the counties concerned." An exception is made of the institution at Peterborough, "which might well serve as an example to neighbouring authorities of what can be done under present powers"; the institutions at Norwich and the county infirmary at Cambridge also do not come under the stricture. Recommendations are made for the appropriation or other rearrangement of the existing public assistance hospitals. In West Suffolk it is considered that the needs of the chronic sick could best be met by converting the Bury St. Edmunds public assistance institution into a county hospital. Detailed recommendations are also made for improvements in maternity accommodation, orthopaedic services, and sanatoria for pulmonary tuberculosis. A linkage of hospitals for infectious diseases is suggested whereby each unit over the widest possible area of administration would work in liaison with all the other units concerning admission of patients and use of staff.

ASSOCIATION OF SURGEONS

On May 7 the Association of Surgeons of Great Britain and Ireland entertained to dinner a number of eminent representatives of French and Belgian medicine, and the Directors-General of the armed Forces. The President of the Association, Sir Max Page, had a gracious tribute paid to him by Sir Claude Frankau, who described him as an outstanding example of a vanishing type of surgeon—the general surgeon. He lauded his skill as a man with equal facility in operating on congenital pyloric stenosis and on the femur. In reply Sir Max welcomed the flourishing state of the Association of Surgeons, and extended a warm greeting to their surgical colleagues from the Continent—a welcome that was endorsed in fuller detail by Sir Alfred Webb-Johnson in his toast "The Guests." Extolling the merits of professional dinners, Sir Alfred said the late Sir Buckton Browne told him that it was at a dinner that Lister had first heard of the work of Pasteur. He called upon each distinguished foreign guest present to stand up on mention of his name, and as each man did this with evident pleasure, he was warmly applauded. Ending on a solemn note, Sir Alfred said how much they had admired the patience, fortitude, and faith of the French nation during the hard years, and he thanked them for all they had done in helping our men across the frontier between France and Spain, and helping the parachutists who dropped in France on their dangerous missions. And he thanked, too, "Your wonderful women."

Prof. Lenche, who is an Honorary Fellow of the Royal College of Surgeons, graciously replied on behalf of his French and Belgian colleagues—both those present and those who had been unable to come. He went on to say how close their hearts had been to ours during these past years. He recalled hearing by radio the news that the College had been bombed. He pleaded for still closer contact between the medical professions of the two countries in the future. The young men, he observed, must exchange ideas across the Channel and read each other's literature.

Sir Alexander Hood, who also replied for the guests, spoke of the importance of morale in war and of the part played in sustaining this by the medical profession, and especially by the surgeons. No army had ever had such excellent medical services as the British

Army in this war. The surgeons had done much to plan the Army Medical Services, and he gave as an instance the great help they rendered in tackling the difficult problems of the surgical services for D-Day. Sir Alexander said that special surgery had come very much to the fore in the Army Medical Services between 1939 and 1945. The fact that the soldier knew that, if wounded, he would have first-class expert treatment in a forward area had an enormous effect on the morale of the troops. Sir Alexander paid a tribute to the consultant surgeon for "spreading the gospel of surgery," especially among the younger men. Finally he made a plea for continuing in peace the close contact there had been in war between the Army and civilian medical services. They did not want, he said, once more to go into isolation.

A HUNTERIAN DINNER

The Hunterian Society celebrated the 218th anniversary of the birth of John Hunter by a dinner that was much enjoyed by all those present. Toasting the Hunterian Society, Mr. Justice Hilbery compared his own state to that of John Hunter, who felt so apprehensive before lecturing that he used to take laudanum to soothe his nerves. Hunter, he observed, must have been a difficult man to live with because most of the rooms in his West-End house were full of anatomical specimens. Stressing the value of tradition in the learned professions, Mr. Justice Hilbery praised the Hunterian Society for its continued activity since its foundation in 1819, twenty-six years after Hunter's death. The medical profession, he concluded, was now in danger of a fracture-dislocation with its past.

In reply the president of the society, Mr. Mortimer Woolf, recalled Rudyard Kipling's classification of people into two kinds—doctors and patients. It was now proposed to subdivide the patients into those who when ill chose to lie in a bed or institution of their own choice and those who chose to lie in State.

Mr. A. E. Porritt gave a warm welcome to the guests, and mentioned that Dr. Mervyn Gordon had made a gift of Hunterian relics to the society. Responding for the guests, Lord Moran touched on a number of interesting themes. He recalled Bacon's observation that how a thing happens is more important than why it happens. Lord Moran believed that the differences between physician and surgeon were really small, and referred to Wilfred Trotter as the last of the physicians who did his own cutting. He deplored the fact that the learned professions no longer had leisure, with the result that they were ceasing to be learned. Sir Alfred Webb-Johnson, who also responded, said that Hunter's statue in Leicester Square had been damaged by rowdy soldiers. The statue had been sculpted by Woolner, who was a friend of Darwin's. Woolner, he added, had also sculpted a Puck, to whom he gave sharp projecting tubercles to the ears. Darwin called it Woolner's tubercle. Why, Sir Alfred asked, did we call it Darwin's tubercle?

CANADIAN WAR HOSPITAL FOR BRITAIN

On April 29 the Canadian Red Cross Society hospital in the grounds of Cliveden, Lord Astor's Thames-side estate, became the property of the Crown, as a gift from the Canadian Government and people to Great Britain. Col. R. W. Frost, overseas commissioner of the Canadian Red Cross, presided at the ceremony, when Lord Bennett handed the key of the main entrance of the hospital to Mr. Aneurin Bevan, Minister of Health. In the name of the Government of Canada Lieut.-Gen. J. C. Murchie handed over that part of the equipment and fittings which the Canadian Army Medical Service has added to the hospital. Mr. Bevan, acknowledging the gifts, said he was delighted to accept them on behalf of the British nation as a further example of the warm-hearted generosity of the people of Canada. The British Government intended to use it as a special hospital for research into rheumatic conditions in children, and it would also serve general hospital purposes for people in the neighbourhood. It will be known in future as the Canadian Red Cross Memorial Hospital, in honour of the Canadians who gave their lives in the war.

The Friends Ambulance Unit is a voluntary pacifist association of some 700 men and women who have organized themselves for the relief of suffering wherever it occurs. The war, and the privation and suffering which followed in its wake, took them into many parts of the world and set them a multiplicity of tasks. Though organized in the first place for wartime emergency service the F.A.U. has tried to continue its existence as long as the need for its special kind of contribution to the work of relief exists. It is assumed in the present plans that its work will come to an end by June 30, 1946. An illustrated account of work in various stricken countries is given in the sixth annual report, published from 4, Gordon Square, W.C.1.

Correspondence

The Health Service Bill

SIR,—The implications of the Health Service Bill are now available for study. Its author considers that the essential partners in the scheme—the doctors and the hospitals—must be rolled out by the smoothing-iron of Socialist uniformity. It is, in fact, the first step towards full regimentation of both doctors and patients, and, as everyone knows, it is the first step that matters. After that first step it is harder, and finally impossible, to turn back. Once Mr. Bevan has got his Bill it will be easy for him to issue regulations and use his wide powers to make doctors full-time salaried servants of the State. The public would then have to queue up at health centres like soldiers at sick parade. The public prefer the family doctor as a servant and friend; the Socialists want to turn him into a servant of the State.

In fact, we are back to the days of intolerance. In the past it was the fervour of Dissenters which made the strength of great political movements. Surely the relationship of man to man is of more importance in so personal a matter as healing of the sick than authority's need for central control. All parties and the medical profession are agreed that the aim of this great scheme should be to bring to those in need an equal chance of sharing in the modern advance of medicine, and much more success could have been assured if a proper understanding had been reached as to the limits to be drawn between the province within which the State should organize and that in which the individual should give rein to his creative genius.

If Mr. Bevan pursues his present course and enforces something on the doctors they dislike, and indeed on a large proportion of the public, then, as I indicated in a letter in September, 1945, he will create one of the greatest blunders of his career, which in due course will recoil upon the authority of the present Government.—I am, etc.,

London, W.1.

NORMAN P. HENDERSON.

SIR,—Prof. W. M. Frazer's letter (April 20, p. 621) stimulates comment. He states: "Week by week in the *Journal* we see a spate of high-sounding words which bemuse rather than instruct"; very well, then, let us face facts.

The keynote of the Health Service Bill is the Minister's undisputed authority over the whole of the nation's health services. The Bill may be "most courageous," it may be "prompted by an able Minister," "who conscientiously believes etc.," but this is no time for platitudes; this Bill means State control of the medical profession. "We are the masters"; thus speaks the Attorney-General. Very soon the Bill will be given the force of law; very soon we shall see what has happened to all the proposed amendments. "We shall know how to deal with organized opposition to the will of the people"; thus threatens one Cabinet Minister after another.

We are in for a hard fight, let there be no mistake about that. Those who are alive to the danger will agree that criticism of the B.M.A. at the present time is tantamount to high treason however justifiable it may be at other times. The profession must be content now to repose full confidence in its leader and give them loyal and unfaltering support. "We would not ask the community to allow us to retain a similar measure of freedom to that accorded to other professions," says Prof. Frazer. Whatever may be expected of the community, it is our bounden duty to rely on ourselves. If freedom is worth having it is worth fighting for, the choice lies between this acquiescence in totalitarianism. The community will give its verdict in due course.—I am, etc.,

Keighley, Yorks.

H. M. HOLT.

SIR,—I feel I must join other correspondents in calling for simplification and hardening of the policy of the B.M.A. The first essential is honesty of motive. The interests of the public are being safeguarded by the Government in the very introduction of a National Health Service. While being in favour

of this service, our motive is candidly to protect our own interests by fighting points in the service which are at variance with them.

There are three points on which the majority of the profession seem to differ from the Government. One is on the principle of becoming completely controlled by the State owing to compulsory surrender of goodwill and to payment by salary. The second is likely to be the total amount of remuneration to members of the profession, when this is published. The third is the loss of freedom of enterprise of the voluntary hospitals through their compulsory total acquisition by the State.

Unless these points are adjusted by negotiation between the profession and the Government what action can be taken? The proposed negative action of refusing to join the scheme is not calculated to give practitioners confidence in the speedy solution of the differences. Early concerted action by (say) refusal to sign certificates will be essential to bring the need for negotiation strongly before the Government. Unless the B.M.A. Council takes the lead with some such action most doctors will be unable to afford financially, despite the B.M.A.'s fighting fund, to lose their income and capital by refusing to join on the appropriate date whatever scheme the Government pleases to introduce.—I am, etc.,

Have Sussex

E. N. G. GORMAN.

SIR,—To fight with every legitimate weapon to secure amendments to the National Health Service Bill is necessary, urgent, and constitutional. To plan with fighting fund and threatening word to make an Act of Parliament of which we disapprove unworkable is revolutionary. It is no sufficient answer to claim that we are fighting for the public good. Obviously other groups displeased with other Acts of Parliament could make a similar claim, and would be the more likely to do so since this method of bringing the law into disrepute had been blessed by so respectable a body as the B.M.A.

Surely, especially in these restless and troubled days, there is here a principle involved greater even than the Council's Principles, important as these are. Is there time to consider calmly along what road we are planning to march, what kind of forces are likely to join with us on the way, and where this revolutionary army, swollen by a multitude of recruits as it marches, and led by the Council of the B.M.A., is likely to arrive.—I am, etc.,

Nuneaton.

T. H. FORREST.

SIR,—The National Health Service Bill will in due course become law, in spite of opposition by any individual doctor or group of doctors. Why? Because it is the will of the people expressed by their freely elected representatives in Parliament, to reorganize the country on urgent and truly economic grounds. Every organization and interest in these islands will in turn come up for scrutiny and ruthless reorganization. Each one of us who has the country's interest at heart must not stand in the way of progress, for it is progress. In order that this country can become great again many pre-existing ideas must be scrapped for the smooth running of the whole. I submit that the medical profession will recover from this courageous major operation and enter into an uninterrupted convalescence.—I am, etc.,

Compton

T. W. ROTHWELL.

Assistants and the Bill

SIR,—Among the numerous letters on the effects of the proposed health service I have seen nothing about what strikes me from my own experience as one of its most important deficiencies—the abolishing of the status of assistant. Before entering general practice I had longer than most in resident hospital posts, but I should be the first to admit that what I learned from my principal when I was an assistant was a most important part of my training, which I should have sadly missed had I set up on my own account.

I have tried in vain to see how under the proposed scheme the newcomer to practice can be "introduced" unless he is attached in some subordinate capacity to an older hand. With

a capitation basis it might be obligatory for a doctor, on reaching an agreed limit of numbers, to employ an assistant; but where salary is the basis, and each doctor is responsible only to a committee, there can be no smooth and natural succession from the older doctor to the younger, nor can there be the gradual slackening off of a tiring old man, which is the present general method.

This has seemed to me from the beginning the strongest argument for the retention of the private ownership of practices. Both the patients and the succeeding doctor must suffer from the sudden disruption of practices which seems inevitable under the proposed scheme—I am, etc.,

Sheborne

R. McINTOSH

Penicillin and Diphtheria

SIR,—Your annotation on the action of penicillin in diphtheria (April 27, p. 656) is based solely on the experimental findings of Ercoli, Lewis, and Moench (*J. Pharmacol.*, 1945, 84, 120) and disregards those of R. M. Young and G. M. Mood (*J. Bact.*, 1945, 56, 205) which seriously conflict with them. You quote the former as stating that a concentration of over 1 unit per ml. of penicillin is required to inhibit the growth of *C. diphtheriae*. Young and Mood tested six strains and found all to be inhibited by concentrations between 0.004 and 0.06 unit per ml. (This is comparable with my own findings in thirty strains, mostly gravis.) They also found that experimental infection by *C. diphtheriae* in guinea-pigs could be prevented by extremely small amounts of penicillin mixed with the inoculum, or cured by larger doses given as long as 23 hours after inoculation with a larger dose of culture.

The effect on the results of such experiments of the routes of inoculation and other factors appears to need further study, but I submit that to base a definitive judgment solely on the findings you quote is unjustified. Your conclusion that penicillin "would have no appreciable value for the treatment of patients with established diphtheria" is premature and unsupported by my own experience, as described in the letter which you published on April 20 (p. 627). It could have been confidently predicted without the experiment you quote on this point that penicillin would not influence the action of diphtheria toxin. On the other hand, if administered in sufficient dosage to inhibit the growth of bacilli in the lesion it will prevent the formation and absorption of further toxin, and it is reasonable to suppose that this should have a further influence on the course of the disease.

My experience, which now extends to five cases, combined with my observations on the fate of penicillin-sensitive organisms in deep gum and tonsillar infections treated with general penicillin, leads me to believe that large doses—at least 500,000 units a day—are necessary to ensure penetration into the membrane, whether from the circulation or via the saliva. The effect is rapid and treatment need only be continued for three days.—I am, etc.,

St Albans

DAVID A. LONG,
Penicillin Officer, H.M. End Hospital.

Unusual Reaction to Penicillin

SIR,—In penicillin-treated syphilis a febrile reaction, occurring within twenty-four hours (or more exceptionally after ten to twelve days) of commencing treatment and frequently associated with exacerbations of clinical manifestations of the disease, is commonplace, and its incidence has been variously reported as from 10 to 50%. The chief practical application of this lies in the fact that the flare-up of an advanced syphilitic lesion in a vital organ or tissue may have disastrous, and even fatal, consequences. The phenomenon is of the nature of a Jarisch-Herxheimer reaction, and is familiar to all venereologists.

Capt. M. Swardlow (April 27, p. 664) has doubtless excluded the possibility that his patient was suffering from coexisting syphilis when treatment for gonorrhoea commenced, and may have omitted to mention this on the grounds that it was routine procedure. I cannot shed any further light on his case, but his letter may serve as a useful reminder to those with a limited experience of the use of penicillin in venereal diseases. As increasing supplies of penicillin become available to non-specialist practitioners, doubtless more and more cases of gonorrhoea will be treated with this powerful therapeutic agent by

doctors with limited experience of its use in V.D. The two chief lessons to be learned derive from the fact that both the gonococcus and the *Treponema pallidum* are penicillin-sensitive organisms. Therefore: (1) Before exhibiting penicillin in a case of gonorrhoea (or, indeed, in any general medical or surgical condition) the practitioner should bear in mind the possibility of coexisting syphilis, particularly with clinically active lesions in vital tissues—e.g., cardiovascular and central nervous systems. (2) The clinical and serological surveillance of penicillin-treated gonorrhoea, to exclude syphilis contracted at the same time and masked by penicillin because of its longer incubation period, must be systematic, thorough, and prolonged. In cases of doubt arising out of either or both of these conditions the advice of an experienced venereologist should be sought.—I am, etc.,

Inverkeithing, Fife.

RICHARD SCOTT.

The "Intractable" Vesico-vaginal Fistula

SIR,—Dr. Donald Mackay's interesting report of the spontaneous closure of a large vesico-vaginal fistula (April 27, p. 650) is a useful reminder that this injury, so often regarded as intractable, is in fact possessed of a strong tendency to spontaneous cure. This is particularly so when the fistula is the result of the tearing of otherwise healthy tissue rather than the loss of tissue by necrosis. The first type behaves in this respect like the deliberate vaginal cystotomy which was much used by a previous generation of gynaecologists, and which invariably closed, it seems, within a few days. In several cases in which I have resorted to vaginal cystotomy spontaneous cure has always quickly occurred without the need for suturing. Dr. Mackay's case is specially interesting inasmuch as the closure took place without the help of urethral drainage, which is, of course, indicated after cystotomy.

Dr. Mackay comments on the difficulty of exposure of the fistula. This difficulty may be very great, but is, in most cases, overcome by the use of a generous episiotomy and the adoption of the knee-chest position as recommended by Sims in his pioneer work. I have found Grey Turner's modification most helpful. The anaesthetized patient is rolled on her face, is drawn by her legs to the bottom of the table, the legs flexed at the hips, and the knees placed on, and banded to, a low stool: the table is then lowered until the pubic region is just clear of the top. Whereas the true knee-chest position is difficult to maintain, this modified position can be kept up without difficulty for long periods.

I deplore the pessimistic impression conveyed in Dr. Mackay's report regarding the curability of vesico-vaginal fistulae, and the implication that transplantation of the ureters is an operation frequently required. Mahfouz Pasha,¹ with experience of more than 400 cases—many of a very severe variety—reports a cure rate of 95% in the last 100 cases. Writing of the abdominal and transvesical approach he says: "For the last eight years I have not resorted to any of these abdominal operations; I find the vaginal route safer, and if I fail to close the fistula by the vaginal route I seldom succeed to do so by the abdominal." In my own much smaller experience of 30 vesico-vaginal fistulae it has been possible in all of them to repair the fistula by the vaginal approach alone, using, for the most part, a simple Sims's type operation (one patient is still under treatment with every prospect of cure). Most of these were cases of long-standing incontinence—one as much as 32 years—and most of the patients had had multiple previous operations, many by the abdominal or transvesical route. In view of this satisfactory experience with the vaginal operation I disagree with the pessimism so often expressed regarding the treatment of this injury. The most difficult case is that in which there has been an extensive loss of tissue at the vesico-urethral junction; in it a perfect anatomical repair may be marred by a subsequent severe stress incontinence of urine. In these cases relief may sometimes be obtained by the use of a pessary to press on the urethra, or, more certainly, by the use of the Aldridge fascial-sling operation.²—I am, etc.,

Nuffield Department of Obstetrics
and Gynaecology, Oxford.

Iritis in the Rheumatic Affections

SIR,—Prof. Arnold Sorsby and Dr. A. Gormaz (April 20, p. 597) wrote an interesting paper on iritis in the rheumatic affections. They made the important observation that iritis occurs in some 5% of cases of rheumatoid arthritis, and again drew attention to the incidence of iritis in ankylosing spondylitis. The rest of their paper, however, only serves to show how completely meaningless are the terms "rheumatism" and "rheumatic." They investigated the incidence of iritis in rheumatoid arthritis, acute and subacute rheumatic fever, Still's disease, fibrositis, osteoarthritis, ankylosing spondylitis, gout, and sciatica. Rheumatoid arthritis, Still's disease, and ankylosing spondylitis are no doubt closely related to each other from the point of view both of aetiology and of pathology, but there is no satisfactory proof that they are in any way related to acute and subacute rheumatic fever. Though both groups of conditions may have an infective origin, this has not been proved.

Osteoarthritis is a degenerative condition, and is often a misnomer in that what is called osteoarthritis is commonly no more than the presence of osteophytes quite unrelated to joints. Although gout may sometimes give rise to diagnostic difficulty, there is nothing to suggest that its causative factors are in any way related to those of the other conditions under discussion. Similarly, sciatica has nothing whatever to do with any of these conditions. It is, therefore, not surprising that they found no significant incidence of iritis in osteoarthritis, gout, or sciatica. Indeed, the only feature common to all these conditions is pain, and on this basis "rheumatism" might just as well embrace such unallied conditions as trigeminal neuralgia, tabes dorsalis, or angina pectoris. Nor is the absence of iritis in "fibrositis" unexpected. This latter must surely be the biggest diagnostic rubbish heap in current medicine; the last three cases bearing this label that have come to my notice have respectively been chronic empyema, lobar pneumonia, and metastatic carcinoma of the spine, though the bulk of cases so labelled are, in fact, examples of psychogenic pain. I have long felt that the terms "rheumatism" and "rheumatic" are so devoid of meaning that they should be expunged from the medical vocabulary or limited to acute and subacute rheumatism or rheumatic fever.—I am, etc.,

Leeds.

HUGH G. GARLAND.

Sjögren's Syndrome with Rheumatoid Arthritis

SIR,—Dr. F. Parkes Weber in his letter (May 4, p. 700) questions whether anyone in this country has seen rheumatoid arthritis in patients suffering from Sjögren's syndrome. If he will be good enough to come round here I can show him several such patients, including one now receiving in-patient treatment. Far from being a curiosity in Sjögren's syndrome, rheumatoid arthritis is an essential feature of the condition, and I hesitate to diagnose keratoconjunctivitis sicca unless the patient shows evidence of rheumatoid arthritis.—I am, etc.,

Royal Eye Hospital, London, S.E.1.

ARNOLD SORSBY.

Partial Deafness of the Elderly

SIR,—Now that I have myself become a victim of this very common form of deafness I realize that the public (and most doctors) are unaware of its peculiarities. If these were widely comprehended, a little consideration would enable speakers—in public, in private, and on the wireless—to become intelligible to thousands of these elderly unfortunates. The remedy usually applied is to shout. This is not only unnecessary (except in advanced cases) but is resented as calling attention to their infirmity. No, the main defect is a blurring of the words together when people talk too quickly or indistinctly; also if two people talk at once or if there is another noise, such as a passing aeroplane.

The defect seems to me analogous to an old piano in which the dampers have become worn so that the notes run together if played too loud or quickly. Hence, in conversing with one of these unfortunates, it is considerate and polite to face him so that he can see the movement of your lips, and to speak more distinctly and deliberately than is customary with most people, especially the young. For this and more important reasons, children should be taught not to speak in a slovenly

manner. Speech is an intricate and important cerebral activity executed by countless nerve cells which need educating (as in Scotland). Slovenly speaking means a slovenly brain.

On the wireless (relayed) most of the announcers are unintelligible to me because they talk too fast—or, provokingly, one may hear all the sentence except the end, when the voice is dropped. (This breaks one of the first rules in public speaking.) I can hear every word of a deliberate speaker like Mr. Churchill. The Brauns Trust transmission is always inaudible to me owing to blurring and booming. I listened once to a fine wireless set provided with a "sharpener." When this device was connected I could hear every word.

With the stethoscope I can hear the faintest heart murmurs as well as any of my house physicians. For years I have tested the merits of a stethoscope by applying it to the ball of my thumb. Contractions of its adductor muscle produce a sound of constant intensity which I hear as well as ever. I still prefer my old stethoscope because it has two bells either of which can be twisted into position. (1) a $1\frac{1}{2}$ in (3 cm) diaphragm for the lungs and faint aortic leaks, (2) a bell with rubber rim for mitral murmurs emaciated patients and blood pressure measurements.

I can hear the slight sound of a cigarette extinguished in water, yet in conversation or on the telephone I often have to say "Please repeat more slowly." High notes, including the telephone bell, are badly heard. I describe my own experiences because they must be typical of thousands of miscomprehended mortals. I withhold my name chiefly because I hope the public press will broadcast some of these hints—I am etc.

M D

Ocular Signs of Vitamin Deficiency

SIR.—In your issue of April 6 (p. 546) Dr. R. E. Wright questions the validity of the statement made in an annotation on "Ocular Signs of Arboflavinosis" (Dec. 22, p. 889) that corneal vascularization "has been noted as a result of vitamin-A deficiency." This statement was made to stress the non-specificity of corneal vascularization as a pathognomonic sign of arboflavinosis. Although it may occur in riboflavin-deficient subjects it is seen, in a variety of conditions such as vitamin A deficiency, tryptophane deficiency, injury to the corneal epithelium by irritants, diseases causing pannus such as trachoma, phlyctenular keratitis and any superficial keratitis.

Corneal vascularization as an early sign of vitamin-A deficiency was described by Wolbach and Howe (*J. exp. Med.*, 1925, 42, 753) and by Bessey and Wolbach (*J. exp. Med.* 1939, 69, 1). Keratinization occurs first and then corneal vascularization which is indistinguishable from that of riboflavin deficiency. It is a very early change, and it is possible that native patients in the East are seen only when their eyes are badly affected when any corneal changes have progressed, and the eye has frequently become secondarily infected.

Dr. Wright hopes that we are nearing the time when vitamin deficiencies will be confirmed in the laboratory. Unfortunately the laboratory diagnosis of avitaminosis has many pitfalls. Authorities are not agreed on normal standards for vitamin levels in the body fluids, different techniques give different results, individuals vary widely in their daily requirements and in their absorption, storage, and excretion of the vitamins and some vitamins can be synthesized by bacterial action in the human gut and are possibly absorbed. Also vitamin deficiencies are multiple and very rarely single unless produced artificially or by special diets. These are some of the complications encountered. There are many others—I am, etc.

YOUR ANNOTATOR

Smallpox in the Vaccinated

SIR.—Infant vaccination may modify the disease for very many years. A soldier returning from India has recently introduced smallpox into Essex and infant vaccination protected many adults. The unvaccinated died. The cases may be divided thus:

	Cases	Deaths
Successfully vaccinated in infancy and successfully re-vaccinated	3	2
" " " " " " " "	2	2

Three of the cases vaccinated in infancy only were aged 54, 59, and 69, respectively. If the population had been completely unvaccinated, numerous contacts with the original soldier, a highly modified case, would have contracted virulent smallpox. As it was, infant vaccination protected many persons completely and modified the disease in the few that developed it before they were revaccinated. Does Dr. Killick Millard (April 20, p. 625) consider that this protection from the undiscovered highly modified but infectious case is not worth having?—I am, etc.

W. F. CORFIELD
Medical Officer of Health

Medical Supplies on Merchant Ships

SIR.—The letter by Dr. J. S. Hall (March 30, p. 504) criticized the medical equipment of merchant ships but unfortunately did not go far in suggesting improvements.

The first (and false) impression is that the medicines supplied are childishly inadequate. This arises because the casual medical visitor is faced by an array of bottles labelled "sore throat mixture—good for indigestion," "sweating mixture" and so on, with directions given in the simplest language. A study of the standard prescriptions in the scale of stores in the appropriate part of the *Shipmaster's Handbook* will reveal that these are stock medicines comparable to *N.H.J. Formularies* preparations. It is quite true that NaCl and glucose is a more rational remedy than the carminative "fireman's cramp mixture" and no doubt, the V.D. clinics would prefer the undiagnosed peritonitis to be dressed with simple saline rather than "black wash." Sulpha-thiazole is already provided, but acriflavine could oust the traditional iodine with advantage, especially in ships carrying native crews, who may neglect abrasions rather than attend for an unnecessarily painful dressing. These items might well be brought up to date at the next revision of the *Shipmaster's Handbook*.

In my opinion the big defect in treatment in foreign trade ships is that too little can be done for complicated cases of malaria, especially cerebral malaria. It must not be forgotten that malaria is one of the common occupational diseases of seamen. Many cerebral cases are missed because malaria is never suspected. Any man suffering from coma with pyrexia, even if he collapses in an overheated stokehold or engine room in the Tropics, should be treated as a case of cerebral malaria unless a clear alternative diagnosis is indicated. With the exception of ships bound south through the Red Sea direct from North European or U.S.A. ports it may be argued that in any region where the crew are exposed to extremes of heat they have also been exposed to malaria. Specific treatment apart from the handling of cerebral malaria and heatstroke is reduced to palliative nursing, and by regarding all coma-fever cases as cerebral malaria to be treated with quinine by injection an occasional heatstroke may receive a (to him) harmless and unnecessary dose of quinine while it is made certain that no malaria case misses this life-saving procedure.

In general such injections by laymen should be intramuscular though many officers are prepared to put a needle in a vein. The equipment provided could be ampoules and syringes or a specially developed "tubonic" ampoule or a syringe with cartridge loading. (In connexion with this it is inevitable that penicillin will be included in the list of medical stores, and its reconstitution with distilled water or the repeated use of a rubber-capped bottle has drawbacks in lay hands which might be avoided by the use of expendable cartridges.) The provision of such antimalarial facilities in the early days of the war would have saved many lives in ships touching at West African ports.

While on the subject of injections I should like to evoke the opinion of medical officers of the various fishing organizations on the following. I have not been to sea in a steam trawler since my student days, but I well remember having to exercise my professional talents even then. The number of fractures sustained in handling the heavy gear in winter time is considerable. The shock experts may well consider what to do with a trawlerman with a fractured femur put up with the first aid equivalent of a "long Liston" and lying in a springless bunk which moves every way as the vessel steams, often for several days, to get him into port and a hospital bed. In my opinion no trawler should put to sea without a dozen "tubonic" ampoules of morphine and a tube of 1/2-gram (32 mg) morphine tablets for oral administration. Simple instructions are easily carried out, and a rule of an injection at the time of the

accident with another in an hour if the pain persists, followed by a tablet by mouth to be given whenever the patient is fully conscious and the pain is coming back, could only be beneficial and would save much unnecessary suffering.

As orthopaedic fashions and the treatment of burns change so rapidly it is difficult to see what alterations are acceptable to the experts. It is sufficient to say this. Let the reformer go slowly. The shipmaster or chief steward has little time to keep up with a constantly changing scale of medical stores, and it is better that he should have a small stock of sound and essential remedies and appliances which he understands and can handle with confidence. The wartime American scheme of training chief stewards up to pharmacist's mate (sick-berth petty officer) standard has much to recommend it, but until a similar scheme is introduced into the Merchant Navy the medical equipment cannot be increased to any great extent with any guarantee of efficient use.—I am, etc.,

W. S. PARKER,
Surgeon, M.N.

London W 11

Diuresis by Suggestion

SIR,—Mr. A. Basil Rooke's interesting observation of this phenomenon (April 13, p. 589) reminds me of a case I saw some years ago, in which similar observations were made.

In June, 1940, at a Northern Emergency Hospital, a man of 35, wounded in the evacuation of Dunkirk, was admitted with a shrapnel

wound in the left posterior renal area, which had resulted in a urinary fistula. We were able, with the aid of intravenous pyelography, to locate the shrapnel at the upper extremity of the left ureter, where the opaque material could be seen escaping through the opening (see A.P. view).

It was not possible at once to remove the foreign body, so that for a week or two one was able to observe the fistula. (It is noteworthy that the shrapnel fragment worked its way slowly along the sinus and was ultimately easily removed near the surface.) During the period of observation it was found that, on inclining the patient to the left, urine was seen to drip at regular intervals from his fistula, so that a rough idea of the rate of excretion could be obtained. I was able in this way to test the effects of various stimulants, both mental and physical, on the excretory rate. I found, like Mr. Rooke, that the mere mention of pleasant drinks and foods was followed, after a

short "lag" period, by a definite measurable increase in the rate of flow.

This phenomenon reminds one irresistibly of the valuable observations of Wolf and Wolff (*Human Gastric Function*, Oxford University Press, 1944) on the response of the stomach in terms of vascularity, secretion, and motility to the mere discussion of delectable dishes, without the sight, taste, or smell of food. These observations were made on a patient with a large gastrostomy, the opening of which was surrounded by a protruding collar of prolapsed mucosa. When discussion of appetizing food was begun the membrane became redder (from 40 to 70% according to their scale of designation), indicating a marked increased mucosal vascularity, and the output of parietal (oxyntic) cells was increased proportionately. Actually tasting the food added little to these effects. Earlier authors describing this psychic secretion were Beaumont, 1833; Longqvist, 1906; Pavlov, 1910; and Mantelli, 1911. Also, it is interesting in this respect to recall the work of Babkin, who showed that mankind's favourite hot drinks (i.e., tea, coffee, and cocoa) are excellent stimulants of secretion.

In the case of the stomach the nerves responsible for vasodilatation are the vagi, which are, of course, readily influenced by the cerebral cortex and hypothalamus. The renal plexus, from which the kidney derives its autonomic nervous supply, is formed by filaments from the coeliac plexus, the aortico-

renal ganglion, and the aortic plexus. It is also joined (according to Renner) by the lowest splanchnic nerve and by branches from the vagus, these being mainly vasomotor in function. It is therefore quite conceivable that, in parallel with parasympathetic activity in the stomach and elsewhere, dilatation of the renal capillaries with activation of "quiescent" glomeruli should occur in response to a suggestion of some pleasant food, with consequent relative diuresis.—I am, etc.,

Queen Elizabeth Hospital, Gateshead.

MANUELL ANDERSON.

"Congenital Malaria"

SIR,—Recent correspondence on "congenital malaria" prompts me to add the following observations on the subject.

In the course of a malaria survey in East Africa before the war I examined 143 blood smears from newborn African infants and found 11 infants showing typical *P. falciparum* parasites; but none of those 11 infants developed clinical malaria in the first week of life. The only figures I now have available refer to the first 54 trials, which yielded the following results in smears from the sites given:

Umbilical Cord		Child's Heel		Placenta	
<i>P. falciparum</i> ...	5	<i>P. falciparum</i> ..	7	<i>P. falciparum</i> ...	4
<i>P. malariae</i> ..	1	<i>P. falciparum</i> ..	1	<i>P. malariae</i> ..	2

Thick and thin films were prepared and stained by the "Shute method," using buffered distilled water and acetone-free alcohol. Special precautions were taken against carrying over parasites from the mother's blood when making the film from the child's heel.—I am, etc.,

Preston.

R. MACKAY.

SIR,—Dr. J. S. English (May 4, p. 701) perpetuates the fallacy of previous reporters on this subject in ignoring the possibility that a malarial infant 6 days old or thereabouts could have acquired the infection post partum. He says that in his case "the malaria was transmitted before birth"—i.e., congenital—and expresses surprise "that there are not more cases on record." My submission, as suggested in my previous letter (April 13, p. 586), is that there are in fact no proved cases on record. As a student more than ordinarily desirous of enlightenment on this difficult subject, and echoing, as I imagine, the desires of many other students and practitioners of tropical medicine, I suggest that information from an acknowledged authority as to the absolute criteria required to support a diagnosis of congenital malaria would be welcome.—I am, etc.,

"STUDENT NO. 2."

Alien Doctors in Britain

SIR,—In the near future a number of medical men will be released from the Forces whose position presents an urgent problem. I am referring to the doctors of Allied and friendly alien nationality who served during the war in H.M. Forces and who, for various reasons, cannot return to their countries. As things are at present, on demobilization they are automatically debarred from practising their profession here because most of them do not possess British qualifications. In order to obtain these it is necessary to sit for examinations after studying at a recognized medical school for periods ranging up to three years; in practice it may be much longer, as medical schools are reluctant to admit these doctors as students in view of the shortage of accommodation.

For the majority it is impossible to comply with these conditions—mainly for financial reasons. They are, therefore, left stranded. Surely these men to whom we entrusted the care of our fighting men should be given some consideration, and some effort should be made to modify the very stringent regulations, facilitating their admission to the *Medical Register*.—I am, etc.,

London, W.1

E. M. HERBERT.

Hospitals and nursing homes may now have "dunlopillo" mattresses and pillows, as may invalids against medical certificates for use in their own homes. The Board of Trade has issued a licence to the manufacturers for a limited number to be supplied over the next six months.

Obituary

SIMON FLEXNER, M.D., LL.D., D.Sc.

Dr Simon Flexner, is already announced died in New York on May 2 aged 83. One of the leading bacteriologists of his time he was director of the Rockefeller Institute for Medical Research from 1903 to 1935, when the title of emeritus director was conferred upon him. During a lifetime of patient and illuminating research he distinguished himself especially by his work on terminal infections, his experimental studies on venoms on the aetiology and treatment of cerebrospinal meningitis and acute anterior poliomyelitis. His name is indelibly associated with Flexner's dysentery bacillus and Flexner's antimeningococcus serum.

Born at Louisville, Kentucky, on March 25, 1863 he graduated M.D. of the University of Louisville in 1889, he then became a postgraduate student at Johns Hopkins University, Baltimore, and attended clinics on the Continent of Europe, at Strasbourg, Prague, and Berlin, and later at the Pasteur Institute, Paris. He was professor of pathological anatomy at Johns Hopkins in 1898-9 and of pathology at the University of Pennsylvania Philadelphia 1899-1903 during which time he was also director of the Ayer clinical laboratory at the Pennsylvania Hospital. Simon Flexner began his long service with the Rockefeller Trust in 1903 when he moved to New York to take charge of its pathological laboratories which had been opened two years earlier, many of the researches carried out there by him and his staff have become part of the history of bacteriology, immunology, and experimental epidemiology. Recognition of his work came from almost every civilized country, he received honorary doctorates from many universities in America and Europe and distinctions from other learned bodies. He was elected a Foreign Member of the Royal Society in 1919, and four years later the French Government advanced him to the rank of Commander of the Legion of Honour. He had been Huxley lecturer at Charing Cross Hospital Medical School, and in 1937-8 was Eastman visiting professor at Balliol College Oxford, which elected him to an Honorary Fellowship. The British Medical Association made him a Foreign Corresponding Member in 1932. In his own country he had been a trustee of Johns Hopkins University, of the Carnegie Institute of Washington and of the Rockefeller Foundation, chairman of the Fellowship Board of the National Research Council, and of the Public Health Council of New York State, and assistant surgeon general in the U.S. Public Health Service Reserve. Besides contributing many important papers and monographs on pathological and bacteriological subjects he wrote in 1941 with his kinsman James Thomas Flexner a book entitled *William Henry Welch and the Heroic Age of Medicine*. His youngest brother, Dr Abraham Flexner, the educationist, is well known for his reports and books on medical education in the United States and Canada and in Europe.

SIR HAROLD STILES

Dr EDWIN BRANWELL writes

As a great admirer, and one who had many intimate contacts with him during the later years of his professional activity I would like to add something to what has been written of Sir Harold Stiles. His reputation as a brilliant anatomist and one of the leading surgeons of his day is well known, but he had a combination of additional exceptional faculties some of which, I would emphasize, made him an outstanding figure in the profession which he adorned. Gifted with a great charm of manner, he possessed to a most unusual degree the psychological insight which enables "the healer" to see a case from the patient's point of view. Very thorough in everything he did it was a pleasure to be asked to see a case with Stiles, for he always knew exactly the information he required and was most appreciative in acknowledging any help he might receive. Keenly interested in anything which was new to him particularly if it had a practical application, he had a thirst for pertinent knowledge. My impression is that saturation with everyday procedures, which demand so much expenditure of time and physical energy in the life of the busy surgeon, may have precipitated his retirement. A most stimulating teacher and demonstrator, Stiles had a brain which never seemed to tire. It was soon after the first Great War that Harvey Cushing, who was staying the night with him, told me of the day they had just spent together at the Edin-

burgh War Hospital at Bangour. From ten o'clock to six, with brief intervals for lunch and an afternoon cup of tea, Stiles had continued to demonstrate cases—he was not operating—and, said Cushing, he was as enthusiastic, brilliant, and interesting as "the close of the day as he had been at the beginning," "the most remarkable instance of mental endurance with which I have ever met."

When I dined alone with Stiles at his house at Great Stuart Street a few days before he left Edinburgh to live at Gullane, I asked him how he proposed to spend his time. He told me that, now that he had given up surgery, he intended to make a serious study of golf and had bought all the leading books upon the game. It was obvious that this would never satisfy his active mind, and I was not surprised to hear soon afterwards that he was concentrating upon geology. Some two years later when I asked him whether he proposed to contribute to the literature of geology, his reply was "Although I have worked harder at the subject during the past two years than I did at medicine during any two years of my undergraduate course, I realize that I have only grasped the rudiments." Stiles recognized his limitations, this indeed was one of his many characteristics. Yes Stiles was a remarkable man for, in addition to his powers as a surgeon, he had the mental aptitude, insatiable scientific curiosity, and urge of the investigator, combined with a wonderful power of concentration. He loved new knowledge for its own sake, for the problems which it raised and the mental satisfaction which their solution afforded his ever active brain.

Prof GREY TURNER sends the following appreciation

It must be over forty five years ago since Harold Stiles became an inspiration to the younger men working in surgery in Newcastle upon Tyne. His name was already prominent in cancer research and especially in connexion with the breast, but we also heard that he was rapidly becoming the leading surgeon in Edinburgh. Stiles had a thorough training in the basic subjects, especially anatomy and pathology, and in after years he always regarded such studies as of great importance as an introduction to the practice of surgery. I remember him stressing the fact that for the first ten years of his professional life he never touched a knife other than in the dissecting room. He was always a most persevering and industrious worker. His approach to surgical problems was largely anatomical, as might indeed have been expected from one who had been trained in anatomy under so great a master as Sir William Turner, and in its application when he served as house surgeon to Prof John Chene. To the end of his days he kept up this subject, and long after his retirement he expounded the anatomical basis for certain interventions which we were discussing. It was applied anatomy that made the greatest appeal, and he contributed the article on that subject to the first edition of Cunningham's textbook. I believe that his name first became prominent in surgical practice through his translation of Theodor Kocher's great work, the *Textbook of Operative Surgery*. Kocher was then regarded as the father of modern technique, and it is generally recognized that it was Stiles who first introduced the methods of dry sterilization with the use of gowns, masks, etc. into Edinburgh. Up to that time everything had been conducted on the strictly antiseptic plan, but his firm advocacy gradually made a change which eventually became general.

Though he touched many fields in surgical work probably his greatest individual contribution was on transplantation of the ureters. I saw a couple of his early cases in Edinburgh in 1905 and was tremendously impressed by the statement that these two little girls were able to sit comfortably throughout a performance of "Peter Pan." But it was his paper to the American Surgical Association at Denver City in 1911 that was the means of bringing the method he then employed before the surgical profession the world over. This marked a great advance, and a new era may be said to have dawned for the victims of congenital anomalies of the urinary tract with incontinence. It was a great delight to many of his friends that at the age of 73 he was present at a meeting of the Medico-Chirurgical Society of Edinburgh when one of the first patients he had treated by transplantation was presented in good health and enjoying complete rectal function and control 23 years after operation.

Stiles was an inspiring teacher and those who were present at the meeting of the Association of Surgeons held in Edinburgh during his presidential year in 1921 are never likely to forget that wonderful demonstration which he gave on cervical rib. It was my privilege to visit America in company with Stiles in 1906, and a week which we spent together in the Mayo Clinic will always remain memorable. He and William Mayo were greatly attracted to each other and began a friendship on that occasion which lasted throughout the rest of Mayo's life. In 1903 we also paid a short visit to some of the Swiss hospitals, including a most inspiring and profitable time at Kocher's clinic in Berne. Everything was freely open to my friend, and he was cordially received as a distinguished visitor. All American surgeons loved Stiles, and in spite of his being a very bad sailor he several times crossed the Atlantic. It was not only that they were impressed by his work but they were attracted by his personality, for he was an arresting companion and a splendid

talker, always vivacious and cheerful. He had great zest for work and was filled with enthusiasm, but he seemed to do everything at full pressure so that he took it out of himself. I have no doubt that when he unexpectedly retired from the Chair of Clinical Surgery before the normal age he was suffering from the most strenuous overwork, which continued throughout the 1914-18 war and straight on into the period when he took over the new duties of the chair.

Stiles was proud of the family tradition as doctors and often referred to his experiences of general practice with his grandparent and father in Lincolnshire. This period was dealt with in his most interesting "Reminiscences of a Surgical Training," as he entitled his inaugural address in 1919 as Regius professor. As an operator he was delightful to watch, for he was precise and accurate though deft and speedy. All his operations were planned on an anatomical basis. There was no doubt about his position and success in the Scottish capital. Stiles was among the most loyal of friends, and was always ready to help the younger men and especially those who showed enthusiasm. He was greatly attached to the first Lady Stiles and to his daughter, and they on their part sympathized and helped him in his devotion to his professional duties. His second wife, who survives him, proved a wonderful and most devoted companion, and the happiness of his last days was enhanced by her tender and understanding care.

Mr. STANLEY DODD, consulting obstetric surgeon to the Westminster Hospital, consulting surgeon to the Chelsea Hospital for Women, and consulting gynaecologist to the Bolingbroke Hospital, died in London on April 21, aged 70. The third son of Arthur Dodd of Tulse Hill, he was educated at Eastbourne College, Caius College, Cambridge, and the Westminster Hospital, where he won an entrance scholarship, and after qualifying in 1902 was in turn house-surgeon, house-physician, and obstetric tutor. He had also been senior resident medical officer at Queen Charlotte's Hospital. He obtained the F.R.C.S.Ed. diploma in 1908, was elected F.R.C.O.G. in 1929, and F.R.C.P.Lond. in 1932. While in full harness as an obstetrician and gynaecologist in London, Stanley Dodd examined for the Universities of Cambridge and London, for the English Conjoint Board, and for the Central Midwives Board. He had a happy knack of putting nervous examinees at their ease, as he was obviously and rightly more interested in finding out what they did know than in uncovering their limitations. In his chosen specialty Dodd's patent trustworthiness and quiet efficiency enabled him to dispense with mere showmanship, which in any case he was not equipped for and would have despised. He was one of the team of fine surgeons who during the quarter-century which roughly covered the reign of King George V made the Chelsea Hospital for Women a place of pilgrimage for gynaecologists from overseas. Though quiet in manner, there lurked a twinkle of the eyes which showed a sense of humour; and he was essentially a good colleague to work with. He was part author of the book *Midwifery and Diseases of Women*. He married Miss Phyllis Embury, who, with one son, survives him. He joined the B.M.A. in 1910, but gave up membership when he retired to Wurt in Surrey.

Dr. PHILIP PAINE MURPHY, acting surgical specialist at the Wil Hospital, Aden, who died on April 7, was born in County Wexford on Aug. 23, 1910, the son of a doctor. After graduating in 1932 as M.B., B.Ch. of Trinity College, Dublin, he worked in hospitals in England for two or three years and then joined the Colonial Medical Service in British Somaliland; he was transferred to Aden in 1939. During his service in Aden he carried out at various times the duties of all the higher posts in the medical department. The following are extracts from a colleague's tribute: "Of his many sterling qualities perhaps the most outstanding were his manliness, honesty, sincerity, straightforwardness, and thoroughness. He aimed at perfection in all that he undertook, in work, in play, and in the smallest details of everyday life. He had an inquiring mind, and any new idea that he took up he pursued with great enthusiasm. He was an able surgeon who inspired confidence in his patients. The war years bore especially hard on him, with extra work and shortages of staff, and few would have carried through as he did. The spirit of comradeship that prevailed among the hospital staff—Arab, European, Indian, and Somali—was ample testimony both to his ability as an administrator and to his attractive personality."

Miss ROSA TURNER, L.R.C.P.&S., who died on April 27 at the Royal Free Hospital after a short illness, was the youngest daughter of the late Alfred Turner, of the Manor House, Upper Twickenham, and practised for many years from 87, Gower Street. She studied at the London School of Medicine for

Women and obtained the Scottish triple qualification in 1895. She had been honorary clinical assistant in the venereal disease clinic at the Elizabeth Garrett Anderson Hospital in Euston Road and was for some years visiting medical examiner at the Brentwood Colony and Homes for the Feeble-Minded under the old Metropolitan Asylums Board; she had also been clinical assistant in the V.D. department of the London Hospital and surgeon to the same department at the Bermondsey Hospital and Medical Mission. Dr. Turner joined the B.M.A. in 1898; she was a Fellow of the Royal Society of Medicine and an active member of the Medical Women's Federation.

Dr. ALFRED COLERIDGE, who died on April 28 at Taunton, had practised for many years at Wadebridge, Cornwall. A native of Bristol, he entered the University with a scholarship from Clifton College in 1892, qualified in 1901, and took the M.B., B.S.Lond. in 1905 after holding house appointments at the Bristol General Hospital and at the Mount Vernon Consumption Hospital in Hampstead. He was for four years surgeon to the Bristol Dispensary, and during the war of 1914-18 served as major, R.A.M.C., T.A.; with No. 46 (Wessex) Casualty Clearing Station in France. On returning to civil life he practised in North Cornwall and was appointed M.O.H. by the Wadebridge Urban District Council in 1923. Dr. Coleridge had been a member of the Cornwall Panel Committee and commandant of the Wadebridge Mobile Aid Post in the A.R.P. service.

Medico-Legal

SECRECY IN JUDICIAL PROCEEDINGS

In a divorce action held at Birmingham Assizes at the beginning of April it appeared that one of the parties was said to be suffering from venereal disease and that, in order to simplify the procedure, the doctor treating the party had been sent a questionnaire signed by both the petitioner and the respondent, with the consent of the solicitors on both sides. If the questions had been answered in one way the petitioner would have succeeded, and if in another way the respondent would have succeeded. The doctor had refused to answer the questionnaire though he had said that he would give evidence in court if summoned. He actually gave evidence, and there was no question of his good faith. Mr. Justice Lewis gave an important ruling, which he said had the blessing of Lord Merriman, president of the Divorce Division. It was of the greatest importance, said the learned judge, that appropriate secrecy should be observed in connexion with V.D. clinics, and nothing should be done to diminish their efficiency or infringe the confidential relationship between doctor and patient. This, however, did not justify a doctor in refusing to divulge confidential information to a patient or any named person when asked by the patient to do so. The doctor could in the circumstances have given the information required without any breach of confidence.

This ruling, which will be a valuable guide to doctors in the future, recalls the case of *Garner v. Garner* (1920), in which the wife petitioned for divorce on the grounds of cruelty, alleging that her husband had infected her with venereal disease. She called a medical officer of a hospital to prove that she had the disease. Although she was his patient and therefore had waived the duty of secrecy between doctor and patient, as in the present case the patient waived it by signing the questionnaire, the doctor and the chairman of his house committee took the view that he was bound by the Public Health (Venereal Disease) Regulations, 1916, to maintain secrecy. Mr. Justice McCardie said that the statutory regulations could not override the obligation of a medical witness to give evidence. Mr. Justice Lewis has extended the principle by ruling that they cannot override the doctor's obligation, when asked by his patient, to give a preliminary statement. Although technically there may be a conflict between the wording of the regulations and the demands of justice, the rule of secrecy exists solely in the interests of the patient, and if the patient waives it there can be no further reason for its observance. If the patient does not give consent the situation, of course, is totally different, and the doctor should refuse a preliminary statement and only give evidence in court at the direct order of the judge.

RAYNAUD'S DISEASE AS AN ACCIDENT?

A workman may successfully claim compensation if personal injury by accident arises "out of and in the course of" his employment. These words have caused perhaps more legal argument than any others, partly because of the desire of the court to benefit the workman wherever it possibly can. The result has been that the word "accident" has gradually acquired a meaning considerably wider than it usually has among laymen. Quite early in the history of workmen's compensation the House of Lords decided¹ that a disease such as anthrax may in certain circumstances be compensable, because the entry of a germ into the body may be an accident. The principle was extended in a case² in which the Court of Appeal and later the House of Lords awarded compensation to a girl who had over a long period suffered from slight cuts and abrasions which gradually caused poisoning. That case was followed recently in an appeal³ by a workman who had been employed as a "rotary fitter." He had to cut material with an electrically driven instrument which vibrated at 2,800 revolutions a minute: he held it tight in his left hand and pressed it against the material with his right, using the weight of his body to increase the pressure. After about a year he began to find the tips of the fingers of his left hand going dead in the morning. He showed it twice to the works doctor, but each time he was told it was not a "dead hand." Finally his hand went dead three times in one morning, and he was incapacitated totally for three months and thereafter partially. His own doctor said that he was suffering from Raynaud's disease, due partly to loss of blood in the tissues, which caused the hand to go white, and partly to loss of blood in the nerves causing spasm of the blood vessels. The first cause was an upsetting of the balance of nervous control of the blood vessels due to the tight grasping of a rapidly vibrating instrument, every time the tool was used the condition got worse. The judge accepted the facts, but held that to constitute an injury by accident the workman must be suddenly and decisively attacked at his work, and that the gradual ruining of his blood vessels did not bring him within the Acts. He was influenced by a decision of the Court of Appeal⁴ given 30 years ago against a worker who gradually became poisoned by lead, on the ground that a gradual process could not be an accident. The Court of Appeal has now held that its earlier decision was not in accordance with later decisions of the House of Lords and so ought not to be followed. Guided by these later authorities, the court took the view that each vibration caused by the rapidly rotating instrument was an infinitesimal blow to the man's hand and arm transmitted to the nerves, causing an infinitely small damage to their tissues and in the end cutting off the flow of blood needed to keep the hand in a healthy condition. The mere fact that the breakdown did not occur until the cumulative effect of the tiny blows had produced a certain degree of alteration in the nerves did not, they said, affect the character of the cause. An injury is still caused by accident even though it is due to an infinite number of small accidents and not to one large one.

In making a medical film, up to eighteen months may elapse between the time that preparations are begun and the time that the completed film is available. During this interval someone else may unwittingly have planned another film on the same subject. The Scientific Film Association has undertaken a voluntary co-ordination scheme intended to minimize the possibility of such overlapping. It is suggested that the S.F.A. Medical Committee should be informed confidentially at the inception of a plan to make a new medical film. The committee will then do its best to advise the intending producer of existing films on the subject, and if practicable will arrange a viewing. Where two or more organizations or persons disclose to the committee the same or overlapping subjects for a medical film, the two parties concerned will be informed that others are in the field, but names will not be disclosed. However, if both parties wish for a consultation the committee will arrange this, and will in the case of collaboration as in individual work assist with what technical advice is at its command. Offers of co-operation and any other inquiries should be addressed to the Hon. Secretary, Medical Committee, Scientific Film Association, c/o the Royal Society of Medicine, 1, Wimpole Street London, W.1.

Medical Notes in Parliament

Members of the Standing Committee

To Standing Committee C, for the consideration of the National Health Service Bill, have been added Mr. Bevan, Mr. Willink, Dr. Clitherow, Dr. Comyns, Mr. Somerville Hastings, Mr. Linstead, Dr. Morgan, Sir Henry Morris-Jones, Colonel Stoddart-Scott, Dr. Stephen Taylor, and other members.

HEALTH SERVICE BILL IN COMMITTEE

With Mr F. G. BOWLES in the chair, a Standing Committee of the House of Commons, to which several medical M.P.s had been added, began on May 14 the Committee stage of the National Health Service Bill. Mr. Bevan and Mr. Key were the Ministers in charge of the Bill. Mr. Bevan proposed that the Committee should meet each week on Tuesdays, Wednesdays, and Thursdays. He said this was essential to get the Bill on the Statute Book this session. Mr. Richard Law and Sir Henry Morris-Jones assented to the proposal. Each disclaimed for his friends any intention of obstructing the Bill. The Committee agreed to sit three days a week.

CONSULTATION WITH CENTRAL COUNCIL

In Clause 1, defining the duties of the Minister for promotion of a comprehensive health service, Mr. WILLINK moved to insert:

Provided that in the discharge of the said duty the Minister shall consult with the Central Health Services Council, to be constituted under this Act, and shall have regard to regional schemes to be submitted to him by the Regional Boards to be constituted under this Act for the proper planning and integration of all such services as aforesaid within the areas of such boards.

Mr. Willink said the Opposition wished to raise the status of the Central Health Services Council and the question of the integration of the health services as a whole. The Opposition amendment did both. He pointed out that the amendment referred to Regional Boards, not merely to Regional Hospital Boards. He was sure Mr. Bevan wished to avoid the service being excessively bureaucratic or over-centralized. The service must win and keep the confidence of the medical profession, which was an individualized one, both centrally and locally. The principle of consultative councils had been established in 1919, but there had since been a lack of confidence in the medical profession owing to the absence of adequate consultation between the Ministry and the profession. There had consequently been disappointment in the profession at the progress made by the Ministry of Health. He felt that the Bill, as it stood, was inadequate on the status of the Central Council. Under it the Minister undertook no duty to use the services of the Central Council for any purpose and no obligation to consult them. The status of the Council should be stated in close association with the Minister's main duties in Clause 1.

"PLANNING" THE HOSPITAL SERVICE

Mr. Willink said that the second part of his amendment related to one of the greatest changes made by Mr. Bevan in the previously projected health scheme. The Bill made no provision for the planning of a comprehensive health service. Therefore the amendment introduced the phrase "Regional Boards," leaving the function of these to be defined later. There was not even provision for planning regional hospital services. The Regional Hospital Boards were only to administer what existed. Did the Committee want an extraordinary centralization entrusting to the Minister's staff the planning of all hospital development throughout the country? Surely some body nearer the people in the regions or the area should have a planning function. Moreover, it was essential in a health service that someone should consider how the various parts should fit in. Someone should decide the proportion between specialist beds in hospitals and general practitioner beds. Some authority should decide who should provide V.D. services. Similarly with the health centres, which the White Paper, though not the Bill, said should be outposts of the hospitals. The Bill left these entirely to the local authorities. Croydon had provided an integrated maternity service. Nothing in the Bill ensured that this would be continued or imitated. In mental services the Bill did nothing to decide who should provide after-care. Ophthalmic services fell under two parts, with no authority to see how they fitted together. The White Paper of 1944 said it was essential that, though still locally conducted, health services should be regarded as parts of a wider whole with some authority to plan the whole. It was, he said, disastrous to leave the vital part of the work to a heavily burdened Department.

AMENDMENT RESISTED

Mr. BEVAN said Mr. Willink's speech showed considerable misunderstanding. The Minister would not set up a Central Advisory Council if he did not intend to consult it. That Council had the power of initiative and a much higher status than most advisory councils. It had also the right to publish annual reports so that the public would be apprised of the advice which it had given to the Minister. If the duty were imposed on it of advising the Minister on everything, the Council would be overweighted. It had the power to advise the Minister on subjects about which he had not asked for advice. Mr. Willink's proposal that the Regional Boards should prepare schemes for integration of services would cause the Boards to break down, and years would be needed to harmonize the different unrelated schemes. The responsibility must rest upon the Minister, where Parliament had placed it. Integration of the services would result from the use of the services. In the past the hospital services had been in the hands of competitive bodies, each denying its services to the other, but in future they could not deny them to anyone, and the common use would prove to be the co-ordination. Under the Bill Regional Hospital Boards were to submit new schemes when called upon. The more that was put into the Bill of a defining character the less elastic the service would become. They must beware of making the whole health service muscle-bound. He felt he must resist Mr. Willink's amendment.

Mr. J. S. C. REID considered that the facts on fundamental matters should be brought to the attention of the Central Council before the Minister took decisions. If the Minister took the view that regional schemes must be centrally prepared there would be a sealed pattern in the Ministry. Mr. Bevan thought that because everybody was to be a public servant there would be no rivalry and no difference of view on the extent of their functions. Mr. H. G. STRAUSS said he found no obligation in the Bill that the Minister should consult the central advisory body on every regulation that he proposed to make.

Mr. LINSTAD said the professions concerned were suspicious. If the Minister could renew his assurance that any regulations would be communicated beforehand that would affect the attitude of the professions. Mr. BEVAN replied that there would certainly be such consultation on regulations concerning medical matters. Mr. LINSTAD thought that if that were so the Minister would have the professions with him. On co-ordination he remarked that under the Minister's scheme regional co-ordination would in fact occur through the Minister's regional officers instead of the preferable co-ordination through the representatives of the local health authorities.

The amendment was rejected by 29 to 17. Clause I was carried.

LIMITING THE CENTRAL COUNCIL?

In Clause 2 Mr. LAW moved an amendment to remove a limitation on the Central Council. Its advice to the Minister under the Bill was restricted to general matters. Was the Council unable to advise on particular matters, and if so what were these? Under Clause 2 the Central Council might be barred from advising the Minister on directions to teaching hospitals.

Mr. BEVAN said if the word "general" were deleted the character of the Council would be altered to its own misfortune. The Minister could ask the advice of the Council on any question, but it was inappropriate that a body of 41 persons could submit the whole of the health services to microscopic examination. He added that on subjects such as gynaecology there would be specialized subcommittees to advise him. The reports of these subcommittees would be available to the Central Council as well as to the Minister.

Mr. LINSTAD said the Central Council would not bother itself about detail. Only the expert body could decide whether a point were of general importance. Mr. HOPKIN MORRIS said the Minister would be wise to omit the word "general." The clause said it should be the duty of the Central Council to advise the Minister "as they think fit." Why not trust these responsible men?

Mr. BEVAN said if the Council thought a particular matter required investigation it would advise the Minister to refer it to an expert committee, if one existed, or to set up such a committee for the purpose. But among the people many bees would be buzzing in many bonnets, and the word "general" would be a protection to the chairman of the Council. Mr. WILLINK said the Council should be able to pronounce upon the Minister's decision on the number of rheumatism centres or plastic surgery centres to be established in the country. But that would not be a "general" matter. Under the Bill the Minister could give unlimited directions to the teaching hospitals which, in the opinion of the Central Council, would be disastrous. Yet that would not be a "general" matter.

Mr. BEVAN replied that the Council could advise on any particular service when a standing advisory committee reported on it, because the report would go to the Central Council as well as to the Minister. The Council could advise on each one of the services provided as well as on all the services as a whole. If further examination showed that the language of the clause prevented the Council from reviewing the advice of standing advisory committees he would have the language altered.

In view of this undertaking Mr. LAW withdrew his amendment.

Clause 2 provides that the duty of the Central Council is to advise the Minister upon general matters relating to the services provided under the Act. Sir H. MORRIS-JONES moved to delete "services" and the words following, and to substitute "purposes of this Act defined in Section 1." Mr. WILLINK thought that for years to come many medical services would not be provided under the Bill.

The CHAIRMAN ruled the amendment out.

POWER TO ALTER CONSTITUTION OF COUNCIL

Mr. H. STRAUSS moved to omit the provision that the Minister could, after consultation with the Central Council, vary by Order the constitution of the Council. He said this power was unlimited and dangerous. Mr. BEVAN said he had no sinister intentions. The subsection was for the purpose of practical administration. When the Midwives Board was set up the Board could not be varied in its constitution save by Act of Parliament, and difficulties had followed. He recognized that the Central Council might feel it was living under a threat of replacement. Therefore he was prepared to move, on report, a provision that the Council should be consulted on changes and that the Order should be subject to a negative resolution of the House. Sir HAROLD WEBB said the balance in the Council was delicate, and there was anxiety lest it should be upset. Mr. STRAUSS withdrew his amendment.

Mr. LINSTAD moved amendments to ensure that certain standing advisory committees were named in the Bill. He proposed to specify the hospital and specialist services, the general medical services, the dental services, the nursing services, and the pharmaceutical services. Mr. BEVAN said the amendment was unnecessary. Spokesmen of ancillary medical services wished to have standing advisory committees. He sympathized, but could not agree. Moreover, an advisory committee, if named in the Bill, could not be dissolved if circumstances changed. Mr. WILLINK said not only small interests wished to have the statute clear on this point. The White Paper did not specify a standing advisory committee at the centre on hospital organizations. In the Central Council only 5 persons out of 41 must have experience in hospital service. Only 2 out of 41 must have experience in mental health.

The amendment was rejected by 30 to 15 and the Committee adjourned.

Spens Report

Replying to Mr. Somerville Hastings on May 9, Mr. BEVAN said the report of the Spens Committee on the Remuneration of General Practitioners had been published that day. He had not reached a decision as to its implementation. He would have to have discussions with the representatives of the doctors before he reached any decision on the report.

Student Entry to Universities

Answering questions on April 30 Mr. GEORGE ISAACS said that the following decisions had been made about the entry of students to the universities for the year beginning October, 1946: (1) Preference would be given to men who had served in the Armed Forces and others who had been engaged for an equivalent period in important civilian work, provided they were suitable for acceptance by the university concerned; (2) places in all subjects at universities should be filled; (3) any young men still liable to be called up for military service who were granted deferment to enable them to study at a university would be called up on the completion of their course. It would be open to the universities to apply for release in Class B of scholars and highly promising students in any subject who were still serving in the Forces and were in release groups 1 to 55. The universities might also admit students with similar qualifications who had completed three years' work of national importance by Sept. 1, 1946, and such students would be granted continued deferment of their calling-up to enable them to complete their studies.

After the requirements of men in (1) above had been satisfied any remaining places in any subject might be filled by promising students in the age group Oct. 1, 1927, to Sept. 30, 1928, who were recommended for deferment by Joint Recruiting Boards. Any university, however, could make out a special case for reserving places for such students where their accept-

ance meant the exclusion of the older men. These arrangements involved a change for medical, dental, and veterinary students. These had hitherto been reserved; in future new entrants would be dealt with in the same way as other students, and would have to be considered individually for deferment by Joint Recruiting Boards. Mr. ISAACS said he was asking universities to give preference at women's colleges to those women who had been engaged on war service, and, where women competed with men, to limit the women entrants from school to those of exceptional promise.

The number of young men who could be deferred could not be determined until they knew the number of applications coming from ex-Service men. This meant a period of uncertainty which could not be avoided, and acceptances by universities of men in the age group Oct. 1, 1927, to Sept. 30, 1928, must be regarded as provisional.

Atomic Energy Bill

The Atomic Energy Bill was read a first time in the House of Commons on May 1. The Bill provides that the restriction proposed on disclosure of information relating to plant for the purpose of producing or using atomic energy shall not include references to plant designed to be used solely for scientific research or education.

Kenya Medical Service

Mr. BOWLES asked on May 1 whether the Secretary for the Colonies knew that resident Kenya medical officers, on release from the Army, were denied Government appointments, some of which were held by Italians. Mr. GEORGE HALL replied that he was aware of only one case during the war in which an applicant who was a serving military or ex-military medical officer had been refused a permanent appointment in Kenya. He was not considered suitable on account of his age, but had since been given a post under the Kenya Pensions Assessment Board. Four Italian doctors were at present employed on a purely temporary basis, but would be replaced as soon as suitable candidates were available. Several Kenya residents with medical qualifications were also employed as temporary medical officers. Mr. BOWLES said he had information that Italian medical men were taking the places of medical men who had been resident in Kenya.

Deaf Aid

Mr. BURKE, in a debate on Post Office research on May 3, said the Post Office had just been successful, in association with the Medical Research Council, in bringing out an ear aid which would benefit thousands of deaf people in this country.

Diphtheria Incidence and Deaths

On May 6 Mr. VIVANT asked the Minister of Health how many cases of diphtheria were recorded in England and Wales in 1945; how many of these proved fatal; what were the patients' ages; and how many in both fatal and non-fatal cases had been immunized.

Mr. BEVAN said the number of cases of diphtheria notified in 1945 was 18,571. The number of deaths notified in 1945 was 720, this figure being provisional. The ages in the cases notified and in fatal cases were as follows:

Age	Notifications	Deaths
0- ..	188	18
1- ..	1,486	113
2- ..	2,001	120
3- ..	5,948	257
4- ..	3,467	74
5- ..	3,330	45
10- ..	2,421	93
15- ..	130	0
25 and over	130	0
Unknown	130	0
Total ..	18,571	720

Information about cases of and deaths from diphtheria in relation to immunized children for the year 1945 was not yet available.

Mr. WESTWOOD furnished the following table of cases of diphtheria recorded in Scotland in 1945:

Age Group	Cases		Deaths	
	Immunized	Non-immunized	Immunized	Non-immunized
0-4 ..	267	1,175	1	76
5-14 ..	1,104	1,151	5	29
15 and over	153	810	-	15
Totals ..	1,524	3,136	6	120

Analgesia in Childbirth

Mr. MIKARDO inquired on May 2 how Mr. Bevan proposed to make universal the use of apparatus and techniques designed to reduce or eliminate pain in childbirth. Mr. BEVAN said administration of gas-and-air analgesia in childbirth could not become universal until there was an adequate supply of apparatus and of midwives trained to use it. The production of apparatus had already been increased, and all pupil midwives beginning Part II of their course on and after July 1 next would be trained in its use. No practicable step would be neglected, but until more women could be attracted to the practice of midwifery progress was bound to be slow. He promised to investigate the use of the triline apparatus.

Notes in Brief

The number of deaths from cancer in England and Wales during 1945 was 73,754, this represents a crude death rate of 1.945 per million living. These figures are provisional and relate only to civilians. In 1944 21,571 experiments were performed on living animals in connexion with cancer research. The figure for 1945 is not yet available.

Of 749 men and women employed in the Department of Health for Scotland on April 1, 1946, 23 possessed medical degrees. These figures do not include staff employed in the Department's emergency hospitals.

Only one case of smallpox has been notified in Scotland this year in the person of an Army officer returning on a troopship from India.

The Minister of Supply is not aware of any general shortage of rectifying valves for deep x-ray therapy apparatus, although there is difficulty in obtaining replacements for apparatus of German origin.

The Services

Surgeon Rear-Admiral H. M. Whelan has been appointed an Honorary Surgeon to the King in succession to Surgeon Rear-Admiral A. Maclean, C.B., D.S.O., deceased; and Surgeon Rear-Admirals A. E. Malone, C.B., and J. O'Flynn have been appointed Honorary Physicians to the King in succession to Surgeon Rear-Admirals Sir Reginald Bankart, K.C.V.O., K.H.P., deceased, and J. F. Hole, C.M.G., deceased, respectively.

Air Vice-Marshal K. Biggs, C.B.E., M.C., has been appointed Honorary Physician to the King in succession to Air Marshal Sir Harold E. Whittingham, K.C.B., K.B.E., who has vacated the appointment on retirement from the R.A.F.

Surg. Lieut.-Cmdrs. R. T. Jones and H. R. Vickers, R.N.V.R., have been awarded the R.N.V.R. Officers' Decoration.

The Efficiency Decoration of the Territorial Army has been conferred upon the following officers: Lieut.-Col. (Temp. Col.) R. H. Robinson, Lieut.-Col. T. H. Wilson, Majors (Temp. Lieut.-Cols.) F. R. Bettley and A. S. L. Malcolm (T.A.R.O.), Majors E. Davies-Thomas, R. W. Gemmell, and F. S. Mitchell-Heggs, and Capt. (Temp. Major) F. J. Whitelaw, R.A.M.C.

Subadar K. S. Gupta, I.A.M.C., has been appointed M.B.E. (Military Division) in recognition of gallant and distinguished services while a prisoner of war.

The following have been mentioned in dispatches in recognition of gallant and distinguished services in Burma:

Brian (Temp. Col.) J. C. M. DSO, MC, and N. T. Menzies, C.B.E. Col. (Temp.) J. P. W. Hannay, P. W. Hannay, H. Morris, W. I. G. H. Waters, Lieut.-Col. (Act. D. Billig, N. H. McK. Couper, T. Fitt, L. A. I. H. C. Page, W. J. Major (Acting) Chase, D. H. (J. J. Phillips, G. and R. L. Wit. N. Slater, R.A. Col. (Acting) V.

Lieuts. C. L. Nagrah, C. R. S. P. K. Tamaskar, and S. C. Sen; I. Khan, K. C. Bedi, K. Lal, N. Nath, N. Singh, and T. Singh; Jemadars A. A. Khan, B. Bux, M. Singh, M. T. Hussain, N. Ram, B. D. Pandey, and S. R. Shah, I.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

Died at sea.—Major Colin Campion, R.A.M.C.

Died in India.—Lieut.-Col. Gilbert Wolridge Rose, R.A.M.C.

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation held on May 2 the following degrees were conferred:

D M.—J. F. Loutit, J. N. Mills (in absence)
B M., B Ch.—M. B. McEvedy, T. H. S. Burns

UNIVERSITY OF CAMBRIDGE

At a Congregation held on May 3 the following medical degrees were conferred, all by proxy except one marked with an asterisk:

MD—A. G. V. Aldridge, *G. C. Tooth.
MB, B Chir.—R. W. P. Jackson, B. A. J. C. Gregory, R. N. Grabowsky-Atherstone, P. N. Magee
MB—R. G. Orr.

A report by the Council of the Senate on the establishment of a chair of pharmacology appears in the *Cambridge University Reporter* of May 7 (p. 777). This recommends that there be established from Oct 1, 1946, a Shield Professorship of Pharmacology limited to one tenure, and that the professor be E. B. Verney, MA, MB, B Chir, whose readership in that subject would then lapse.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At an ordinary meeting of the Council, held on May 9, with Sir Alfred Webb-Johnson, Bt, President, in the chair, Prof. R. V. Bradlaw was re-elected a member of the Board of Examiners in Dental Surgery.

It was decided, subject to the grant of the necessary powers, to establish a Faculty of Dental Surgery in the College.

Dr. G. M. Vevers and Dr. A. J. Durden Smith were admitted as fellows of the College.

The Walker Prize was presented to Prof. E. C. Dodds; the John Hunter Medal and Triennial Prize to Dr. Joan Ross; and the Begley Prize to Mr. Otto Fleischer.

The Council accepted the trusteeship of the Cecil Joll Memorial Fund, under which there will be awarded a triennial prize for some surgical subject.

The Chase Farm Hospital, Enfield, the Seamen's Hospital, Tilbury, and the Broad Green Hospital, Liverpool, were recognized in respect of the resident surgical post required of the candidates for the Final Fellowship Examination.

Diplomas of membership were granted, jointly with the Royal College of Physicians of London, to J. R. Handforth and to the 125 successful candidates whose names were printed in the report of the meeting of the Royal College of Physicians of London in the *Journal* of May 4 (p. 704); as were the names of the successful candidates for the diplomas in medical radiodiagnosis and medical radiotherapy.

EPIDEMIOLOGICAL NOTES

Discussion of Table *

In England and Wales an increase was recorded in measles 401, diphtheria 62, while the notifications of both whooping-cough and dysentery fell by 26.

The largest variations in the local trend of scarlet fever were an increase in London 20 and a decrease in Glamorganshire 20. The returns for diphtheria showed the smallest total for 34 weeks. Whooping-cough was slightly more prevalent in most districts, the largest rise was Glamorganshire 33, and the chief exceptions to the general trend were decreases in London 38 and Middlesex 32. Measles is still mainly concentrated in London and the surrounding counties, and the largest rises were London 119, Essex 66, Middlesex 56, Kent 41, and Warwickshire 41.

The notifications of dysentery were the lowest for 16 months. The chief centres of infection were Lancashire 28, London 25, Staffordshire 14, Kent 13, and Surrey 10.

In Scotland increases were recorded for acute primary pneumonia 51, diphtheria 24, and scarlet fever 19; decreases were shown for measles 105 and whooping-cough 15. The incidence of dysentery remained unchanged. The rise in cases of diphtheria was contributed by Glasgow, where the figures rose from 32 to 55.

In Eire the incidence of diarrhoea and enteritis increased by 20 and reverted to the level of the preceding weeks. Increases were also reported for scarlet fever 17 and whooping-cough 11.

In Northern Ireland scarlet fever fell by 21 cases.

Week Ending May 4

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 945, whooping-cough 2,147, diphtheria 367, measles 2,711, acute pneumonia 610, cerebrospinal fever 58, dysentery 212, paratyphoid 6, typhoid 5.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 27

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included) (b) London (administrative county) (c) Scotland. (d) Eire. (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the return are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

Medical News

The Nutrition Society will hold a conference on Saturday, May 18, at 2 p.m. at the London School of Hygiene and Tropical Medicine, Keppel Street, London W.C.1. This follows the annual general meeting of the English Group which is to be held there on the same morning at 11 a.m. The programme and time table are as follows: Lt-Col J. Bennet will read a paper on nutritional conditions in Army prison camps in the Far East; Dr D. A. Smith will speak on experiences in the civilian camp at Hong Kong; and Prof. R. G. Scott MacGregor on similar experiences in Singapore. Dr R. C. Burgess and Dr E. K. Cruickshank will deal with conditions in the military camp at Singapore, and Dr Cicely Williams with nutritional conditions among women and children. The opening of the discussion will be Dr J. V. Landor. Non-members are admitted to meetings of the Society by the introduction of a member. Meetings are private, and no unauthorized account may appear in the press. Further details of the Nutrition Society can be obtained from the hon. secretary, Dr Leslie J. Harris, Nutritional Laboratory, Cambridge.

At a meeting of the Colour Group of the Physical Society to be held at 3.30 p.m. on Thursday, May 23, in the lecture room of the Royal Photographic Society, 16 Prince's Gate, Kensington, S.W., a paper on "The Colour Sensitivity of the Retina within the Central Fovea of Man" will be presented by Dr L. C. Thomson and Dr W. D. Wright, and will be followed by an informal discussion.

At a meeting of the Medical Group of the Royal Photographic Society to be held at 16, Prince's Gate, London, S.W. 7, on Thursday, May 23, at 6.30 p.m., Miss Sylvia Treadgold, Mr Victor Willmott, Mr Norman K. Harrison, and Dr B. Richardson Billings will give short papers on "Methods in Medical Photography," with illustrations. A discussion will follow.

At a meeting of the Medical Legal Society to be held at 26 Port Land Place, W., on Thursday, May 23, at 8.15 p.m., the president Dr W. Norwood East, will read a paper on "Crime and Maturity."

A meeting of the Middlesex County Medical Society will be held at St. Shewell Hospital on Saturday, May 25, at 3 p.m.

The forty-seventh annual meeting of the Association of Port Health Authorities of the British Isles will be held in the City Chambers, High Street, Edinburgh, on May 28, 29, and 30. Among the papers to be read are one by Dr M. T. Morgan M.O.H., Port of London, on some aspects of the control of smallpox, and another by Dr W. P. Cargill on developments in disinfection. The honorary secretary of the Association is Dr H. C. Maurice Williams, Health Department, Civic Centre, Southampton.

A general meeting of the Heberden Society will be held at the Medical Society of London (11, Chandos Street, W.) on Friday, May 31, at 5.30 p.m., when Mr H. Jackson Burrows and Dr George Graham will present a paper on "Spinal Osteoporosis of Unknown Origin."

Dr L. Alice Hamar has been elected a county councillor for Salop. Dr Aubrey Ireland has been re-elected as county alderman for Salop and chairman of the Mental Deficiency Committee; he has also been elected chairman of the West Midland Joint Board for Mental Deficiency.

The Medical Women's Federation will award, in the autumn, either two grants (one of £50 and one of £25) or one grant (of £75) from its Christine Murrell Postgraduate Fellowship Fund. Applications are invited from women general practitioners, who must be members of the Federation. Age, qualifications, experience, and some indication of the use to which the grant would be put should be stated. Applications must be received not later than Aug. 31, and should be addressed to the Secretary, 73, Bourne Way, Hayes, Bromley, Kent.

For the delegations of seven Belgian and six French surgeons who attended the conference of the Association of Surgeons in London the British Council has arranged a provincial tour to Manchester, Oxford, and Edinburgh. They are visiting hospitals and other medical institutions under arrangements made by Prof. H. Platt, University of Manchester, Prof. Hugh Cairns, University of Oxford, and Prof. J. R. Learmonth, University of Edinburgh.

The Treasury has made an Order the effect of which is to exempt from Purchase Tax batteries of not less than 15 volts and not more than 45 volts specially designed for high tension supply for deaf-aid appliances and using layer type cells not exceeding 6 mm in thickness with zinc elements of which each face does not exceed 500 sq mm. The exemption applies only to goods which are delivered on sale, or appropriated to retail trade or similar purposes, on or after May 20, 1946, or, in the case of imported goods, which are entered with the Customs or delivered from bonded warehouse for home consumption on or after that date.

Sir Howard Florey, F.R.S., is visiting France under the auspices of the British Council from May 18 to 25 to lecture on penicillin and allied subjects in Lyons, where he will receive an honorary degree, and Paris.

The Rockefeller Foundation has made a grant of £22,000 to develop practical work in such problems as industrial relations, resettlement of returning Service men, and the current difficulties of families and communities in the reconstruction period. Two anonymous donors have added £3,500 to this fund. The work will be undertaken by a group of psychiatrists and psychologists with wartime experience in the field of social psychology, and will form the main task of a new organization, the Tavistock Institute of Human Relations, whose formation is being planned by the Council of the Tavistock Clinic, London.

The Cardiff Public Health Committee has planned a Health and Housing Exhibition to be held in the City Hall from June 17 to 22, and the set up is full of interest. There will be 10 bays in the large assembly room representing health through the home, school, recreation, nutrition, personal hygiene, housing, community, careers, port, and knowledge. In two large rooms adjoining the main hall will be exhibits of hospital services for mental and bodily health. All who are interested in the possibilities of health education are invited to visit the exhibition at Cardiff and while there to discuss the subject with the specialists in charge of each bay. The medical officer of health for Cardiff, Dr J. Greenwood Wilson, is organizing the exhibits and a detailed programme will be sent on application to the Public Relations Officer, 52, Park Place, Cardiff.

The British Association of Urological Surgeons Home and Overseas will hold its annual general meeting at the Royal College of Surgeons on June 27, 28, and 29. The business meeting is arranged for the first day from 4 p.m. On June 28, at 10 a.m., the president, Mr Ogier Ward, will open a discussion on the treatment of benign enlargement of the prostate, and the afternoon will be devoted to operating sessions at several hospitals. There will be a demonstration of films of urological interest on Saturday, June 29. Further particulars and tickets for lunch and dinner at the College on June 28 can be obtained from the secretary at 45, Lincoln's Inn Fields, W.C.2.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, London, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: ARICLAE. All letters sent to the Editor should be accompanied by a return address. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the British Medical Journal, unless the contrary be stated.

Authors of REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: ARICLAE & WESTCENT, London.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 2111. TELEGRAMS: MEDICARE & WESTCENT, London.

B.M.A. SCOTTISH OFFICE: 7 Drumshush Gables, Edinburgh.

ANY QUESTIONS?

Closed Circle in Malaria

Q.—The malaria parasite spends part of its life in man and part in the mosquito. How did it get into this apparently closed circle in the first instance?

A.—This question might be asked of a number of other parasites which have a specialized life-cycle involving two quite different hosts. The answer is not known, but presumably the plasmodium was originally a parasite of either the mosquito or of man, and a mutation occurred which enabled it to propagate more successfully by the complex two host arrangement that exists now. There are, of course, other protozoa, both in man and in the mosquito, which do not cause disease but which, presumably, might evolve into pathogenic types.

Thiouracil for Thyrotoxicosis

Q.—What is the correct mode of administration of thiouracil, and is it wise for a doctor who has no experience of the drug to prescribe it?

A.—Thiouracil is usually given in a dosage of 0.6 g daily, though it is probable that smaller doses are as, or almost as, effective. This dose is continued until a definite response is obtained, the criteria of response being general improvement,

increase in weight, fall in pulse rate, loss of vasodilatation, and fall in B.M.R. Where the apparatus is not available the last is not essential. After response the dose is reduced to 0.2 g. daily. After a few months it is often possible to reduce the dose to 0.1 g. daily, and eventually, in a few patients, it may be discontinued. There is only one serious danger—that of agranulocytosis. Most of the reported cases occurred with a higher dosage than that which is now used. Nevertheless, a white cell count should be done every other day while the initial dose is being administered. A drop below 5,000 per c.mm. should be a signal for stopping the drug, and a continued drop, or symptoms of agranulocytosis, should be treated immediately with pentose nucleotide and liver injections (both of doubtful value) and blood transfusion.

Lest this should seem rather frightening advice, I would add that I have never seen a case of agranulocytosis due to thiouracil, and that since the original high dosage was dropped I have not seen one of even granulopenia. More common but less serious complications, which may be neglected provided that a watch is kept on the white cells, are skin rashes, conjunctivitis, nausea, and depression. It is possible to overdo it and produce hypothyroidism, but this is evidence of carelessness, and anyhow it clears up when the drug is discontinued.

If proper care is exercised there is nothing against the use of thiouracil by those who have no experience of the drug provided they have experience of the disease. There are, however, circumstances in which surgery is still indicated. Thiouracil should not be used if the goitre is very large, because the treatment does not reduce its size and may even (though probably only in excessive dosage) increase it. For the same reason it should not be used if there is any evidence of pressure on neighbouring structures or if the goitre is retrosternal.

Phytic Acid in Oatmeal and Bran

Q.—*The regular ingestion of oatmeal is said to have a rachitogenic effect because of its large content of phytic acid. Is this also true of bran?*

A.—Wheat contains as much phytic acid as oats, and this phytic acid is largely concentrated in the bran and germ. Bran is therefore exceedingly rich in phytic acid. Wheat products, however, are on the whole less prejudicial to calcium absorption than similar preparations made from oats, because wheat contains an enzyme—phytase—which may destroy part of the phytic acid during the manufacturing or baking processes. Nevertheless, bran will probably do more to prevent the absorption of calcium from the gut than an equal weight of oatmeal. Neither bran nor oatmeal will deplete the body of calcium if the diet contains plenty of milk and cheese.

Legal Responsibility for Negligence

Q.—*A dermatologist prescribes a correct dose of x rays for a patient who is then treated by a technician in an x-ray department controlled by a radiologist. If through an error on the part of the technician a patient is damaged by the x rays, who carries the responsibility—the dermatologist or the radiologist?*

A.—The dermatologist presumably carries no liability, for he has not himself been negligent and is not in control of the technician, who is therefore neither his servant nor his agent. The liability of the radiologist depends on the degree of control he was in duty bound to exercise. If he had good reason to suppose that the technician was competent to give the treatment without supervision, and if to do so was the technician's duty according to recognized medical practice, then the radiologist is not liable. If, however, special circumstances existed which made it reasonably necessary for the radiologist to supervise or control in some way the actual giving of the treatment by the technician—for example, if the treatment were especially difficult or the technician relatively inexperienced—then the radiologist might be held to have been negligent, but the action would be founded on the radiologist's personal negligence rather than on his liability for that of the technician.

Medical auxiliaries employed in hospital departments are recognized as fully competent to do the work allotted to them, and would only rarely, if at all, be regarded as the servants or agents of the medical chiefs of the departments. Their negligence can, however, be visited upon the hospital authorities who employ them, for they are the servants or agents of the

hospital. The questioner is advised to read the full judgments in the case of *Gold v. Essex County Council (All England Reports, 1942, 2, 237)*, in which the facts were similar. It is significant that in that case the plaintiffs did not allege that the radiologist, still less the dermatologist, was in any way responsible for the negligence of the radiographer in giving treatment for a skin complaint. Lord Justice MacKinnon indicated in passing, purely by way of illustration, that if the radiographer had been merely doing something which the dermatologist had told him to do, and as he told him to do it, the dermatologist would be liable. Such circumstances, however, are probably rare in hospital practice.

Inheritance of Otosclerosis

Q.—*What advice would you give a young woman of 25 suffering from otosclerosis and anxious to marry? The deafness is severe; with an electrical device she can hear general conversation with difficulty. What are the chances of inheritance of the disease? Her future husband's family history is clear. Her own father was deaf, but the nature of the deafness was never diagnosed.*

A.—It is well known that during pregnancy and after childbirth the deafness of otosclerosis sometimes increases, but this happens in an erratic fashion, not only generally but also individually. That is to say, a woman may suffer no further loss of hearing from one pregnancy but may be decidedly affected for the worse by another. This pregnancy factor has therefore probably been overestimated, though the patient should certainly be made aware of it, as also of the possibility of transmitting the defect, so the history on the male side must receive consideration. It is evident that if the hearing becomes worse it will also be worse even when the hearing aid is in use. If the patient wishes to marry she should not be discouraged from doing so on her own account, but the risk of transmitting the defect to offspring is not entirely her own affair.

Otosclerosis is often due to a dominant gene, though its expression is sometimes irregular—i.e., a generation is skipped. Some affected persons, however, have no affected relatives. It may be that in them some non-genetic error of development is responsible. Instances are in fact known in which what appears to be the same end-result is due sometimes to an abnormal gene, sometimes to environmental causes. Thus, the crucial point about the question is whether the patient's father did indeed suffer from otosclerosis. One wishes that more were known about him. If there is nothing in his known history inconsistent with otosclerosis, then in view of his daughter's condition it seems probable that he was affected. If so, inheritance will be dominant and the chance that any child of the patient will also carry the gene is one in two. A child bearing the gene would usually, though not inevitably, develop otosclerosis. One would also like to know more about the family history, in particular about the brothers and sisters both of the patient and of her father. If there were large numbers of these, all normal, the genetic prognosis might be improved.

Thrombo-angiitis Obliterans

Q.—*What is the most effective treatment for thrombo-angiitis obliterans?*

A.—There is no really effective treatment. The position is that no certain measures are known of avoiding further arterial and venous occlusions, though it is commonly agreed that tobacco should be given up. It is also agreed that symptomatic improvement may be produced by measures designed to increase the blood-flow to the limb and to open up collateral vessels—such as sympathectomy and the use of intermittent venous occlusion.

Tremor and Pain in Paralysis Agitans

Q.—*Can anything be done to relieve increasing tremor and pain in an early case of paralysis agitans?*

A.—In paralysis agitans tremor is generally the most intractable of the symptoms, and patients are usually best advised to reconcile themselves philosophically to its existence. The common medicinal remedies (atropine, stramonium, hyoscine) are more efficacious in helping the rigidity, the feelings of tension, and the reluctance to move. Very large amounts may

produce a slight and temporary inhibition of the tremor, but such large doses are rarely justifiable, especially in a disease which is progressive.

Pain is not a common symptom in paralysis agitans; it is most often due to stiffness and to adhesions forming around the joints, and in such cases will be relieved by massage, passive movements, radiant heat, and hot baths. Rarely "thalamie" or "central" pain occurs in paralysis agitans, and proves most intractable; gelsemium is worth a trial, however.

Endometriosis

Q.—A woman of 35, with two children, has pain in both iliac fossae, more severe during menstruation, and has been diagnosed as a case of endometriosis. Should she be treated by operation, by x-ray therapy, or by radium?

A.—As a general rule surgery takes precedence over x rays and radium in the treatment of endometriosis. In the first place, the diagnosis can rarely be made for certain without laparotomy. In particular, it is often difficult to exclude chronic pelvic infection, and the application of radiotherapy to such a case might have unfortunate results. Secondly, in young women treatment short of ablation of ovarian function should be the aim. At operation local excision of the growth or the greater part of it is often found possible. Even when the removal is incomplete and ovarian function is conserved the results can be surprisingly good. When the condition is extensive and conservative measures are out of the question, surgical treatment remains preferable, since it offers the means not only of destroying ovarian function but of dealing with the dense adhesions and the displacement of pelvic organs. These latter remain after radiotherapy and may continue to cause discomfort.

The chief indication for deep x-ray therapy is to suppress ovarian function in those cases in which symptoms recur after a conservative operation—that is, when the diagnosis has been made for certain and when the gross manifestations of the disease have been dealt with. Radium inserted into the uterus is a less efficient means of destroying ovarian function, but it is occasionally used for the direct destruction of an accessible endometriomatous growth, such as one situated in the recto-vaginal septum.

In the case quoted, and on the evidence submitted, the diagnosis of endometriosis is by no means certain. The multiparity of the patient is rather against it. If she does suffer from endometriosis it might be worth while delaying active treatment in the hope that she will conceive again. She may have to wait some time for this, because low fertility is almost invariably associated with endometriosis, but if she succeeds in becoming pregnant spontaneous cure is to be expected.

Hormone Effects on Electrolytes

Q.—Parathormone increases the excretion of phosphate ion. Cortin reduces the excretion of sodium. Posterior pituitary extract not only corrects the polyuria of diabetes insipidus but also the hyperchloraemia which may be present in this condition. Are these effects brought about by an action on the renal tubules, or are they secondary to changes in the metabolism of electrolytes?

A.—If the questioner means to ask whether the changes in concentration of urinary electrolytes result from changes in the concentration of these electrolytes in blood plasma, the answer is clearly No, because in the first two matters cited in the question the changes in urinary concentration are certainly the inverse of those in the blood plasma. It is probable that parathyroid extract acts directly on bone, since it is effective in the absence of the kidneys (H. Selye, *Arch. Pathol.*, 1942, 34, 625; T. H. Ingalls, G. Donaldson, and F. Albright, *J. clin. Invest.*, 1943, 22, 603; H. C. Stoerk, *Proc. Soc. exp. Biol.*, N.Y., 1943, 54, 50), but, as it produces an immediate increase in the urinary excretion of phosphate (W. R. Tweedy and W. W. Campbell, *J. biol. Chem.*, 1944, 154, 339), it is possible that it acts also on the kidney tubules. Nevertheless, when parathyroid extract is given together with phosphate, no influence of the extract on the clearance of inorganic phosphate can be observed (M. Fay, V. G. Behrmann, and D. M. Buck, *Amer. J. Physiol.*, 1942, 136, 716). In the latter experiments a possible complicating factor is the administered inorganic phosphate.

Desoxycorticosterone acetate increases serum sodium and chloride concentrations as well as increasing the plasma volume in normal dogs (M. Clinton, jun., G. W. Thorn, H. Eisenberg, and K. E. Stein, *Endocrinol.*, 1942, 31, 578), and it seems extremely probable that this results at least in part from a direct action on the kidney. Nevertheless, the influence of adrenal cortical hormones on electrolyte metabolism in muscle cells is clearly an important one (cf. D. M. Harkness, E. Muntwyler, F. R. Mautz, and R. C. Mellors, *J. Lab. clin. Med.*, 1942, 28, 307). As the result of their investigations in normal dogs and in dogs suffering from diabetes insipidus, Hare and his colleagues (*Amer. J. Physiol.*, 1943, 140, 334) conclude that "for the regulation of water exchange there is a system which includes the hypothalamico-hypophyseal mechanism, which, through its sensitivity to changes in the salt content of the blood, controls the secretion of pituitrin, and thereby the concentration in which salt is reabsorbed by the renal tubules back into the blood." Nevertheless, they conclude that the factors which determine the partition of chloride between tubular reabsorbate and urine "are not revealed."

In general, it may well be that the influence of these hormones on kidney excretion is a particular aspect of their general action on the electrolyte metabolism of the body as a whole, but although there is no evidence that either the general action or the action on urinary excretion is primary, there is more reason to consider the possibility that the influences on the body in general are secondary to the action on urinary excretion, rather than the converse.

Chemical Prophylaxis of Venereal Disease

Q.—Can you give me information about recent views on the chemical prophylaxis of venereal disease?

A.—Sulphadiazine has proved very effective in the prevention of gonorrhoea and chancroid, particularly in the American Forces. The dose is 2 g. by mouth as soon after exposure as possible, some recommend, in addition, 2 g. next morning, and a similar dose four hours or so later.

Calomel ointment is effective against syphilis if employed early, recent work has shown that particle size is important. Thus, calomel containing particles of 100 microns protected only 2 of 39 rabbits infected with *Spirochaeta pallida*, whilst that of 5 μ protected 9 out of 40, and that of 1 μ 15 out of 40. A good deal of work on chemical prophylactics has been carried out in America during the war, especially on arsenicals, but as the reports are "restricted" it is not possible to give the results. The British Army prophylactic cream, containing oxyzanide of mercury and calomel, is effective if used early enough; soap and water also appears to be effective against syphilis and gonorrhoea, but much less so against chancroid. With any form of chemical prophylaxis the time element and thoroughness of application are the most important factors.

INCOME TAX

Payments in Lieu of Residence, etc.

"DEMobilized" ask whether such payments are liable to tax, and suggest that if so the taxation is "most unjust."

* Such payments are liable. In this connection it should be remembered that with few exceptions taxpayers have to meet the cost of the accommodation and board of themselves and their families out of the net amount left after payment of income tax on their earnings. The exception is that quite small class of taxpayers who receive accommodation, etc., in kind as part of their emoluments. Legislation would be necessary to alter the present state of the law, and it might perhaps be more likely to take the form of making such emoluments liable to tax than that of exempting such portions of emoluments as are expended on the accommodation, etc., of the taxpayer.

Service in India

"HEPAR" served in India from Jan. 1, 1944, to Feb. 25, 1946; he married there and has now returned to the United Kingdom.

* Broadly speaking, liability to British tax on Indian Army pay depends on whether the individual has, while abroad, a residence available for his use in this country. As "Hepar" (unlike the other officer to whom he refers) apparently had no such residence in this country while he was abroad, he is not liable on his Indian pay. If he had such a residence he would be liable on the amount of his remittances to the United Kingdom.

Tax on Colonial Pension

A. N. is in receipt of a pension from which the Crown Agents deduct both British and Colonial tax.

* We suggest that he write to the Chief Inspector, Departmental Claims Branch, the Hydro, Llandudno, Caernarvonshire, stating the facts, and asking for the Dominion income tax relief due to him for the past years.

Depreciation Allowance

G. W. asks: "What depreciation allowance can be claimed for a car used for professional purposes?"

* The normal allowance for the current financial year will be 25% (i.e., 20% plus an additional one-fourth), calculated on the written-down value of the car in use at the end of the year (prior to April 5, 1946) to which the professional account has been made up.

Forces Pay—Dominion National

L. W. completes his 56 days' demobilization leave in June, 1946. He has already returned to South Africa and, presumably, has retained no residential rights in this country. What United Kingdom tax is deductible from his U.K. pay for 1946-7?

* Pay issued from United Kingdom sources is taxable irrespective of the residence of the recipient. The tax for 1946-7, therefore, will be calculated on the basis that a full year's personal allowance is deductible from the amount of income liable to assessment. As the "office or employment" has terminated the pay can be reckoned on the 1946-7 amount.

LETTERS, NOTES, ETC.**Treatment for Sprue**

Dr. H. C. SAKSENA (Preston, Lancs) writes: I should be interested to hear about any cases of sprue which have not responded to usual treatment (resistant cases) and in which the condition is getting worse. I have been trying a new method of treatment which has given extremely satisfactory results, but I haven't had enough cases yet to publish the results and method of treatment.

Preventing Orchitis in Mumps

Dr. Y. G. SOFER (Edgware) writes: Can any prophylactic measures be taken at the onset of mumps to prevent orchitis? (April 27, p. 670). May I refer to the investigation done by McGuinness, Aims, and Peters Michael (*Amer. J. med. Sci.*, 1945, 210, 661) where 20 ml. of gamma-globulin prepared from mumps convalescent serum one to three months after recovery from mumps was given intramuscularly to patients with mumps whose glandular swelling had been present for twenty-four hours. Patients who complained of testicular ache at the time of admission were excluded. The results were as follows:

		No. of Patients who Developed Orchitis	
No. of injected patients	51	4	7.8%
No. of controls	51	14	27.8%

Gamma-globulin from normal human plasma employed in a similar investigation was found to be ineffective.

Precaution when Using Throat Packs

Dr. H. PARRY-PRICE writes: Deaths have been recorded due to the removal of tracheal tubes after tonsillectomy and failure at the same time to remove the throat pack. I have recently instituted what I hope may prove a more or less fool-proof routine to avoid such accidents. All throat packs are soaked in vaseline and kept in a separate tin on the anaesthetic trolley. Thus no packs can possibly be involved in the sister's swab count at the end of the operation. The lid of the throat pack tin is painted red, and across it in white letters THROAT PACK TIN. Directly the tin is opened the lid is hung up on the trolley in a prominent position so that all may see it. It is not replaced until the pack is removed from the throat.

Princess Tsahai Hospital Appointments

MISS E. SYLVIA PANKHURST writes from 3, Charteris Road, Woodford, Essex: Some time ago you were good enough to publish a request that members of the medical profession who might be willing to take up appointments in the Princess Tsahai Memorial Hospital would communicate with the honorary secretary of the Hospital Council. The Council, however, was not able to proceed with the making of appointments, as had been anticipated, at the time, because, on further consideration, it was decided to revise and enlarge the original scheme, and this delayed the whole project. The generous assistance of the eminent hospital architect, Mr. Lionel Pearson, F.R.I.B.A., was obtained in revising the scheme.

Mr. Pearson drew a new set of plans, modifying and enlarging the original partly completed structure, which has been presented to the Council by H.I.M. the Emperor of Ethiopia, and adding new blocks for a big out-patient department and an ample operation theatre, kitchen, etc. The building is now in progress on the revised plans under a contract to be completed on Aug. 25 next. It is hoped that the interior equipment, which is being purchased in this country, may be fitted during the autumn. The Council, therefore, desires to make arrangements well in advance for the staff, and invites applications for the resident posts of physician, surgeon, obstetrician, radiologist, anaesthetist, and other specialists.

The Tuberculous Patient

"A. E." writes: As a doctor's wife now undergoing treatment for tuberculosis, I ask leave to make a few general observations in your columns. I often wonder if the attitude to tuberculosis which I have encountered is the usual one. A fairly common statement (by medical and nursing personnel) is that complaints about the food by sanatorium patients are a symptom of the disease. I am aware that fussiness about food is apt to develop in anyone who is confined to bed, and that in the tuberculous patient this tendency is aggravated by (a) the duration of the illness, and (b) the patient's awareness that an exceptionally nourishing diet is an essential part of his treatment. I would suggest that the sanatorium physician who neglects to investigate thoroughly all complaints about the food may be saddling his patient with the extra burden of frustration. Perhaps the most saddening aspect of the thing is that the vast majority of patients dare not press their complaints, being completely in the hands of the authorities, and knowing that in the event of their being expelled from their city, or county, sanatorium while still "open" case they run the risk of infecting their relatives. One would imagine that the physician, aware of his omnipotence in this matter, and being possessed of a conscience, would be specially punctilious in the appreciation of his exceptional power. I must also add that it sometimes seems to me that while we still await the State Medical Service itself, some of its alleged "attendant evils" are with us already and have been with us for many a long day. Tuberculosis, after all, is not a "rare" disease in this country, but it is fairly obvious that its victims are denied freedom of speech in many quarters—I speak from personal experience, and from the hearsay evidence of many responsible people.

Perhaps the present era of shortage of nursing and domestic staff is not the moment to broach this other point—but it is at least worth bearing in mind for the future. I refer to the unwillingness of nurses to give more than the bare minimum of attention to their patients. Many of these girls are untrained, certainly, but I fear there is often official backing for their ungraciousness. Instances of apparently meaningless, and certainly exasperating, petty restrictions could be cited. Perhaps I have been unfortunate in my past experiences, and I am glad to put on record that in my present place of treatment I have been given every consideration, and have found conditions—especially in view of the food shortage and other handicaps—wellnigh perfect.

The chances of survival of the tuberculous patient (thanks to the improved methods of local treatment, and their efficient application) are growing daily greater. I make the plea that he be not returned to the outside world healed in body but embittered in spirit, and that his recovery be not retarded by an unsympathetic environment. Although my own illness has now lasted for eighteen months, I have never been acutely ill, and have good grounds for believing that within eight to ten months I may once more be able to lead a normal life. Therefore I speak in a spirit of constructive criticism, rather than one of bitterness and frustration.

DISTRIBUTION OF PENICILLIN

On June 1 the present free issue of penicillin by the Ministry of Supply through the hospital system will cease. From that date penicillin will be available to hospitals, to the medical and dental professions, and to retail pharmacists through trade channels. Supplies should be obtained from the usual suppliers of such products. Penicillin or any preparation containing it may be supplied to the public only against the prescription of a registered medical or dental practitioner.

Initially most of the penicillin will be in the form of dried powder packed in phials or ampoules containing 0.1, 0.2, 0.5, 1.0 mega unit. The maximum retail prices of these packs will be 2s. 9d., 4s. 9d., 10s. 6d., and 20s. respectively. Penicillin will also be available in an oil-wax suspension for injection. Pharmacists may use dried penicillin in dispensing the prescriptions of medical and dental practitioners. As time goes on increasing quantities of penicillin preparations will become available from the manufacturers.

Should any difficulty be experienced in obtaining supplies, advice may be sought from the Ministry of Supply, Penicillin Production Control, Tothill Street, London, S.W.1. (Telephone No. 7788, Ext. 403.)

PROGRESS AFTER PERFORATED PEPTIC ULCER*

BY

C. F. W. ILLINGWORTH, M.D., Ch.M., F.R.C.S.Ed. L. D. W. SCOTT, M.D., M.R.C.P.

AND

R. A. JAMIESON, F.R.C.S.Ed.

It is a common experience that acute perforation of a peptic ulcer may lead to a remission of symptoms, but there is little evidence as to the expectation of such improvement or the risk of relapse, and still less about the factors influencing the prognosis. Accordingly it seemed useful, as part of a broad survey of perforated ulcer, to carry out a careful follow-up study of a large series of cases.

Particulars of Survey

Method of Study.—The survey is based on all patients treated for acute perforation at the Western Infirmary of Glasgow during the period 1938–43. There were 880 such patients, of whom the 733 survivors (83%) form the material surveyed. An attempt has been made to trace all these survivors and recall them for examination. A large proportion of the patients were traced by letter and readily agreed to report. When this failed, the almoner visited the patient in his home and urged him to attend. For patients living at a distance the help of Red Cross workers and other voluntary organizations was elicited. Where the patient had left his former address and could not be traced by post, his present address was sought from the family doctor, from relatives, or from neighbours. By these various methods we were able to trace 666 of the 733 survivors, and, of these, 596 attended for follow-up examination.

Total number of patients treated for perforation	880
Survivors	733
Traced by letter	596
Traced by other methods	43
Completely untraced	17
	66
	67

The Population subjected to Survey.—Nearly all the patients followed up came from Glasgow and the adjacent districts; 95% were men, and the ulcer was situated in the duodenum in 87% of cases. The age distribution was as follows:

Age (at Perforation) of Survivors Interviewed

Age (Years).	15-20	25-30	35-40	45-50	55-60	65-70	75-79	All Ages						
Cases ..	33	49	51	74	89	86	64	63	37	29	15	4	2	596

Operation and Post-operative Care.—In all but 10 cases the operative treatment was limited to closure of the perforation; in the remainder a simultaneous gastro-jejunostomy was performed. Most patients were discharged after a stay in hospital of 14 to 21 days. A few received further care in a convalescent institution, but the majority were discharged to their homes. They returned to work usually in 3 to 4 months. All patients on discharge from hospital were given instructions as to diet and medication. Inquiry during the follow-up examination made it clear that most of them attempted to follow the

instructions for some months, but few persisted for more than a year. At the time of the examination the majority were taking advantage of the special milk and egg ration, but admitted that their only dietary restriction was to avoid the foods which, from experience, were known to cause indigestion; while as to medication, few did more than take an alkaline powder when symptoms were present. This state of affairs, lamentable though it is as a reflection on the impracticability of medical measures in a working-class population at the present time, has the advantage of providing for our survey a series of peptic ulcer cases whose post-operative course has been practically uninfluenced by treatment.

Method of Tabulation.—The investigation was carried out in 1944 and the early part of 1945. Consequently at the time of examination five years or more had elapsed in some cases since perforation, while in others the period was shorter. For the purpose of analysis we have tabulated the follow-up state for each period of 12 months post-operatively and treated the series as a whole. It follows that, while we have records of the whole series for the first year after perforation, the number of cases followed up for longer periods is smaller, and a full five-years follow up is available only for those who perforated in 1938–9.

Assessment of Clinical State.—At the follow-up examination patients who had suffered a relapse were graded according to the severity and persistence of the symptoms. An attempt to base a grading on loss of working time was soon abandoned, since it was found that many patients remained at work even though suffering severe indigestion. For the purpose of this paper we have adopted a simple clinical grading into three groups (1) those completely free from symptoms; (2) those who have suffered mild indigestion; and (3) those who have had attacks of severe indigestion, together with those who have suffered haemorrhage or re-perforation or undergone elective operation.

Record of Progress after Perforation

One method of presenting the progress after perforation is to record the number (or proportion) of patients who have remained continuously symptom-free and those who have suffered a mild or severe relapse. The findings in our series of cases analysed in this way are presented in Fig. 1 and Table I. It will be noted that at the end of the first year rather more than 60% of patients have remained free from symptoms, while about 20% have had a relapse with mild symptoms and the remaining 20% have had a severe relapse. The percentage who have sustained a relapse increases with the passage of time. By the end of the fifth year about 30% have remained continuously symptom-free, 20% have had a mild relapse, and as many as 50% have had a severe relapse.

Year-by-Year State of Health.—The method used above may be criticized as painting too gloomy a picture of the progress, for peptic ulcer is notoriously liable to remissions, and a patient who in one year sustains a relapse may subsequently enjoy a long spell of good health. This difficulty we have met by presenting a "year-by-year" statement in which is recorded

* This paper is based on observations made in the course of a survey of peptic ulcer carried out under the auspices of a Committee on Sickness Records set up in Glasgow by the Nuffield Provincial Hospitals Trust.

FIG. 1.—Progress after perforation. Showing (a) proportion of patients continuously symptom-free; (b) proportion of patients who have had mild indigestion. (See Table I.)

TABLE I.—Progress after Perforation

Year of Follow-up:	1st	2nd	3rd	4th	5th
No symptoms ..	392	254	160	107	47
Mild symptoms ..	110	147	140	97	41
Severe symptoms ..	94	151	157	136	78
Total cases ..	596	552	457	340	166

for each of the post-operative years the number (or proportion) of patients who *during that year* have remained symptom-free or have suffered mild or severe relapses. Our results are analysed in this way in Fig. 2 and Table II, and it will be seen by

FIG. 2.—Year-by-year state after perforation. Showing (a) proportion of patients symptom-free in current year; (b) proportion of patients with mild indigestion in current year. (See Table II.)

TABLE II.—Year-by-year State after Perforation

Year of Follow-up.	1st	2nd	3rd	4th	5th
No symptoms ..	392	277	191	144	76
Mild symptoms ..	110	149	150	107	45
Severe symptoms ..	94	126	116	89	45
Total cases ..	596	552	457	340	166

comparison with Fig. 1 and Table I that the effect of allowing for prolonged remissions becomes obvious in the later years of the follow-up. Thus the proportion of patients who are symptom-free falls from about 60% for the first year to 50% for the second year, but thereafter remains above 40%, while the proportion of patients with no more than mild indigestion remains above 70%. The proportion with severe relapses varies between 20 and 30%.

This estimate of the yearly state of health of our ulcer population may be of value from the economic standpoint. We have shown that the proportion of patients having no more than slight indigestion tends to stabilize between 70 and 80%. It would seem reasonable to suppose that, of a group of workers who had survived perforation, approximately the same proportion should be healthy enough to remain in continuous employment during any one year.

Incidence of Major Complications.—In Table III we give the number of patients who suffered re-perforation or haemorrhage, together with those who subsequently underwent an elective operation for the relief of ulcer symptoms. It will be noted

TABLE III.—Major Complications after Perforation

Year of Follow-up:	1st	2nd	3rd	4th	5th
Cases observed ..	596	552	457	340	166
Re-perforation ..	10 (1.7%)	8 (1.4%)	11 (2.4%)	5 (1.5%)	4 (2.4%)
Haemorrhage ..	5 (0.8%)	7 (1.3%)	7 (1.5%)	4 (1.2%)	1 (0.6%)
Elective operation ..	16 (2.7%)	12 (2.2%)	8 (1.8%)	3 (0.9%)	3 (1.8%)

that in each of the post-perforation years roughly 2% of patients suffered re-perforation, roughly 1% sustained a haemorrhage, and roughly 2% found it necessary to undergo operation for the relief of symptoms. It will be observed also that the incidence of major complications showed little sign of diminishing with the passage of time: it was almost as high in the fifth post-operative year as in the first. Even allowing for the few who appear more than once, we estimate that within five years of perforation some 20% of patients may be expected to suffer a major complication.

Mortality after Perforation.—Of the 666 traced survivors from the original operation 43 are known to have died during the period of the follow-up survey. In 11 cases death resulted from a complication of peptic ulcer (re-perforation 7, haemorrhage 0, elective operation 4). In 23 cases death was attributable to causes other than peptic ulcer. In the remaining 9 cases the cause of death was not known.†

Factors Influencing Progress after Perforation

In our survey we have studied the possible influence of various factors on the progress after perforation. In this paper we present our results in relation to the sex and age of the patient, the duration of symptoms, and the social status. The influence of other factors will be discussed in subsequent papers. In presenting our results we have used as the index of progress the proportion of patients continuously symptom-free, but we have verified that what is said is also applicable to the year-by-year state of health.

Influence of Sex.—Of our 596 cases only 28 were women. They appeared to fare somewhat better than the men, but the number of women is too small to allow a reliable comparison to be made.

Influence of Age.—To assess the influence of age on progress we have divided our series of cases into three groups, of approximately equal size, according to age at the time of perforation—those aged 34 years or less, those aged 35 to 49 years, and those aged 50 or more. The progress of these groups is recorded in Fig. 3 and Table IV. It will be seen that the oldest group fared better than the younger groups. For example, in the oldest group the proportion symptom-free after

† The mortality among survivors from perforation has been investigated from the actuarial standpoint by Mr. W. Lundie, F.F.A., who has compared the actual deaths in our series with those which might be expected on the basis of a mortality rate calculated for Glasgow at the present time. While the number of deaths in our series is too small for reliable conclusions, it is probable that the mortality among our survivors from perforation is in excess of expectation. The excess might be wholly accounted for by the deaths due to further complications of ulcer.

FIG. 3.—Influence of age (at perforation) on subsequent progress. Showing proportion of patients continuously symptom-free. (See Table IV)

TABLE IV.—Influence of Age (at Perforation) on Subsequent Progress

Year of Follow-up.		1st	2nd	3rd	4th	5th
Age 15-34 years	Symptom-free	135	81	48	37	19
	Total cases	207	193	165	130	73
Age 35-49 years	Symptom-free	155	99	55	35	17
	Total cases	239	222	178	126	58
Age 50-76 years	Symptom-free	102	74	57	35	11
	Total cases	150	137	114	84	35

For 3rd follow-up year $\chi^2 = 14.82$, P less than 0.01 For other follow-up years P exceeds 0.05.

three years was 50%, as against 30% in the younger groups. Using as our index the proportion of patients continuously symptom-free, the outcome in the middle and young age groups was almost identical, as is seen in Fig. 3 and Table IV. Examination of our records shows, however, that had we used as our index the proportion free from severe symptoms (i.e. those symptom-free and those with mild indigestion taken together) the age groups would appear in orderly sequence, with the oldest group progressing most favourably and the youngest least favourably. We concluded that among patients who survived perforation the prognosis is best in the old and worst in the young.

Influence of Duration of Symptoms—Fig. 4 and Table V show the progress of groups of patients classified according to the duration of symptoms prior to perforation. It will be noted that the outcome is more favourable in the groups with a short antecedent history of dyspepsia than in the groups with a long history. Not only are the differences material, but the groups follow each other in orderly sequence. Thus patients with no previous history of dyspepsia fared better than patients who had symptoms for 0 to 3 months, who in turn fared better than patients who had symptoms for 3 to 12 months, and so on.

Influence of Social Status—We have also studied the effect of social status on the progress after perforation, and in view of the present interest in the social aspects of medicine we believe that our findings are worth recording. For this purpose we have used the scheme of social grading adopted by the Registrar-General for England and Wales. In this scheme Grade I includes members of the professions, Grade III includes skilled artisans, and Grade V includes unskilled workers; while Grades II and IV are intermediate. With our patients grouped according to this classification we have compared the post-operative progress, using as our index in turn the proportion continuously symptom-free, the proportion continuously free from severe symptoms, and the corresponding figures relating to the year-by-year state. In none of these comparisons have we been able to demonstrate a difference in the outcome of the various social grades, whose progress, with

FIG. 4.—Influence of duration of symptoms before perforation on subsequent progress. Showing proportion of patients continuously symptom-free at follow-up: a = No symptoms before perforation; b = Symptoms for 0-3 months before perforation; c = Symptoms for 3-12 months before perforation; d = Symptoms for 1-5 years before perforation; e = Symptoms for more than 5 years before perforation. (See Table V)

TABLE V.—Influence of Duration of Symptoms Before Perforation on Subsequent Progress

Year of Follow-up		1st	2nd	3rd	4th	5th
None	Symptom-free	43	39	20	16	2
	Total cases	54	53	37	35	13
0-3 months	Symptom-free	49	36	19	15	6
	Total cases	62	56	41	32	17
3-12 months	Symptom-free	43	31	16	11	6
	Total cases	56	54	38	32	17
1-5 years	Symptom-free	77	49	29	22	8
	Total cases	119	111	84	71	37
More than 5 years	Symptom-free	159	93	58	38	21
	Total cases	263	250	190	155	76

χ^2 test applied to each follow-up year = for 1st and for 2nd year, P less than 0.01; for 3rd and 4th years, P less than 0.05

one exception, has been uniform. The exception was the class of semi-skilled workers (Grade IV), whose progress after perforation was notably favourable. For this anomaly there is an unexpected explanation—namely, that our Grade IV patients happened by chance to include an excessive number who gave a short history of dyspepsia before perforation, and who, as we have stated, must be expected to show a favourable outcome. There is therefore no evidence that the progress after perforation in this series was modified by the social status of the patient.

Discussion

Many follow-up studies of peptic ulceration have been published, but comparison of their results is difficult owing to the lack of a standard pattern of presentation. The series may include cases of different types treated by a variety of medical or surgical methods. The duration of the follow-up period may be inconstant, and one sometimes sees such statements as "in cases followed from two to ten years the proportion of cures was so-and-so." Lastly, the grading of cases according to the severity of symptoms, particularly under such categories as "I.S.Q." or "Improved," gives infinite opportunities for individual variation.

In this series we have the primary advantage of dealing with a group of patients who are uniform in two respects—namely, that all have peptic ulcers which have perforated, and that their post-operative course has been practically uninfluenced by treatment. In our clinical assessment we have adopted grading which is as free as possible from the errors of individual variation. We have recognized three grades—namely, "symptom-free," "mild indigestion," and "severe relapse." In our study of the factors influencing progress we have used as our index the simple criterion "continuously free from all digestive

symptoms." The use of this high standard of health has been necessary in the present series, because a considerable number of our patients suffered perforation (or re-perforation) after having had only slight occasional indigestion.

In the presentation of our results we have followed the method by which the series is treated as a whole, and the follow-up records are tabulated for each period of 12 months. In reporting the progress of a disease such as peptic ulcer, which is prone to remissions and recurrences, this seems to us to be the best method of giving an accurate picture.

Although, as we have said, the published studies of peptic ulceration follow no standard pattern, one finding is common to all—namely, the longer the follow-up period the greater the number of relapses—and the impression grows that what is being shown is not so much the result of treatment as the natural history of the disorder.

Some observers believe that the prognosis as regards future health is better in cases of perforation than in any other form of peptic ulcer. This opinion can be supported by considerations of pathology. It is the ulcer on the anterior wall of the duodenum which commonly perforates, and consequently these ulcers can penetrate only to a shallow depth before being treated surgically. On the other hand, ulcers on the posterior duodenal wall can penetrate deeply into the substance of the pancreas, creating conditions which make healing difficult, if not impossible. However, our findings provide little support for the view that the peptic ulcer which perforates runs a satisfactory course. It is possible that the non-perforating ulcer has an even worse record as regards health, but until we have completed the study of a group of non-perforating ulcers we are not prepared to say much about this, apart from observing that, since in the present series of patients the incidence rate of major complications within five years of perforation was 20%, the standard of health set by the perforating ulcer is not high.

It is noteworthy that in the great majority of cases acute perforation of an ulcer is followed by a remission of symptoms for, at any rate, a period of months. It is commonly averred that "perforation cures an ulcer"—by which it is implied that healing is due to the actual rupture, associated as it is with sloughing and removal of the fibrous bed of the crater. It seems more probable that the remission of symptoms is due to the rest in bed, the careful diet, the prolonged convalescence, and perhaps the alteration of mental outlook induced as a result of the operation.

The influence of the duration of ulceration before perforation (as judged by the history) on subsequent health is interesting. The longer the ulcer has been present before perforation the poorer the health in the post-operative years. In all probability this is accounted for by the structural changes accompanying chronic ulceration, but proof of this would depend on obtaining an adequate view of the ulcer at the time of operation, and for technical reasons this is not possible.

It is more difficult to suggest a reason why those who perforate in later life should have a better record of health after recovery from the operation than the younger men. The difference is not due to an excessive proportion of chronic ulcers in the younger age groups. It is possible that the difference may be related to factors connected with occupation, psychology, or dietary habits, or to a greater readiness on the part of older patients to submit to a more ordered regimen of life. The question certainly deserves further study.

It is a common belief that the treatment of peptic ulcer gives more satisfactory results in private than in hospital practice, and this is thought to be related to economic factors. The Registrar-General's classification of the population into five social grades corresponds roughly to income levels and provides a way of studying the influence of economic factors on disease. As has been shown, we have been unable to detect any difference in the morbidity between the various social grades in our series. This finding is surprising, and clearly merits further study. However, it should be noted that the period of follow-up coincides largely with the rationing of foodstuffs, and there can be no doubt that dietary differences between the various income groups have been greatly lessened during wartime. Furthermore, as we have noted, most patients were taking advantage of the extra allowance of milk and eggs granted in

cases of peptic ulcer, and this should mean considerable uniformity in diet in the different social grades. The increased earnings of the lower social grades in wartime may also have played a part in improving their conditions—although the greater number of hours worked is to be set against this. We have already suggested that working overtime may have been partly responsible for the great increase in the number of cases of perforated peptic ulcer occurring in the West of Scotland in 1941 (Illingworth *et al.*, 1944).

Summary

A follow-up study of 733 patients who had survived perforation of a peptic ulcer is reported, and the following findings are discussed:

(1) Remission of ulcer symptoms after perforation was seldom of long duration. Within one year 40% of patients had relapsed (symptoms were mild in 20% and severe in 20%). After five years 70% had relapsed (symptoms were mild in 20% and severe in 50%).

(2) The incidence rate of major complications (re-perforation, haemorrhage, symptoms requiring elective operation) was 20% within five years of perforation.

(3) The mortality rate among survivors from perforation was somewhat higher than the standard mortality rate. The excess might be accounted for by deaths due to complications of ulcer.

(4) Progress among survivors was best in the old and worst in the young.

(5) Progress was best in patients with a short history of dyspepsia before perforation, and the longer the antecedent history the worse was the progress.

(6) Progress was not modified by the patients' social status.

We are indebted to our surgical colleagues at the Western Infirmary, who have given us full access to their case records and every facility for following up their patients. It is literally true that without their helpful co-operation this paper could not have been written. We have pleasure in acknowledging our debt to Mr. W. Lundie, C.A., F.F.A., who at the suggestion of Mr. J. G. Kyd, Registrar-General for Scotland, has submitted our mortality rate to an examination from the actuarial standpoint. Our thanks are due also to Miss Wood, our social worker, for her help in tracing many patients and securing their attendance for the follow-up; and to Miss Good for her tireless attention to the secretarial work involved in the collection of records.

ONE HUNDRED CASES OF PERFORATED PEPTIC ULCER

WITH AN ANALYSIS OF IMMEDIATE AND REMOTE RESULTS OF SIMPLE CLOSURE

BY

FRANK FORTY, M.B., B.S., F.R.C.S.
Surgeon, Redhill County Hospital, Redgware

Perforated peptic ulcer is a subject with a vast and steadily growing literature. Formerly this was concerned mainly with problems of diagnosis, choice of operation, and immediate post-operative results.

Compared with most abdominal emergencies, the diagnosis of perforated gastric and duodenal ulcers now presents few difficulties. Their treatment likewise admits of no division of opinion so far as the need for closure of the perforation at the earliest possible moment is concerned. Fashions in abdominal surgery have, however, been reflected in the periodical shift of opinion as to what other operative procedures might with advantage be used as a supplement to simple closure of the perforation. Whilst one school of thought has persistently held that so grave an emergency called for the performance of the simplest life-saving operation, others have seen fit to employ gastro-enterostomy and, more recently, partial gastrectomy in the initial treatment of perforations. Less popular devices such as local excision of the ulcer and pyloroplasty have similarly had their advocates as and when each became current in the treatment of non-perforated ulcers.

It may be suspected that the advocacy of these various measures has not been wholly free from a tendency to rationalization. Thus, for instance, the enthusiasts for gastro-enterostomy convinced themselves that the suture of an ulcer

in the vicinity of the pylorus involved a high incidence of pyloric stenosis and obstruction, which justified the performance of a gastro-enterostomy for its prevention as part of the initial operation for a perforation. Similarly, the more recent adoption of partial gastrectomy as the operation of choice in the treatment of gastric and duodenal ulcers has been followed by a wave of popularity for the view that ulcers which have previously perforated frequently remain active or break down again, and that the immediate performance of a partial gastrectomy is justified as the surest means of protecting the patient from this hazard.

Considering the comparatively small amount of evidence that has hitherto been published concerning the later progress of patients who have survived the perforation of a peptic ulcer, it would seem that these views, no less than the widely held opinion that suture of a perforation commonly leads to the permanent cure of the ulcer, are largely based on vague impressions rather than upon factual knowledge derived from the prolonged and close observation of the results of simple closure. Patients discharged from hospital after suture of a perforation have not, on the whole, been followed up with the same care and persistence as have those who have received medical or surgical treatment for unperforated ulcers.

Latterly, publications on this subject have increasingly recorded the results of following up the cases over considerable periods. The present investigation is reported as a contribution to the more exact knowledge of long-term prognosis which is being gained as a result of such inquiries.

Material and Method of Investigation.—The material of this paper consists of 100 consecutive cases of perforated gastric and duodenal ulcers on which I operated at Redhill County Hospital, Edgware, during the five years 1938–43; 88 occurred in men and 12 in women. The patients who survived were re-examined at intervals of six weeks, three months, and six months after discharge from hospital, and thereafter every six months. Clinical examination was supplemented by x-ray investigation approximately once a year, whether there was a recurrence of symptoms or not, and more often when there were special indications.

Operative Procedure and Immediate Post-operative Results

Operation was undertaken at the earliest possible moment after admission to hospital. Glucose-saline was administered by rectal drip as a routine for the first 24 hours after operation. Fluids were then allowed by mouth and the diet was gradually increased.

Anaesthesia.—A general anaesthetic was administered in the majority of cases, using gas-oxygen and ether.

Incision.—The usual method employed was to open the abdomen through a right paramedian incision, either splitting the rectus muscle or displacing it laterally. Displacement of the rectus gave appreciably stronger scars than did splitting the muscle, and the latter has now practically been abandoned. There was no greater tendency to wound sepsis after displacement of the rectus muscle, and the time that can be saved by splitting it is quite negligible.

Intra-abdominal Procedure.—In all cases but one, simple closure of the perforation, with or without drainage of the peritoneal cavity, was carried out. A single chromic catgut suture was passed through all layers to approximate the edges of the perforation. Occasionally, when the perforation was very large or the tissues were unusually friable, a second such suture was introduced at right angles to the first. The ulcer was then invaginated by a row of three interrupted Lembert stitches passed in the long axis of the stomach and duodenum, the ends being left long to tie over and secure any available piece of omentum as a patch. A toilet of the peritoneal cavity was next carried out, excess of fluid being removed by means of moistened gauze mops. A sufficiently large abdominal incision was made to allow of a hand being freely introduced for this purpose, and the areas receiving routine attention were: (1) the space between the right lobe of the liver and the diaphragm, whence a considerable quantity of locked-up fluid can generally be released; (2) Morison's pouch between the under surface of the liver and the hepatic flexure of the colon; (3) the pelvis and the right paracolic gutter; (4) the space between the splenic flexure and the diaphragm, where fluid

particularly collects in perforations of a gastric ulcer. I have repeatedly noted the localization of the bulk of the fluid to one or other of these compartments, and I believe that a systematic toilet of the abdomen in this manner is of considerable importance in minimizing the incidence of post-operative peritonitis and of subphrenic and pelvic abscesses. The use of a sucker introduced through a small abdominal incision is not an adequate substitute for gauze swabs carried by a hand to each of the areas mentioned above.

Drainage of the peritoneal cavity was carried out in 54 cases. In 47 of these the drain was introduced to the bottom of the pelvis, a suprapubic "stab" wound being employed in 41 cases; in the remaining 6 cases a right gridiron incision which had been made for exploration in suspected appendicitis was used. In 7 cases with long-standing perforation and a perigastric abscess a local drain to the site of the ulcer was brought through the paramedian incision. The remaining 46 cases were closed without any drainage.

Post-operative Complications

Some infection of the wound occurred in 14 cases, of which 10 had been drained suprapubically and 4 had been closed without drainage. Two of these patients died—one on the 20th post-operative day with an empyema, and the other from spreading gangrene of the skin 5 months after operation. Pulmonary complications occurred in 39 cases, but were mild and recovered quickly in all but 7 cases of severe bronchopneumonia, which accounted for 5 deaths. Two empyemas occurred, with one death. Two subphrenic abscesses formed, with one death. Seven patients complained of digestive symptoms while still in hospital and one had a haematemesis. In 41 cases post-operative recovery was completely uneventful.

Deaths

Seventeen deaths occurred in the series. These are analysed in Tables I and II.

TABLE I.—Causes of Death

Cause of Death	Broncho-pneumonia	Tetanus and Shock	Cardiac Failure	Wound Sepsis	Sub-phrenic Abscess	Empyema	Total
No. of cases	5	6	3	1	1	1	17

TABLE II.—Cases and Deaths in Each Decade of Life

Decade	1st	2nd	3rd	4th	5th	6th	7th	8th
Total No. of cases	0	3	12	23	27	9	18	3
No. of deaths	0	0	0	1	6	1	6	3

Table II shows the relative total number of cases and of deaths in each decade of life. Under the age of 40 there were 43 cases, with one death; over the age of 40 there were 57 cases, with 16 deaths. There were 12 deaths among the men and 5 among the women. Thus whilst the cases occurring in women were 12% of the total, 29% of the deaths were among the women.

Anatomical Site of Perforation

The term "juxtapiyoric" has been used to describe those of the ulcers which were in very close relation to the pylorus and about whose classification as either gastric or duodenal differences of interpretation might arise. In my opinion the majority of these were on the duodenal side of the pylorus. This view is supported by the post-operative x-ray appearances. Deformities due to scarring or to persistent ulcers, when present, were almost always found to be in the duodenum. Adopting this terminology, the distribution of the perforations was as follows: gastric, 12; juxtapiyoric, 58; duodenal, 30. Five of the 17 deaths in the whole series occurred amongst the gastric ulcers. Five of the 12 gastric perforations occurred in women, with 3 deaths.

From these figures it appears that much the highest mortality was associated with the gastric perforations—42%, as compared with 15.5% for the juxtapiyoric and 10% for the duodenal cases. Furthermore, the higher incidence of gastric perforations among women largely explains why there were proportionately so many more deaths in women than in men.

Attendance at Follow-up Clinic

Of the 83 patients who left hospital alive after operation, 13 were lost sight of immediately and 70 attended in the follow-up clinic for varying periods. Table III shows an analysis of these attendances.

TABLE III

Duration of Attendance:	1 Year or Less	Up to 2 Years	Up to 3 Years	Up to 4 Years	5 Years and Over	Total
No. of cases	25	16	6	13	10	70

That only 10 of the 70 patients should have continued to attend for as long as five years might be considered to be somewhat disappointing. It should be noted, however, that the period covered by this investigation coincided with the war years, when evacuation, call-up to the Forces, and transfers of industrial labour took an exceptionally heavy toll of attendances. This disadvantage is to some extent offset by the fact that the observation of these patients with peptic ulcer histories was carried out at a time when dietetic, living, and working conditions were particularly adverse for people suffering from digestive disorders.

Recurrence of Symptoms

During the time of their attendance in the follow-up clinic 38 patients had a recurrence of digestive symptoms. These were classified as "slight" (13 cases), with a complaint of occasional discomfort after eating, heartburn, or flatulence; "moderate" (11 cases), whose indigestion involved periods of absence from work but which responded to domiciliary treatment; and "severe" (14 cases), which required readmission to hospital for medical treatment or for the performance of a secondary operation.

The time which elapsed between operation and the first onset of a recurrence of digestive symptoms is shown in Table IV.

TABLE IV

Year after Operation.	1st	2nd	3rd	4th	5th
No. of recurrences	25	3	3	5	2

In Table V the number of recurrences of symptoms is related to the age groups in which they occurred.

TABLE V

Decade of Life:	2nd	3rd	4th	5th	6th	7th
Total No. of perforations	3	12	28	27	9	18
Total No. of recurrences of symptoms	1	6	10	9	3	3
of severe and moderate	1	1	7	6	2	3

Table VI shows the relation of the duration of ulcer symptoms before perforation to the rate of incidence of post-operative recurrence of indigestion.

TABLE VI

Length of Past History:	3 Years or Less	3 to 5 Years	5 to 10 Years	10 to 20 Years
No. of cases	47	12	19	10
No. of post-op recurrences	8	3	6	4
Recurrence rate	17%	25%	32%	40%

The following inferences may be drawn from the evidence summarized in Tables IV, V, and VI.

1. A high rate of recurrence during the first year after perforation is followed by a sharp drop during the second year, a fairly constant low level of recurrence being then maintained during succeeding years (Table IV). The numerous recurrences during the first year are probably evidence that suture of the perforation failed to heal the original ulcer in those cases, whilst the recurrences of symptoms during the second and later years were almost certainly due to re-ulceration of a previously healed ulcer or to the formation of completely new ulcers. A striking example of this was a man who had a perforation of a duodenal ulcer and then remained completely free from digestive symptoms for four years. During the fifth year after perforation he developed symptoms of a gastric ulcer, with

pain immediately after food. Skiagrams showed a large crater at the middle of the lesser curvature. A partial gastrectomy was performed, and the ulcer was found to be perforating into the pancreas.

2. The rate of recurrence of ulcer symptoms for each decade of life runs roughly parallel with the total incidence of perforations in the series for the corresponding age groups, each being maximal during the fourth and fifth decades.

3. The longer the patient has suffered from an ulcer before he perforates the more likely will he be to have a recurrence afterwards.

In general, it may be surmised that suturing the perforation in itself has little influence on the natural history of the ulcer, and that the immunity from further symptoms enjoyed by 32 of the patients among those observed in the present series was mainly due to the three weeks of complete rest and strict dietetic regime enforced during convalescence in hospital, combined with their ready observance of the instructions which they received on discharge, lest the price of carelessness should be a repetition of their recent ordeal. Those who have had a perforation have been warned, and they are not likely to forget. But the long-standing chronic ulcer is no more susceptible of cure by purely medical means after perforation than it was before, and it is in this group of cases that radical surgery after perforation finds its chief justification.

X-Ray Examination

At the follow-up clinic 130 x-ray examinations of the stomach and duodenum were made on the 70 patients who attended—54 during the first year after perforation, 32 during the second year, 18 during the third year, 16 during the fourth year, 9 during the fifth year, and 1 during the sixth year. The significant results of these examinations are given in Table VII.

TABLE VII

Year After Perf.	Normal	Irritability and Hypersecretion	Pyloric Spasm	Duodenal Ulcer	Gastric Ulcer	Pyloric Obstruction	Doubtful
1st	14	7	6	13	2	2	1
2nd	7	4	2	8	2	1	3
3rd	5	2	0	6	0	0	2
4th	4	1	0	4	1	1	1
5th	0	0	0	5	1	1	1
6th	0	0	0	1	0	0	0
Total	30	14	8	37	6	5	8

The striking feature of these records is that in the course of 130 x-ray examinations pyloric obstruction was encountered only five times, whilst the appearances of an active ulcer crater were present on no fewer than 43 occasions. The performance of a gastro-enterostomy as part of the initial operation for a perforated peptic ulcer is therefore quite unjustified in view of the very low incidence of pyloric obstruction as a remote complication after simple suture of the perforation.

The 43 occasions on which the niche or crater of an ulcer was seen occurred in the course of the x-ray examination of 31 different patients. Of these, 24 suffered from recurrent symptoms of indigestion. In the case of the remaining 7 patients the x-ray appearances were probably due to the effects of the scarring of healed ulcers.

Secondary Operations

Secondary operations were performed on 10 patients. One of these was an emergency operation necessitated by a second perforation of a duodenal ulcer after an interval of 4 years and 3 months. During this interval the patient, a man aged 66 at the time of his first perforation, had remained completely free from symptoms until a fortnight before the second perforation, when he had a recurrence of indigestion. Skiagrams then showed slight deformity of the duodenal cap, thought to be due to scarring of the old ulcer. At the second operation a large juxta-pyloric perforation was found. When last seen, 18 months after the second operation, he had again remained free from symptoms, and was in good health at the age of 72. A further skiagram at this time showed deformity of the first part of the duodenum. The stomach emptied rapidly and there was no pyloric stenosis.

The remaining 9 secondary operations were performed because of symptoms which persisted in spite of medical treatment or on patients whose livelihood depended upon an

occupation incompatible with adherence to a gastric regime adequate to keep them free from symptoms. The latter circumstance occurs commonly among hospital patients in an industrial district, and is a factor which, when duly taken into account, must be regarded as a strong indication for advising partial gastrectomy more frequently than would be justifiable in more sheltered sections of the community. The secondary operations performed are analysed in Table VIII.

TABLE VIII

Case No.	Condition	Secondary Operative Procedure	Interval After Perforation	Result
6	Pyloric obstruction	Gastro-enterostomy	6 months	Remained symptomless
9	Duodenal ulcer	Partial gastrectomy	4 years	Died
26	D.U. and pyloric obstruction	Gastro-enterostomy	4 years	"
31	Pyloric obstruction	"	1 year	Remained symptomless
42	Gastric ulcer	Partial gastrectomy	5 years	"
44	Duodenal ulcer	"	1 year 3 months	"
45	Hour-glass stomach	Gastro-gastrostomy	2 years	"
62	D.U. and pyloric obstruction	Gastro-enterostomy	6 months	"
88	Duodenal ulcer	Partial gastrectomy	9 months	"

Two post-operative deaths occurred among the 9 patients who were submitted to an elective secondary operation. One was that of a man of 69 on whom a gastro-enterostomy was performed, and occurred from progressive heart failure five days after operation. The other occurred from acute haemorrhagic cystitis and bronchopneumonia five days after the performance of a partial gastrectomy on a woman aged 44. One woman aged 37 was completely relieved of digestive symptoms by a gastro-enterostomy, but died six months later of a carcinoma of the ovary (Case 6). Of the remainder, two patients who had a gastro-enterostomy performed for pyloric obstruction are alive and well, and have remained entirely free from symptoms four years and nine months and five years after operation respectively (Cases 62 and 33).

Three patients are alive and well seven months, three years, and four and a half years after performance of a partial gastrectomy, and have been completely relieved from digestive symptoms. Two of these operations were necessitated by renewed activity of a duodenal ulcer (Cases 44 and 88), and the third by a lesser-curve ulcer of the stomach which developed five years after perforation of a duodenal ulcer (Case 42).

One patient remains well and has had no recurrence of symptoms three years after a gastro-gastrostomy. This operation was performed for an hour-glass contraction of the stomach opposite a lesser-curve ulcer which had perforated two years previously. The patient was a man, aged 52, who was considered to be unfit to stand a partial gastrectomy. He made an entirely uncomplicated recovery from the gastro-gastrostomy, with immediate relief of the severe pain from which he had suffered for six months. He has now remained free from symptoms for three years and nine months (Case 45).

Summary and Conclusions

A series of 100 cases of perforated peptic ulcer were treated by simple suture of the perforation, with 17 deaths. The death rate was highest among the gastric ulcers, and the incidence of these was higher in women than in men.

The after-history of 70 of the 83 surviving patients was studied in a follow-up clinic for periods up to five years.

A recurrence of digestive symptoms occurred in 38 cases, in 14 of which they were severe enough to require readmission to hospital. The rate of recurrence of symptoms was highest in those patients who had suffered longest from their ulcer before perforation occurred.

On the 70 patients attending the follow-up clinic 130 x-ray examinations of the stomach and duodenum were made. Evidence of a persistent or recurrent ulcer was found on 43 occasions. Pyloric obstruction was found on only 5 occasions.

Ten secondary operations were performed, with 2 deaths: suture of a second perforation (1 case), gastro-gastrostomy for hour-glass stomach (1 case), gastro-enterostomy for pyloric obstruction (4 cases), partial gastrectomy for recurrent ulcers (4 cases). There has been no return of digestive symptoms after any of these operations.

The evidence of this investigation provides no justification for supplementing suture of a perforation by either gastro-enterostomy or partial gastrectomy as an initial procedure. The proportion of cases eventually requiring secondary operations is in the region of 10 to 15%. Periodical re-examination will reveal the need for these when it arises, and the operations can then be performed with good results.

THE PROGNOSIS OF IMMATURITY

BY

CÉCILE ASHER, M.D., B.Sc., M.R.C.P., D.C.H.

Assistant Medical Officer of Health, Finchley; Formerly, Assistant Physician, Duchess of York Babies' Hospital, Manchester

There are two questions to be answered in any case of immaturity: (1) Is the child likely to survive?; and (2) If he survives, will he develop into a normal person or is he likely to be mentally or physically handicapped? In other words, both the immediate and the ultimate prognosis need to be considered. The study reported below deals mainly with ultimate prognosis, but two aspects of immediate prognosis were considered—namely, the effect of birth weight and of sex on survival.

Immediate Prognosis: Method and Scope of Examination

The investigation was carried out at the Duchess of York Babies' Hospital, Manchester, in 1938 and 1939; the case sheets of all children who had been admitted between 1926 and 1938 on account of immaturity, and who had weighed $5\frac{1}{2}$ lb. (2.5 kg.) or less at birth, were examined.

TABLE I—Mortality and Result of Follow-up of Children Admitted to the Duchess of York Babies' Hospital on Account of Prematurity 1926-38

Birth Weight (in lb. (kg.))	Males		Females		Both Sexes	Follow-up			
	No. Admitted	No. Dying	No. Admitted	No. Dying		Cases	Alive	Dead	Untraced
1-2 (0.45-0.9)	4	4	0	6	33	20	2	1*	0
2- (0.9-)	11	10	10	7	30	20	4	2†	0
2½- (1.23-)	19	14	27	34	45	33	20	9	1
3- (1.36-)	25	21	40	37	63	52	37	17	1
3½- (1.6-)	32	31	41	37	73	60	49	11	2
4- (1.8-)	32	10	60	25	92	65	37	5	2
4½- (2.0-)	23	14	50	24	73	62	32	11	0
5-5½ (2.26-2.5)	23	6	74	20	7	65	30	2	0
Total	204	110	193	82		205	53	8	139

* This child was not seen, but was reported as normal by parents.

† These two children were examined. One was seen at the age of 1 year; its mental development was average, but it was under weight. The other child was near the average weight for its age (4 years), but it had Little's disease and a marked degree of mental deficiency (I.Q. 67½).

Chart showing survival rates of immature babies

Proportion surviving the first month: —, Duchess of York Babies' Hospital, Manchester, 1926-38; ---, City of Birmingham Maternity Home, 1931-43.

Proportion surviving the first year: . . . , Duchess of York Babies' Hospital, Manchester, 1926-38; . . . , Warwicks, 1942 and 1943.

Birth weights are given in metric terms in Table I.

The effect of *birth weight* is shown in Table I. This suggests that the child's chances of survival vary directly with the birth weight; the critical birth weight appears to be between 3 and 3½ lb. (1.36 and 1.6 kg.); below this figure the chances of survival diminish rapidly. This is in accordance with the findings of other workers; in the accompanying *Chart* the rates of survival of the Manchester babies are shown graphically; on the same chart the figures obtained for Birmingham by Crosse (1945) and for Warwickshire by Brockington (1944) are plotted. In all curves there is a steeper fall at the 3-3½ lb. level. The effect of *sex* on prognosis is also shown in Table I. It will be seen that the male infant does not stand immaturity as well as the female; but it must be remembered that the average male weighs more than the average female at birth, so that in comparing males with females of the same weight we may be comparing individuals of different degrees of immaturity. The

TABLE II.—Age at Death; Children Admitted for Prematurity to the Duchess of York Babies' Hospital, 1926-38

Age	No. of Deaths	Birth Weight*							
		1-2 lb.	2-2½ lb.	2½-3 lb.	3-3½ lb.	3½-4 lb.	4-4½ lb.	4½-5 lb.	5-5½ lb.
0-1 week	45	6	9	10	10	6	0	4	0
1-3 weeks	47	0	6	10	6	8	8	7	2
3-4 "	23	0	1	3	8	8	0	2	1
4-8 "	44	1	1	5	6	10	6	7	8
2-3 months	18	0	0	2	2	10	2	0	2
3-4 "	11	1	0	3	3	2	2	0	0
4-6 "	2	0	0	0	0	1	1	0	0
6-12 "	2	0	0	0	0	1	1	0	0

* For metric equivalents see Table I.

ages at which the children died are shown in Table II; it will be seen that 60% of the deaths occurred in the first month, and would be reckoned as neonatal deaths.

Ultimate Prognosis

The main studies of the after-histories of immature infants which have been made by other workers are summarized below. The amount of disagreement is disconcerting; the investigators can be ranged in two groups—those who consider that the ultimate prognosis is on the whole good, and those who take a more gloomy view. Among the optimists are Hess, Gesell (1933), Mohr and Bartelme (1930), Levine and Gordon (1942), and Comberg (1927). (With the exception of Comberg's work all these studies were carried out on American children.) Ylppö (1920), Capper (1928), Rosanoff and Inman-Kane (1934), Brander (1937), and Looft, who studied European children, must be ranked with the pessimists.

The disagreement between these groups of workers is probably due in no small measure to differences in the samples died. For example, Hess's extensive observations (250 cases) made on children followed up from his own premature n. These children were seen regularly after "graduation"; they were therefore better supervised than those studied by other workers, who in most cases had not been examined since discharge from hospital, until they were summoned for the investigation in question. Not only did the samples differ but there was great variation in the times and places of the studies. For example, Ylppö carried out his depressing study in 1919, just after the war.

Apart from Illingworth's (1939) work on weights of children who had been immature at birth—he studied out-patients in a children's hospital—there appear to be no observations on the after-history of British children born prematurely.

Method and Scope of Investigation

The work was carried out in Manchester in 1938 and 1939. Three groups of children were studied from the point of view of mental and physical development: (1) children admitted to the Duchess of York Babies' Hospital between 1926 and 1938 on account of immaturity; (2) children immaturally born but admitted to the same hospital for reasons other than immaturity; (3) immature children attending the Manchester child welfare centres. In all, 217 children were followed up.

It was hoped that, in a city the size of Manchester, a large number of immature children would be available for examination; in fact, 1,000 was the target. The follow-up, however,

Summary of Literature

Name, Place of Investigation, and Date	No. of Cases	No. of Children Followed up and Examined	Results and Main Conclusions
Ylppö Germany 1919	668		<i>Prognosis unfavourable.</i> 7.4% of children examined were idiots or imbeciles. 3.1% had Little's disease. They catch up in weight at 4 years. From the point of race hygiene they are not worth saving.
Comberg Germany 1927	97	73	<i>Prognosis favourable.</i> Mental deficiency does not occur in prematurity, even in cerebral haemorrhage; there is no relation between cerebral symptoms in early life and later impairment of intelligence. (Yet 6.8% of her cases were mentally defective, and Terman's figure for unselected school-children is 2.6%.)
Capper Vienna 1928	437	103	<i>Prognosis unfavourable.</i> Of those that survive, the majority are mentally and physically undeveloped. The important cause of death is undeveloped vascular tissue.
Looft France 1931	105	105	<i>Prognosis unfavourable.</i> Among 105 private patients he had 32 "heart conditions," 19 "an"
Mohr and Bartelme Chicago 1930	113	113	<i>Prognosis favourable.</i> Infants compared with full-term siblings; no significant difference in mental development. (Yet 9 had disturbance of reflexes, 9 had strabismus, 14 had "heart conditions," and 3 were mentally retarded.)
Gesell New Haven 1933			<i>Prognosis favourable.</i> Prematurity in itself does not alter marked course of mental development. It carries with it hazards which inflict temporary or permanent penalty. The infant is protected by inherent factors of organic maturation.
Rosanoff and Inman-Kane California 1934	381	146	<i>Prognosis not very favourable.</i> Premature birth is an aetiological factor in mental deficiency, but is not, in itself, a cause of mental deficiency. The damage is caused by cerebral trauma during birth. (10.27% of his cases were mentally defective; I.Q. under 76.)
Hess Chicago 1934	250	250	<i>Prognosis favourable.</i> Boys catch up in weight at 4 years, girls earlier. Children of 4½ lb. (2 kg.) and over gain more rapidly than those under 3½ lb. (1.6 kg.). There is no difference in mental development between prematures and their siblings, except for those injured at birth. Of his 69 cases of intracranial haemorrhage 10 were feeble-minded and 12 were retarded.)
Brander Helsinki 1937	230	230	<i>Prognosis unfavourable.</i> Average I.Q. of prematures lower than that of a non-selected group of children of same age. He says that trauma at birth is more definitely an unfavourable factor than birth weight alone.
Illingworth London 1939	150	150	Compared weights of immaturally born infants with those of normal weight. (Subjects were out-patients of a children's hospital.) 86% of premature series under weight; 34% of control series under weight.
Tow U.S.A. 1942			<i>Prognosis fairly favourable.</i> Majority develop normally but are slow in learning to co-ordinate. Because the premature infant is liable to cerebral
McKee et al. (quoted by Gordon and Levine) U.S.A. 1942			<i>Prognosis favourable.</i> The chances that these infants develop into healthy and fit persons are not appreciably less than those of infants born at term.
Collis and Majekodunmi Dublin 1943	45	38	<i>Prognosis favourable.</i> Premature children will generally grow up normally. (One of his cases had Little's disease, one had right hemiplegia, and 4 had speech defects.)
Bourne London 1943.			The baby of 5 lb. (2.27 kg.) will grow to normal stature in 4 to 5 years; the child of 4 lb. (1.8 kg.) or under will always be small, though it may reach a high grade of mental development.

was disappointing in the extreme: it was surprising how quickly the Mancunians changed their dwelling-places. Reply-paid postcards were sent, advertisements inserted in the Press, and posters put up in shops. The B.B.C. was approached, but could not decide into what type of programme such an appeal would fit. (Capper had a similar experience in Vienna in 1928; he even enlisted the help of the police!) Moreover, the work was interrupted by the onset of the recent war; there was a general scatter to Blackpool, and many children were lost. The study is therefore incomplete.

Scope and Method of Examination

The children's weights and heights were taken and a general physical examination was performed. A medical history was then got from the mother; the children under 3 years of age were tested with the Gesell development schedules, and those of 3 and over with the Binet-Simon (Stanford revision) tests. The results of the Gesell tests were recorded in terms of months below or above average development for age; intelligence quotients were calculated for the older children. In every case the chronological age, and not the conceptional age, was used; the ages were not corrected in any way for prematurity.

The weights were compared with the average weights of children of the same age. A further comparison was made with expected weights. The expected weight of a child at any given age was calculated by subtracting the difference between the birth weight and the average birth weight (taken as 7½ lb = 3.4 kg.) from the average weight for the age. Thus if a 7½-lb. baby is expected to weigh 15 lb (6.8 kg.) at five months, a 5½-lb. (2.5 kg.) baby is expected to weigh 13 lb. (5.9 kg.) at five months. This method of calculating the expected weight is a convenient one, but it assumes that all children, regardless of birth weight, gain at the same rate. This is probably quite an unjustifiable assumption; it is therefore interesting that in this study the children appear to approximate to their expected weights, as calculated by the above methods, while falling below the average weights for their ages (Table III). For example, at 4 years the children are still only 91% of the average weights for their ages, whereas they are 98% of their expected weights. These results do not agree with those of Hess; he says that if age is reckoned from conception the children tend to catch up to the average at the age of 4 years. (This correction of Hess's would give the child at the most the benefit of two months, the conceptional age was avoided in this study because of difficulty in establishing the date of conception.)

It may be argued that the children's weights were compared with standard figures (Holt's), and that possibly the general level of weights of Manchester children might not be so high. When the experiment was designed it was intended to compare the children with full-term children from similar environments. Circumstances, however, made this impossible. In order to find out how nearly the weights of full-term Manchester children approximated to those in the standard tables, averages were taken of the weights of 100 children of each age group up to 5 years. These figures were taken from the records of one of the child welfare clinics. It was found that these averages did not differ greatly from the standard figures; in all cases the Manchester children were a few ounces heavier than would be expected from the tables; if, then, the figures obtained from the immature children had been compared with these Manchester results the percentages of average weight would have been, if anything, slightly lower.

The results of the studies on mental development are given in Tables III and IV. When considering children under 3 years it must be remembered that the Gesell schedules test levels of

TABLE IV—Physical and Mental Development of Children Immaturely Born

Birth Weight*	% of Average Weight for Age	% of Expected Weight for Age	Intelligence Quotient	Developmental Level	No. of Cases
Under 2½ lb	80	92	89	Average	5
2½-3 lb.	85	91	83	~ 3 months	15
3-3½ lb.	86	99	82	~ 2 "	16
3½-4 lb.	86	99	88	~ 2 "	12
4-4½ lb.	91	101	90	~ 2 "	32
4½-5 lb.	90	100	90	~ 3 "	41
5-5½ lb.	90	93	96	~ 1 month	96

* For metric equivalents see Table I.

development, they are therefore not strictly comparable with the Binet-Simon tests, which try to determine with how much intelligence the child has been endowed. It will be seen that the developmental levels of the immature child are, on the whole, not up to the average; it cannot be inferred from this, however, that the children will not catch up. The figures suggest that there is a slowing down of the process of development; this is in agreement with other workers. There is no doubt that standing, walking, and talking are often delayed. (In the Gesell schedules motor characteristics, language, adaptive behaviour, and personal social behaviour are all taken into account.)

The intelligence quotients of the children aged 3 to 6 years inclusive are also given in Table III. The general impression gained is that most of them would not be very brilliant children. Table IV suggests that the higher the birth weight the higher the intelligence quotient is likely to be.

No results of the inquiry into language development are given. The mothers were asked when the children said their first words and when they said sentences, but the mothers' testimonies were considered inaccurate, as they had in many cases only hazy recollections of their children's first efforts at speech. A distinct impression was gained that speech was delayed, this was particularly so in the case of twins and triplets. (The speech delay accounts partly for the low ratings in the Gesell tests in the children under 3.)

Discussion

Do these results contribute anything to the present state of knowledge concerning the ultimate prognosis in immaturity? There are not enough cases to draw any hard-and-fast conclusions, but the tables suggest that in many cases development, both mental and physical, is delayed, that many of the children tend to remain smaller than their fellows—at least up to the age of 6 years—and that most of them will not reach a very high degree of intellectual attainment. But this is very different from Capper's suggestion that they become dull and backward children, and that many of them become candidates for mental hospitals.

The question at stake is: Does prematurity by itself induce a mental and physical retardation? If so, is this permanent? There are four main possibilities with regard to the mental and physical development of the immaturely born child. (1) He may continue to gain at his foetal growth rate until he catches up with the average child for his age. His mental and physical development may then proceed at the same pace as that of his full-time siblings. (2) He may gain very slowly, at a rate less than that of an average child; he may be late in walking and talking. He may, however, catch up eventually in mental or physical development, or in both. (3) His physical or mental development may be retarded, and he may never quite catch up with his fellows. (4) He may develop Little's disease; from this he may partly recover, but it is likely that he will be permanently damaged—he may be feeble-minded or imbecile, and may not learn to walk.

These possibilities will now be considered in more detail.

1. *The Immature Child who Catches Up in the First Year.*—Scammon (1921) is of the opinion that the growth tendency of immatures is in general that of foetuses of the same size and age rather than that of full-term children. He says that, after a short period of retarded growth incident to the adjustment to the extrauterine environment, immatures tend to regain the

TREATMENT OF MUSTARD GAS BURNS*

BY

WILLIAM CLAYTON, D.Sc., F.R.I.C.

ALFRED JOHN HOWARD, M.A.

AND

DAVID THOMSON, O.B.E., M.B., Ch.B., D.P.H.

The desirability of finding a simple yet demonstrably effective treatment for burns arising from contact with the liquid or vapour form of $\beta\beta'$ -dichloroethyl sulphide led us to consider the problem from the physico-chemical standpoint. A careful study of the literature from 1917 onwards has failed to show any marked advance upon the use of Dakin's solution and bleaching powder (CaOCl_2) except that chloramine-T is regarded as more suitable in view of its stability and its non-irritating action.

Very early in the military history of mustard gas it was recognized that its action was most severe on those parts of the human body prone to perspiration. Inexact references to this fact usually mention that mustard gas is lipid-soluble and that this is the key to the enhanced irritant action. Since human perspiration is an aqueous system, probably an oil-in-water emulsion, the term "lipid solubility" lacks precision. What is certain is that mustard gas is only slightly soluble in water (possibly 0.07% at 10°C) but is quite soluble in various organic solvents (notably ligroin, kerosene, petrol, CCl_4 , CS_2) and in animal oils and fats. Its solubility in vaseline and paraffin wax is only slight.

Our basic assumption was that mustard gas was taken up by the skin, especially where perspiration was present, by adsorption, as distinct from solubility. This would account for its rapid take-up by an aqueous system. Anything that would increase the surface activity of mustard gas should accelerate its take-up and enhance its vesicant action. As will be seen later, this assumption receives confirmation when the surface active material lanolin is used.

Two independent types of adsorption are possible in regard to the take-up of mustard gas by the perspiring skin: (1) adsorption due to the extensive interface presented by the capillary structure of the skin, and (2) adsorption on the fat globules present in perspiration.

For any effective treatment of skin that has been contaminated by mustard gas it is necessary, therefore, to recognize the importance of adsorption as a colloidal phenomenon which can attract mustard gas to a given neutralizing agent. The usual method of swabbing with solvent, followed by an application of a paste of vaseline and bleaching powder (with its essentially short time of contact), and finally by scrubbing with soap and water, has obvious defects when considered from the colloidal point of view.

Swabbing with an organic solvent is recognized as of value. The A.G. Ointment No. 1, however, aims at bringing into intimate chemical reaction two materials which are both insoluble in the common vehicle, vaseline. The limited solubility of mustard gas in vaseline, itself entirely inert chemically and from the capillary-adsorption standpoint, is bad enough, but when this is supposed to lead to a chemical reaction with solid bleaching powder presented as a powder suspended in vaseline the whole basis of the scheme is unsound.

We have used chloramine-T throughout our experiments, with the recognition that its chemical behaviour with mustard gas is quite different from that of bleaching powder. Its permanent stability under our conditions, coupled with its non-irritating action, commended itself. Fundamentally, we have aimed at providing a means of adsorbing and solubilizing mustard gas from the skin and exposing it to the action of chloramine-T both in solution and in suspension at the same time. We have used stable emulsions of carbon tetrachloride and of white spirit in either aqueous or glycerol-saturated solutions of chloramine-T.

An inert emulsifying agent was essential and colloidal aluminium hydrate was chosen.

Experiments were made on rabbits. The back of the animal was shaved and then allowed to rest for 24 hours before applying liquid mustard gas from a platinum loop delivering a drop of about 1 mm diameter. A control drop was always allowed to develop without interruption to serve as a datum for com-

FIG 1—Condition of rabbit's back 14 days after application of emulsion for mustard gas burns

FIG 2—Condition of same rabbit 21 days after application. Note complete healing at sites 6, 7, and 8

* This article was submitted for publication on Jan. 15, 1940 and has not been revised to take into consideration any work published since that date.

parison. The animals were photographed after 14 and 21 days respectively.

Two emulsions may be noted from our series:

(X) Glycerol	100 g.	} A
Chloramine-T	18 g.	
Carbon tetrachloride	B

Equal volumes of A and B emulsified. Aluminium hydroxide = 5% of the total emulsion prepared (by weight).

(Y) Water	100 g.	} A
Chloramine-T	10 g.	
White spirit	B

80 parts of B were emulsified in 20 parts of A (by volume). Aluminium hydroxide = 5% by weight of the total emulsion prepared.

Both emulsions were of the oil-in-water type. Both contained solid chloramine-T in excess of its saturated solution.

A lanolin paste was also prepared:

(Z) Lanolin	80 g.
Chloramine-T	20 g.

Intimately rubbed to a smooth cream.

Referring now to Figs. 1 and 2, there are ten points where liquid mustard gas was applied, under conditions as follows:

1. Control (undisturbed)
2. Emulsion Y was applied to the site before mustard
3. " X " " " " " " "
4. Lanolin Z " " " " " " " "
5. Emulsion Y " " 2 minutes after the mustard
6. " " " " 5 " " " " "
7. " X " " 2 " " " " "
8. " " " " 5 " " " " "
9. Lanolin Z " " 2 " " " " "
10. " " " " 5 " " " " "

Fig. 1 represents the conditions after 14 days and Fig. 2 after 21 days.

Certain peculiarities are immediately obvious in the general observations which follow.

(a) Lanolin Z has expedited eschar formation much beyond that of the control. (See Fig. 1, sites 4, 9 and 10.)

(b) Prior application of emulsions X and Y shows a course apparently comparable to that of the control. (See Figs. 1 and 2, sites 2 and 3.)

(c) The later the application of the emulsions after applying the mustard drop the better the result. (See Figs. 1 and 2, sites 5, 6, 7, and 8.)

(d) The time factor observed in observation (c) tallies with in observation (a), sites 9 and 10.

Fig. 2, sites 6, 7, and 8, shows complete healing, emulsion being especially effective.

Discussion

The above results point to the action of mustard gas being a surface effect in the first instance.

The failure of emulsions X and Y when applied in advance of the mustard gas, the enhanced effect of lanolin Z, and the unexpected time factor effect shown in sites 5, 6, 7, 8, 9, and 10 all fall into line if a surface action is postulated, coupled with a solubility factor.

It is important to note that in all our experiments there was no rubbing and no washing off, but simply one application of the emulsion or lanolin and then an undisturbed condition. Undoubtedly a washing-off with emulsion would have given even better results and would probably have disguised the peculiar time effects observed.

We believe our results show that there is a threshold or lag period after mustard-gas liquid is applied to the skin, during which time there is the beneficial factor of evaporation of mustard gas from the increased area of its spreading. Accordingly, in sites 5, 6, 7, and 8 we are still in the lag period of skin attack, and, moreover, owing to evaporation the emulsion subsequently applied has less mustard gas to neutralize.

Anything which concentrates mustard gas locally, as by solution, and therefore by inhibiting evaporation, will either speed up skin attack or resist the action of the neutralizing

agent. Lanolin Z—sites 4, 9, and 10—supports this view, mustard gas being soluble in lanolin and chloramine-T being insoluble in it. Thus there is a localized retention of mustard gas on the one hand and inability of the neutralizing agent to act on the other. Moreover, the known capillary-active character of lanolin (considered as a colloidal material) would hasten penetration through the skin.

Similarly, sites 2 and 3, though not showing the increased severity of sites 4, 9, and 10, fall into line on the theoretical arguments advanced. Mustard gas is localized by solubility in the continuous phase of the emulsion and its evaporation is retarded. Even more striking results in this direction might be anticipated had the emulsions been of the opposite phase-type—i.e., water-in-oil. An obvious point requiring investigation which arises out of sites 2 and 3 is the rate of chemical union between mustard gas and chloramine-T when the reaction takes place in solution.

The above experiments also point to the need for an examination of the actual physico-chemical mechanism by which mustard gas attacks the skin surface.

Incidentally, in light of the above, doubt must be expressed as to the wisdom of instilling a lanolin salve into the eye to counteract mustard gas (see R. Lindsay Rea, *British Medical Journal*, 1939, 2, 881).

Prophylaxis

The data thus far led us to consider the character of an effective barrier to mustard gas to be applied before exposure to the gas. Two ointments were prepared:

(O') Glycerol	50 g.
Chloramine-T	18 g.
Zinc oxide	50 g.
(O'') Glycerol	50 g.
Chloramine-T	50 g.
Sodium stearate	2 g.

Ointment O' was rubbed to a smooth cream; O'' was a gel. Both contained chloramine-T in excess of saturated solution.

FIG. 3.—Condition of a rabbit's back 8 days after application of ointment as a prophylactic against mustard gas burns.

Referring now to Figs. 3 and 4, site 1 is the control mustard application on the back of a rabbit, 24 hours elapsing after shaving. Sites 2 and 3 had ointment O' and O'', respectively.

rubbed in, and five minutes later the mustard-gas liquid was applied as previously described, using a platinum loop. Nothing further was done except to put a lint jacket over the rabbit's body about 15 minutes after applying mustard gas to site 3. The photographs were taken 8 and 23 days respectively after application of the mustard gas. *The marked superiority of ointment O' is shown in site 2.*

FIG. 4.—Condition of rabbit of Fig. 3 23 days after application of prophylactic ointment. The marked superiority of ointment O' is shown at site 2.

Zinc oxide was chosen because of its known value in the so-called S.R. lacquers (sulphur-resisting lacquers) used in the internal lining of food cans. During thermal processing, especially of meat foods, sulphur compounds liberated from sulphur-bearing proteins interact with tinplate to form the blue-purple sheen of tin sulphide, often observed inside cans on opening. Ordinary plain (transparent) lacquer still permits such staining, whereas the same lacquer containing very small amounts of zinc oxide in suspension completely avoids sulphur-staining.

Research is obviously required into the possible chemical neutralizing effect of ZnO on mustard gas, the ZnO being suspended in an aqueous solution (or emulsion in saturated aqueous solution) of mustard gas. However, the barrier presented by ointment O' is now beyond dispute, whatever the actual mechanism of its action.

At the annual general meeting of the Society for Relief of Widows and Orphans of Medical Men, held on May 8, with Dr. R. A. Young, president, in the chair, one vice-president and eight directors were elected to fill the vacancies in the Court of Directors. The annual report showed that the total membership was 282. During 1945 fifty-five widows received relief amounting to £4,837. Each widow over 65 years of age received £75, and those under 65, £60. In addition a Christmas present of £15 was made to each widow. A legacy of £5,000 from the late Dr. Charles Reid, of Stafford, was invested in 2½% Consolidated stock. The invested capital of the society, which is over £140,000, can never be sold and used as income. Many members joined H.M. Forces during the war, and those who have been demobilized are asked to notify the secretary of their present address. Full particulars of membership, which is open to any registered medical man who, at the time of his election, is resident within a twenty-mile radius of Charing Cross, may be obtained from the secretary (11, Chandos Street, Cavendish Square, W.1).

VOLVULUS OF THE SMALL INTESTINE

BY

W. G. KERR, M.B., Ch.B.

AND

W. H. KIRKALDY-WILLIS, F.R.C.S.Ed.

(From the Native Civil Hospital, Nairobi, Kenya)

Volvulus of the whole or part of the small intestine is said to be exceedingly rare in Europe and America. We have had seven cases—all natives of East Africa—during 1945. Braimbridge, in a personal communication, states that in 25 years of surgical practice in Kenya he has found it the commonest cause of acute intestinal obstruction in the native, occurring in more than half his cases. During 1945 there were 21 admissions with acute intestinal obstruction into the above hospital.

Strangulated inguinal hernia	4
Intussusception (all adolescents or adults)	4
Meckel's diverticulum	1
Bands and adhesions	3
Volvulus of pelvic colon	2
Volvulus of small intestine	7

Symptoms and Signs

The age of an East African is seldom exactly given, for he does not know the year of his birth but only the age group to which he belongs. These patients were variously estimated as being between 20 and 45 years old, and they all complained of abdominal pain, distension, and tympanites. The fact that the majority of cases came to hospital within a few hours of onset indicates the severity of the symptoms. Vomiting, usually regarded as an early and severe symptom, was not a feature, and was recorded in only three of our cases. Rigidity usually masked any visible peristalsis, although this was observed in one case. The abdomen was silent in five. Absolute constipation was not an invariable rule; one of the patients had diarrhoea, and one passed blood and mucus per rectum (he had also partial pelvic colon volvulus). One of the patients (the only female) was eight months pregnant, and her pains were at first thought to be labour pains. In her post-operative convalescence she was delivered of a living child. The following table gives a summary of the seven cases discussed in this report.

Summary of Cases

Case	Sex	Date of Admission	Duration of Symptoms	Interval between Admission and Operation	Type	Result
1	M	4/1/45	12 hours	1 hour	Whole of S.I.	Recovered
2	M	24/1/45	1 hour	2 hours	"	"
3	M	14/7/45	36 hours	4	"	Died
4	F	31/5/45	48	20	Combined S.I. and I.L.	Recovered
5	M	26/7/45	4	18	Independent S.I. and I.L.	"
6	M	6/11/45	4 days	24	Whole of S.I.	"
7	M	12/11/45	11 hours	21	"	"

Operative Findings

A right paramedian incision was employed for preference, and the purple distended bowel could be seen usually even before opening the peritoneum. The bowel prolapsed through the wound and was reduced in all by exteriorization and rotation until the mesentery lay straight. There were no adhesions or other apparent cause within the abdomen for the rotation, except in one case in which two tapeworms, each 4 ft. (120 cm.) long, were found tied together in a massive knot at the upper end of the jejunum. Owing to the gross distension of the intestine it was found impossible to return the bowel without preliminary evacuation of the contents. In all cases, therefore, a lower loop of intestine was opened, and a rubber tube inserted through the ring of the purse-string suture. In some cases emptying was satisfactory, but in others the tube was soon blocked by undigested food and had to be removed to allow the contents to be emptied. This was done by milking the contents gently out through the enterostomy. Some gas was present, but in the main the bowel contained

dark-brown fluid with fragments of undigested food—chiefly maize husks or even whole grain. The bowel was heavy, and manipulations had to be done with care. Such manipulations obviously carried the risk of paralytic ileus, but there was no alternative. After thoroughly emptying the bowel, the enterostomy was closed by a purse-string suture; the small intestine could then be readily returned. The abdomen was not drained.

Two of the cases were complicated by rotation of the caecum and ascending colon as well; in one an accompanying volvulus of the pelvic colon was discovered after reducing the small-intestine volvulus. The gut was viable in all our cases; and it is to be observed that we did not find within the peritoneum the quantities of dark blood-stained fluid said to be so typical (Devlin, 1945.)

The female case is worthy of full description.

Case 4.—She was the only woman in the series and, as already mentioned, was eight months pregnant. An upper abdominal incision was made in the midline. Above the pregnant uterus the caecum was found in the left hypochondrium; the ascending colon had a fully developed mesentery and there was a total volvulus of the whole of the small intestine, caecum, and ascending colon. This was reduced and a colostomy made at the lower part of the ascending colon. A tube which had been inserted was soon blocked by whole maize grains and had to be removed. The consequent spilling of intestinal contents soiled the abdominal wound. An oblique incision was made in the right iliac fossa and a fresh tube, passed through this, was anchored in the colostomy opening with a view to binding the caecum in its normal position. On the thirteenth day the upper abdominal wound burst open, but the bowel did not prolapse, owing partially to the use of a prophylactic corset and partially to the plugging of the abdominal wound by the pregnant uterus. Secondary suture was performed, and on the fifteenth day she was delivered of a healthy male child despite the fact that the presentation was a breech with extended arms.

Post-operative Treatment

There was only one death in our seven cases, though the mortality is usually regarded as high (Grey Turner, 1943). We attribute the success largely to the use of post-operative gastric suction combined with adequate intravenous fluid replacement. One of us had treated four cases in the previous five years in small out-station hospitals; gastric suction was not used, and all the patients died. In the present series a Ryle tube was inserted and suction maintained for up to five days, until there was return of bowel activity as evidenced by auscultation or bowel action. Blood or plasma not being available as yet, we used 5% glucose and 0.45% saline—the latter figure being adopted to reduce the chance of pulmonary oedema from salt retention. During gastric suction the patients received one litre of glucose-saline as a basic daily ration, and one litre for every half-litre of gastric contents aspirated. The remaining litres given during the 24 hours were 5% glucose in triple-distilled water. Five out of the seven cases had sulphonamides given orally or by mouth. Some paralytic ileus was common; one case had a burst abdomen, and one patient—died late—died on the fifth day from peritonitis.

Aetiology

There is no reference to the subject of aetiology in those recorded cases to which we have had access. Salisbury Woods (1945), in describing a recent case, refers to 28 cases collected by Rowlands and Turner (1937), and Hamilton Bailey (1940) quotes two cases. This condition, we believe, may well be associated with the dietary habits of the African native. It is his custom to start the day by drinking up to two pints (1.4 l.) of maize-meal gruel in the early morning, and again at mid-day, and then taking nothing solid until the evening meal. In four of our cases the time onset was definitely known as 7 a.m., 9 a.m., midday, and 4 p.m. This sudden distension of the small intestine by thick liquid causes an overloading of one or two loops, which during exertion may become displaced and start the volvulus (Webber, 1945). The resultant spasmodic peristalsis completes the process. In one of our cases, as mentioned, there were, in addition to masses of recently digested food, two tapeworms knotted together, which may have been the starting-point. In volvulus of the sigmoid colon, chronic distension from constipation is generally considered as the *causa causans*; the process in the small intestine would thus appear to be similar. The evidence that such a

large meal may be responsible is confirmed by the findings of McWatters (1945) in 12 cases in India; he suggests it followed the eating of coarse indigestible food. It is to be noted that we also dealt with four cases of acute intussusception in adults. Such cases have been described in Mohammedans by Morro (quoted by Hamilton Bailey in *Emergency Surgery*), and was at first attributed to hunger pains. It should be noted that during Ramadan, Mohammedans fast from sunrise to sunset; then they feast. The sudden gross overloading of the bowel is probably the responsible factor, as in our cases of volvulus.

Summary

Seven cases of volvulus of the small intestine are presented. The condition is relatively common in the East African native.

Reduction is best carried out by exteriorization, and emptying of the bowel by open enterostomy.

The aetiology is discussed; the practice of the African native of taking large gruel meals is held to be the responsible factor.

There was one death from peritonitis. Post-operative gastric suction and intravenous salines are regarded as life-saving measures and have changed the prognosis.

Our thanks are due to the Director of Medical Services, Kenya, for permission to publish this paper.

NOTE BY Sir HENEAGE OGILVIE

During two years of service with the East Africa Force in Kenya, Somalia, and Abyssinia I was responsible for the surgery of an army whose soldiers were mostly Africans—men who lived differently and suffered differently from any patients I had handled before. In learning a whole chapter of surgery that was new to me I was helped beyond measure by the unfailing kindness of the officers of the East African Medical Service; the Director of Medical Services, Dr. Paterson; the Chief Surgeon, Mr. Braimbridge; and the Pathologist, Dr. Vint. Mr. Braimbridge, in particular, instructed me in the methods and guided me through the pitfalls of tropical surgery, and during my spells at General Headquarters, Nairobi, demonstrated his methods and allowed me to help him with operations at the native civil hospital. At that hospital I met the writers of this article—two young surgeons who have the care of a number of beds and perform a weekly operating list that would be the envy of those who practise in London. Their report on volvulus has interest beyond the rarity of the condition in literature and the very creditable number of recoveries they record, for it raises the important question of variations in structure of different races—one as yet hardly touched upon by anatomists or anthropologists.

The African as a patient is cheerful but moody, brave in the face of pain or danger, but terrified of the unknown. He contracts most of the diseases of the European, but to many he reacts differently, and to some, such as peptic ulceration and arterial diseases, he seems to be immune. He has a remarkable resistance to wound infection by pyogenic organisms, and a remarkable ability to repair the effects of trauma. He unites fracture rapidly and seldom suffers from non-union—a complication to which the white settler in Africa seems to be particularly prone. His bodily structure is different from that of the European. Some differences are known—that his skin is more pigmented and richer in sweat glands, that his tibia is longer in proportion to his femur, that his cranial vault is thicker. Others are suggested by his reactions to trauma; for instance, the extreme rarity of injuries to the menisci of the knee, though every kind of osseous fracture and ligamentous tear is encountered, suggests some structural differences. Others again, particularly those of the abdominal viscera, are commonly observed but not recorded. South African anatomists have told me that the African small intestine is usually several feet longer than that of the European, and Vint also believes

this to be the case. The appendix is longer, the stomach larger but not otherwise different. The mesentery is either longer or more extensible, for at laparotomy or necropsy the intestines can be lifted more easily to the surface for examination or manipulation. Anomalies of intestinal rotation and fixation are much more common, particularly the persistence of unfixed mesenteries. It is possible that it is in this greater mobility of the alimentary canal rather than in his dietary habits that the reason for the proneness of the African to volvulus is to be found.

Medical Memoranda

Leukaemic Infiltration of the Site of Herpes Zoster

Leukaemic infiltration of the site of the vesicles of herpes zoster is rare enough to justify the following case record.

CASE REPORT

A ship's engineer aged 52 had had no serious illness until August 1945, when he developed a typical attack of herpes zoster, affecting the tenth dorsal segment on the left side. On admission to hospital it was noted that he had enlargement of the spleen and of the lymphatic glands in the neck and axillae. A blood count confirmed the diagnosis of chronic lymphatic leukaemia. His herpes subsided but raised thickenings were left on the skin and biopsy of one of

them demonstrated leukaemic infiltration. Two months later he was invalided to the United Kingdom and admitted to Rookwood Hospital, Worcester.

On examination his general nutrition was good. The mucous membranes were pale, and large discrete glands of soft consistency were present in the anterior and posterior triangles of the neck, both axillae, and the inguinal regions, the spleen being enlarged to four fingerbreadths below the costal margin. In the distribution of the left tenth dorsal segment the herpes zoster was seen. All the vesicles had healed, but their sites were marked by raised thickenings in the skin of a coppery colour. These are shown in the accompanying photograph. Blood investigations revealed Hb, 78%, red cells, 3,650,000 per cmm, C.I., 1.05, leucocytes 138,700 per cmm (lymphocytes 63%, lymphoblasts 27%, neutrophils 4%, monocytes 1%).

I am indebted to Sir Walter Haward, Director-General of Medical Services, Ministry of Pensions for permission to publish this case.

Reviews

A CHARTER FOR HEALTH

A Charter for Health. By a Committee of the British Medical Association. (Pp. 95, illustrated 6s.) London: George Allen and Unwin.

This little book has been written by members of a committee of the British Medical Association under the chairmanship of Sir John Boyd Orr. Its purpose is to give to a more intelligent section of the public, especially those interested in social and current political problems, an outline of a representative medical view on promoting better physical and mental health in the people of this country. The basic concept of the writers seems to be that the health of the community is, and will be just as good as the present standards of living and education will allow.

The approach is not to the prevention of specific sicknesses and diseases are seldom mentioned except as illustrative examples, rather the object has been to stress the need for raising the whole economic and social level and improving the physical and mental background of the entire population to a level at which the vast majority can enjoy to the full their span of years without serious risk of breakdown, whether physical or mental. Chapter headings such as 'The Essentials of Health', 'The Role of Medicine', 'The Family', 'The Home', 'Food', 'Occupation', and 'Recreation' indicate the scope of subjects on which the medical profession's beliefs are expressed.

In dealing with all these subjects the writers refer back again and again to the need for the economic stability of the family at a higher level if the growing members are to have a proper background in which to grow up to full and balanced physical and mental stature.

As is inevitable but right the whole emphasis is on the needs of children as opposed to the present generation of adults. Education of girls for their future duties as wives and mothers, education designed to lessen the difficulties of personal relationships and education towards assuming a great responsibility in the community are all stressed. The need for a wider planning of education includes a plea for more recreation without restraint of the child and a lighter burden of lessons and home work for the older child.

Perhaps a little overlapping in subject from chapter to chapter has resulted from the large number of contributors but this fault emphasizes the very importance of the repetition. A feature of the book is the excellent modern photographs which serve as illustrations. The opinions expressed are authoritative and sound. The text is clear and well written. It is to be hoped that it will reach in large numbers the public for whom it was designed.

A TEXTBOOK OF NEUROLOGY

Clinical Neurology. By Bernard J. Alpers, M.D., Sc.D. (Pp. 797, illustrated 85.00.) Philadelphia: F. A. Davis Company, 1945.

Dr. Alpers, professor of that subject in Jefferson Medical College, Philadelphia, has given us an admirable new textbook of neurology. A fairly large book, it is unusual among texts of this sort, for it is both pleasant to read and accurately informative. It is pleasant to read because the author presents his material in a systematic manner, it is well written, there are plenty of good illustrations and diagrams, and the general production is excellent. The first two hundred pages deal with the basis of neurology, and there are chapters with headings such as 'The Interpretation of Neurological Symptoms and Signs', 'The Topical Diagnosis of Nervous Disease' and 'Headache, Vertigo, Coma and Pain' which precede more orthodox chapters in which related groups of diseases are described. Dr. Alpers has used the didactic medium, avoiding references and bibliographies, and he has managed to give a general presentation without that rigidity of description which is found in the smaller texts. In one place he says, for example,

All forms of meningitis have features in common, an understanding of which is helpful in treatment and prognosis, and then he goes on to discuss those features before describing the individual diseases. His book cannot well be used for reference, and it is large by the standard of student textbooks in this country, but it is so pleasant to read that most clinical workers who come into contact with neurological problems will enjoy it and benefit by it.

OPERATIVE ORTHOPAEDICS

Anatomical Atlas of Orthopaedic Operations. By L. S. Michaelis, M.D. (Pp. 67; 73 illustrations. 25s.) London: William Heinemann Medical Books Ltd. 1946.

As an example of post-war medical book production the publishers are to be commended, but we doubt the wisdom of producing, however well it has been done, a sketchy outline of operative orthopaedics much of which is based upon the published writings of well-known authorities. Furthermore, there is a deficiency in matters which are of much greater importance than descriptions of operative procedures. What the young surgeon needs to know is when to do a certain operation and what the results of the various methods have been in the hands of a surgical master. In orthopaedics this has already been well done by Steindler, and we await the same approach by a British master.

Dr. Michaelis betrays parochialism when he states that lumbo-sacral laminectomy for a prolapsed intervertebral disk is becoming the most frequent occasion for orthopaedic surgery of the spine. This may be so in his own hospital, but is not at present universal. The present phase—one might almost say "craze"—for such operative intervention has yet to be proved right. In illustrating the procedure for this operation the author has been betrayed by his illustrator into accepting a very obscure picture (Fig. 55) which is out of proportion. A novel method of illustration is employed throughout and it is good. The absence of labelling anatomical structures gives a better sense of reality, but occasionally it is confusing when the text does not explain; as, for example, in one of the illustrations of an approach to the elbow-joint. Arteries are sometimes red and sometimes purple—which is difficult. It is about time that surgical writers ceased to pander to the conservatives who refuse to recognize an anatomical nomenclature upon which medical men have been educated for at least thirty years. The author should not have accepted Fig. 30, which shows the lower portion of the Smith-Petersen incision for the hip-joint tailing off downward and backward towards the ischial tuberosity, nor would a good teacher have omitted to mention the important landmark to the hip-joint provided by the tendon of the rectus femoris and of its reflected portion. Proof-reading could have been better. Phraseology is sometimes involved. Langdale and Kelham are one person. Brigadier Bristow is of course well enough known not to worry about the correct placing of his initials.

In spite of what the author says, no book can provide "a set of tools." It may provide a guide; but the best guide in operative technique for the would-be orthopaedic surgeon is personal instruction by a master. This book could, with suitable modifications, provide a valuable companion for the rentice.

THE SULPHONAMIDES IN OTO-RHINO-LARYNGOLOGY

Les Sulfamides en Oto-Rhino-Laryngologie. By J. Terracol. (Pp. 184. 140 francs.) Paris: Masson et Cie. 1945.

Prof. Terracol has devoted a whole book of 184 pages to the sulphanilamides and the related chemical compounds. About one-third is given to a general description of their chemistry and clinical application, and the remaining two-thirds to their use in oto-rhino-laryngology. It is not surprising that in the latter two-thirds this has involved the author in much repetition and the quotation of many repetitive papers and case reports, which sometimes obscures the main issue. His real thesis is to be found in the two short chapters in the general section in which he insists on the responsibility involved in prescribing and using these drugs, the need to observe strict standards of dosage, and not to ask of chemotherapy what it cannot perform. The author shows clearly how much harm can be done, particularly in otology, by careless prescribing, inadequate dosage, and lack of clinical supervision during administration. The preparations used in France are apparently more varied and numerous than those now employed in Great Britain, and rubiazol still holds its place in France. Little is now heard of it here, though its great value in the early days of this form of chemotherapy is not forgotten. It is clear that most of the book was composed before France was freed from

the German occupation, though the author had the advantage of studying the nature and uses of these drugs in the relatively unmolested University of Montpellier. His study has been thorough, and exhaustive so far as it goes, and is a valuable guide to the subject, but it is unlikely to exercise any permanent influence, because the subject itself is constantly changing and also because the word penicillin is not to be found in the book.

ON STAVING OFF OLD AGE

Medical Aspects of Growing Old. By A. T. Todd, M.B., M.R.C.P. (Pp. 164. 15s.) Bristol: John Wright and Sons. 1946.

Dr. Todd has long been known as a physician with original ideas. In this book he rightly stresses the importance of postponing the effects of advancing years for as long as possible in a population which is including a greater and greater proportion of elderly people. No one will dispute with him the fact that the prolongation of health and vigour of mind and body into old age depends on the right use of the body and on the disciplining of habits in youth and middle life. The essentials for this purpose consist, in the view of the author, in attention to diet so as to preserve the efficiency of the liver, the assurance of proper oxygenation of the blood and effective return of blood from the capillaries to the heart by breathing and other exercises. The author believes that fats are of no metabolic value in the dietary, though they may be of some benefit as appetizers. He allows butter but eschews milk and cheese. In his view circulatory disturbances are as much or more due to malfunction in the structures concerned with the return journey of blood to the heart, and he points out that clinical emphasis has been concentrated on diseases of the heart and arteries—i.e., on the efferent half of the circulation—but that our knowledge of the afferent half is all too imperfect. He lays stress on nasal sepsis as a cause of pulmonary disease, which he thinks is often mistaken for phthisis, to the great detriment of the patient and the overfilling of our sanatoria. There are sensible chapters on the care of the skin, scalp, and feet, and an interesting discussion on enlargement of the prostate and on chronic vulvitis in old women which he holds responsible for pyelocystitis and partial incontinence.

Dr. Todd is scornful of many traditional opinions and practices, including a great many surgical procedures which he regards, probably rightly, as manifestations of ignorance and failure on the part of the physician. The equating of progeria and Simmonds's disease and of angina pectoris and effort syndrome may astonish many readers, but the book is interesting and stimulating. It is written in non-technical language to allow the layman to read it, and at least it gives concrete practical suggestions which will be of great use to many patients.

Notes on Books

The sulphonamides and penicillin account for more than a third, and drugs used in the treatment of infections account for more than a half, of the abstracts in the 1945 *Year Book of General Therapeutics*. The new weapons against sepsis, venereal disease, and malaria have been of outstanding value during the war, but our armoury is less well stocked to deal with the tasks of peace. We still await an effective oral or delayed-action penicillin which will allow it to be used in the home, and the early promise of streptomycin in tuberculosis appears to have clouded over. Thiouracil is the outstanding triumph in psychosomatic medicine. For rheumatism and dyspepsia, the failing heart and the afflicted mind, there is nothing new to report. The pharmacologists continue their intense preoccupation with drugs affecting the autonomic nervous system, and benadryl, a new antihistamine substance, is of considerable scientific and therapeutic interest. In many ways, then, this able scientific and therapeutic interest. In many ways, then, this yearbook is like a wartime communiqué: the successes are reported, the defeats and losses are left in silence. That is not the fault of the editors, who can only report the year's advances, and this they have done with their usual skill and concision. This yearbook is undoubtedly the handiest account of current progress in therapeutics. It is published in this country by H. K. Lewis and Co. at 18s.

No. 23 of *Proceedings of the University of Otago Medical School* is edited by Prof. J. B. Dawson and published in Dunedin. It comprises ten papers on a variety of subjects, all with one exception reprinted from the *New Zealand Medical Journal*. There are two papers on hydatid disease by Sir Louis Barnett and two nutrition papers—one on New Zealand dietary studies, and the other on haemoglobin levels of a group of school-children in Dunedin.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MAY 25 1946

THE PLACEMENT OF THE DISABLED

We welcome the appearance of a new journal entitled *Occupational Medicine*, published by the American Medical Association and peacetime successor to *War Medicine*. In the first article in the first issue Harvey and Luongo¹ make a useful contribution to the subject of physical capacity in work, of enhanced importance in England now the Disabled Persons (Employment) Act, 1944, has been passed. Harvey and Luongo stress the fact that the satisfactory placement of the disabled is only part of a much bigger problem—that of assessing the physical and mental capacities of candidates for all jobs. The future of industrial medicine is bound up with its success in aiding managements to select employees for specific types of work, in promoting physical and mental hygiene, and in giving nutritional guidance. Successful placement requires an estimate of physical capacity and an analysis of physical requirements for the job; capacity has to be matched with the job. A characteristic of human beings is their variability, both in health and in disease, and much damage can be inflicted on either the disabled or able-bodied from poor selection and placement—damage which is not physical but psychological.

Of disabled persons approximately 25% have surgical disabilities, 25% neurotic, and 50% medical disabilities, the last 75% are the most difficult to place in industry, because it is more difficult to explain their limitations to the management. The Disabled Persons (Employment) Act, 1944, is a well-conceived idea, and its objects must be attained; but, as Agate² pointed out from first-hand experience, the present working of the Act gives cause for alarm. For many years the larger firms in this country have had good medical and social services which have resulted in the satisfactory placement of disabled persons. If an employee of these firms attends a hospital and is found to have some disablement, it is easy to employ him satisfactorily. But the bulk of industry consists of small firms not large enough to provide these services or sufficient variety of jobs for those variously disabled. To overcome this difficulty the Ministry of Labour has appointed to local Labour Exchanges Disablement Rehabilitation Officers, with the Civil Service rank of third-grade officers. These officers could not be expected to understand the complicated problems they are called upon to solve; they are allowed little responsibility, and a family man who may

have had a long illness cannot afford to wait until a low-gear Civil Service machine has found him a job. He therefore has to find employment for himself which is often unsuitable. It is rare for the Ministry to follow his subsequent history. Agate quotes figures from a heart clinic where some 300 cases were followed up over a period of eighteen months; despite the energetic efforts of physicians and almoners only two-fifths were satisfactorily placed, and most of these were employees of big firms. The proportion adequately placed by Disablement Rehabilitation Officers was under 10%.

Another aspect of the Act needs consideration. The Ministry of Labour has power to direct labour to a firm which employs less than 2% of disabled persons: is the Ministry less concerned with directing labour than with finding work for the disabled? The Act defines a disabled person as one who is substantially handicapped in his work. When it comes to registration both doctors and Ministry officials tend to suggest that a disabled man who has been working in a suitable job for many years as the result either of the good medical services of his firm or of his own initiative is not disabled within the meaning of the Act. Obviously this position is untenable. Nobody would deny that a pilot who has lost both legs yet flies an aeroplane with skill is disabled; so why should it be argued that a man with mitral stenosis who has been found a suitable job in the foreman's office is not disabled? If the purpose of the Act is to be achieved the Ministry of Labour and their local Employment Exchanges will have to work closely with, and act on the advice given by, doctors and the social service department in hospitals. The idea that the work of the Ministry of Labour is confidential while that of the hospital is not must be given up: both are highly confidential to the outside world, but they must share their secrets when both parties are working towards the same end.

Harvey and Luongo analysed 5,100 different jobs in the Federal service and assessed their suitability for several groups of disabled persons: 1,323 were found suited to persons with amputation of the thigh, 1,464 for those with foot amputations, while only 50 were suitable for those with amputation of both legs. It was found that the frequency and severity of accidents were lower than those in an able-bodied group of similar age, experience, and occupational characteristics. But this was not the case in those with congenital and orthopaedic deformities of the upper limbs, though the jobs suitable for them were found to number 834. Apart from deformities of the hip, those with deformities of the lower limbs had the same accident incidence as the able-bodied. Suitable jobs for those with deformities of the leg numbered 1,373, of the foot 1,471, though only 46 were satisfactory for those with deformities of both feet. Two groups of medical patients were studied—those with heart diseases and those with pulmonary tuberculosis. It is recommended that the former should avoid occupations involving sudden spurts with unduly slack intervals of rest; they should have regular hours and favourable conditions of work, and avoid extremes of air pressure and temperature. The patient's capacity for economizing his energy should be considered, and a heavy strain on the lower limbs is more

¹ *Occupational Medicine*, 1945, 1, 1.² *Proc. roy. Soc. Med.*, 1946, 39, 163.

easily tolerated than on the upper. No one liable to vertigo, syncope, or "sudden death" should climb ladders, or work near dangerous machinery or at high altitudes. Dusts induce cough and bronchial congestion, and should be avoided by those with mitral disease; any environment likely to favour infection of the upper respiratory tract should be avoided, as should any occupation likely to cause anxiety or emotional disturbance. 1,268 jobs were found suitable for persons with heart disease; their efficiency and productivity compared favourably with those of normal persons; accident rates were slightly more frequent, but less severe. The person with pulmonary tuberculosis, it is advised, should have a job which does not overtax his working capacity, and conditions which might reactivate the disease or expose other employees to danger should be avoided. Obvious conclusions, perhaps, but they need to be stated. 1,328 jobs were found to be suitable for the tuberculous. These were as efficient as the able-bodied, and their safety record was good; but their rate of absenteeism for sickness was high.

A group of patients with disabilities of sensation were also investigated: 1,269 jobs were found for deaf workers in which they could put up a performance as good as that of the able-bodied, but in some instances the accident rate was higher than that of persons with normal hearing. For those hard of hearing 2,179 jobs were found in which the results of work compared favourably with those attained by the able-bodied; again psychological problems in some cases increased the accident rate. Satisfactory jobs—2,080—were found for those blind in one eye; their performance was good but the accident rate high—believed to be due to fatigue. Such persons must be given jobs which do not endanger others, and care must be taken to protect the remaining eye. Fifty-five suitable jobs were found for the totally blind, and they did as well in them as normal persons.

As Agate has pointed out, medical cases can best be placed by a team of doctors and almoners working together and advising officers of the local Labour Exchanges; but this requires much time, and it will be some time yet before highly trained staff will be available. The alternative is a comprehensive job analysis for all occupations, similar to that carried out by Harvey and Luongo. The Ministry of Labour seems to be relying on the spasmodic efforts of individual firms. This is to be regretted, since it will hold up progress.

FOOD YEAST

The animals that supply us with food do not add directly to the world's supply of food: they only concentrate certain nutrients in an appetizing form. They burn the greater part of the complex compounds built up by the plants they eat, and they excrete the nitrogen of the proteins. This nitrogen may be lost; at best, it must be reincorporated in protein by plants before it can again be used by animals. In return the animals provide a small amount of food which is more appetizing and less bulky than much of the feeding-stuffs, and contains relatively large proportions of the indispensable amino-acids, of vitamins of the B group,

and, in the case of milk, calcium and vitamins A and D. From the point of view of the health of the soil or of mankind the transaction is profitable in the long run. But on a short run and for people living on the margin of subsistence it is wasteful. What they need is some process that will supply the values of meat and milk without waste of calories and loss of nitrogen. Yeasts have virtues not shared by farm animals: they do not use up calories in uneconomic activities; they can make proteins and vitamins out of simple ammonium salts and carbohydrates; they actually add to the supply of protein and vitamins. Brewer's yeast is too bitter to be used, on any scale, as a foodstuff; but *Torulopsis utilis*, which has been studied by Dr. A. C. Thaysen and his colleagues in the Chemical Research Laboratories of the Department of Scientific and Industrial Research, yields a product of delicate flavour which can be eaten alone or added to other foodstuffs. This yeast is fed on molasses and ammonium salts, and returns about 60% of the carbohydrate and almost all the nitrogen in the form of protein. The dried product "food yeast" contains, per 100 g., 43 g. of protein, 2 mg. (or 670 i.u.) of vitamin B₁, 5 mg. of riboflavin, 40 to 45 mg. of nicotinic acid, and 4 to 8 mg. of pyridoxine. The amount recommended for human consumption is 1/4 oz. (7 g.) per day. In some cases this amount, when all was given at one meal, has appeared to cause digestive disturbances, but one person ate 64 g. daily for 4 days without ill effects. The amounts of the chief nutrients of the 7 g. of food yeast may be compared with those of one-third of a pint (190 ml.) of milk and with our present approximate daily consumption.

	Protein (g.)	Vitamin B ₁ (mg.)	Riboflavin (mg.)	Nicotinic Acid (mg.)
Food yeast, 7 g. ..	3	0.14	0.35	3
Milk, 1/3 pint. ..	6	0.075	0.28	0.21
Approx. average daily consumption	70 (animal, 33)	1.4	1.5	13

The chief contributions of food yeast are, therefore, riboflavin and nicotinic acid. In experiments on animals the biological values of the protein used as a supplement to a cereal diet proved about equal to that of casein; alone, it proved inadequate owing to its low content of methionine.¹ Its value as a source of the B vitamins was shown in an experiment² on rats, in which over 80% of the diet was supplied by flour, with a salt mixture, vitamins A and D, and casein to supply an optimum amount of protein. Group A were given ground whole wheat, and Groups B, C, and D white flour of 75% extraction with 5%, 2.5%, and 1.25% of food yeast. These flours would contain (in mg. per 100 g.):

	Vitamin B ₁	Riboflavin	Nicotinic Acid	Pyridoxine
Wholemeal ..	0.33	0.23	4.4	0.33
White + 5% yeast ..	0.205	0.335	2.8	0.52
" + 2.5% " ..	0.155	0.210	1.8	0.35
" + 1.25% " ..	0.130	0.14	1.3	0.27

Group B grew faster, Group C slightly faster, and Group D less fast than Group A.

² *Food Yeast: A Survey of its Nutritional Value.* Accessory Food Factors Committee, Medical Research Council, H.M. Stationery Office, 1945.

Biscuits containing 8 g. of food yeast were given to children in rural schools²; their weights increased faster than those of children who were given biscuits without yeast, but there was no significant difference between the rates of growth in height. More details than are given in the report are needed before the full significance of these experiments can be assessed. Food yeast has been used in treatment of vitamin B deficiencies. Subjects who were given 7 or 5 g. daily improved or were cured in the course of five or seven weeks, while little change was seen among the controls.

Manufacture of food yeast from molasses and ammonium salts has been started in the West Indies; the yearly output anticipated is of the order of 2,500 tons,³ which would provide 1,000,000 people 1/4 oz. (7 g.) a day for a year. How could this supply be best used? Peoples in Africa, who formerly depended on yeasts in fermented drinks for their supply of B vitamins, suffer from deficiency diseases since they have changed over to more sophisticated food. Food yeast could restore these vitamins, though in a less interesting vehicle. Even the 3 g. of protein would add appreciably to the value of the diets of people who get a large proportion of their calories from cassava. And food yeast could also be used to make up for the deficiencies of polished rice.

Two per cent. of food yeast can be added to white flour without affecting the flavour of bread made from the flour. This suggests a new way of putting back some of the good which is removed in milling white flour. The latest argument in favour of 73% extraction is that hens do not get enough riboflavin if they are not given whole grain; that we cannot have both our pre-war supply of whole eggs and 85% flour. But putting the yeast into debased flour seems a roundabout process. Why not give the hens the food yeast and leave us our 85% flour? A supplement of 5 to 10% to the balancer meal for domestic poultry-keepers is recommended.

Food yeast is not a magic key to the problem of the world's malnutrition. The daily dose recommended supplies only a fraction of some of the nutrients needed, and the amounts that could be made would supply this dose to an even smaller fraction of the people who lack these nutrients. It would not add the calories that are needed to prevent famines, nor increase the fertility of the soil. The long-term solutions are to be found in the wider use of legumes that put nitrogen into the soil, and in the steps proposed by the World Conference on Food and Agriculture—irrigation, prevention or cure of erosion, use of fertilizers, and a gradual change to mixed farming. But food yeast should mitigate some of the present evils and be a useful adjunct in the future. *Torulopsis utilis* is a token of our new position with regard to food and its production—we now know our wants and can state them in figures, which is the first step towards satisfying them. *Torulopsis utilis* var. *major* is a token of our present powers, for this variety, which can be centrifuged down rapidly, owing to its large size, was not found, but was made by treatment with camphor.

SALMONELLA INFECTIONS

A year ago¹ we discussed salmonella infections and their distribution in Nature. A recent paper by Hayes and Freeman² shows the types of salmonella met with in the Army in India. With the exclusion of *Bact. typhosum* from consideration, 548 strains were sent to the Central Military Pathological Laboratory over a period of four years. They were: *Bact. paratyphosum* A 281, *Bact. paratyphosum* B 7, *Bact. paratyphosum* C 110, *Bact. enteritidis* 111, *Bact. enteritidis* var. *dublin* 14, *Bact. typhimurium* 18, miscellaneous 7. The infrequent occurrence of *Bact. paratyphosum* B is remarkable. It is a rather rare salmonella in India, though in Great Britain it has become in recent years the most frequently identified salmonella type.

Infection with *Bact. paratyphosum* A does not reveal any "marked aggregate variation" which cannot be accounted for by the increase in the size of the Army in India over the four-year period. But *Bact. paratyphosum* C and *Bact. enteritidis* infections showed a significant rise. The *Bact. paratyphosum* C strains all contained the Vi antigen of *Bact. typhosum*; in 1944 only seven were isolated from Europeans, the remainder being from Indian patients. Increased infection with this strain may be due to the wartime movements of various people. This strain is not uncommon among the Chinese. *Bact. enteritidis* was isolated direct from the blood of infected persons in 87.5% of cases, and from the faeces in only 4%. Definite septicaemic invasion could be postulated for nearly all these cases, and not the ordinary clinical type with gastrointestinal symptoms without blood invasion. This gastrointestinal type used to be the prevailing, indeed almost the invariable, form in Great Britain up to fifteen or twenty years ago, but over the past few years there have been reports of many cases of salmonella infections resulting in a septicaemia with a high mortality. Usually they appear not in outbreaks but as isolated cases, with no indication as to the source of the infection and without demonstrable relation to other cases. In Hayes and Freeman's series practically all the strains are from cases of septicaemic type. Unfortunately the clinical and epidemiological details of the cases from which the strains were derived were not available to the laboratory. No facts are given to show if most of them were single cases or cases from limited outbreaks, or if any or many of them were associated with outbreaks of ordinary food-poisoning. As might be anticipated from the high proportion of septicaemic cases, the mortality was high (5 to 10%), compared with 1 to 2% for the food-poisoning clinical type.

We know that the septicaemic type of infection with salmonella strains appears to be on the increase in this country, and this increase seems to be even more marked in India. There is some not very clear-cut evidence that persistent high temperatures may affect invasive properties, and it would be of interest to study the relative prevalence of salmonellas associated with septicaemia in countries with high average temperatures. Hayes and Freeman put forward some interesting suggestions to account for this increased invasive quality of *Bact. enteritidis*, such as the acquisition by mutation of a "virulence" antigen analogous to the Vi antigen of *Bact. typhosum*, or by the development of a high degree of host adaptation. In this connexion it should be noted that *Bact. typhimurium* was isolated in only 18 cases, and in most of them from the blood. This is the commonest of all salmonellas as regards its distribution and prevalence. *Bact. enteritidis* (*dublin*) was isolated only on 14 occasions, and it would be useful to know how

³ Food Yeast: A Venture in Practical Nutrition. Colonial Food Yeast, Ltd., 1944.

¹ British Medical Journal, 1945, 1, 451.
² Ind. J. med. Res., 1945, 33, 177.

many of these cases were associated with cattle or were infected by milk. There is still an urgent need for closer co-ordination between clinical, field, and laboratory findings, so that the relation between specific types, the sources and reservoirs of infection, and the clinical manifestations can be established more clearly.

HABITUATION TO STREPTOMYCIN

We continue to hear about streptomycin from American sources before there has been any opportunity to test its therapeutic powers in our own patients. Some of the latest news is disquieting to those who had hoped that it would fill some of the gaps left by penicillin. One of its drawbacks has been pointed out by E. P. Abraham and E. S. Duthie.¹ Streptomycin is a base, and in a medium on the acid side of neutrality its activity falls steeply. So far there is no clinical counterpart to this laboratory observation, but more direct evidence of a weakness in its potentialities comes from authors who have observed a rapidly increasing resistance in bacteria exposed to its influence. By cultivation on media containing increasing concentrations of streptomycin, C. P. Miller and Marjorie Bohnhoff² were able to produce a startling increase in the resistance of gonococci and meningococci, which after only four to six transfers withstood a concentration of 75,000 units per ml.—“the maximum concentration which could conveniently be employed with the supply at our disposal.” By the same method they lifted the resistance of a gonococcus to penicillin to nearly 10 units per ml. Although this was a much more laborious process its results must presumably be taken as a warning against the idea that penicillin will necessarily continue indefinitely to cure nearly every case of gonorrhoea.

C. W. Buggs and his colleagues³ cultivated 212 strains of various species of bacteria from patients before and during treatment with streptomycin. They found not only a wide variation in initial susceptibility in some species but a tendency to the rapid acquisition of resistance. In one patient the concentration of streptomycin inhibiting the growth of a streptococcus responsible for a urinary tract infection was in successive examinations 1, 2, 4, 8, and 256 units. Streptomycin may have to be given in very large doses, ensuring an early lethal effect, if this escape from its influence is not to occur. Possibly because of the high concentration maintained in the bowel, owing to minimal absorption, no such habituation was evident in the studies of Dorothy G. Smith and H. J. Robinson⁴ on the effect of oral streptomycin on the intestinal flora of mice. It clearly excelled streptomycin, sulphasuxidine, and sulphaguanidine in suppressing coliforms, and achieved its effect rapidly. Evidently streptomycin may be of value as an intestinal disinfectant before operation on the colon.

THE SPA IN THE FUTURE HEALTH SERVICE

Ten spas were represented at a conference held by the British Spas Federation in Harrogate at which Lord Horder gave an address and was re-elected president. Pointing to some omissions from the National Health Service Bill, Lord Horder noted the Government's silence about utilization of the British health resort and about the large group of patients suffering from rheumatic diseases. Something would be done, he suggested, in proportion to the standard reached by the health resorts. The standard must have at least two desirable features. The first was linkage with

groups of people who could investigate and carry on research: there must be liaison between the spa and the teaching centre. Secondly, the lay-out at the spa must be such as to cater for the potential or actual patient, with medical control by doctors who were spa-minded—which meant that the doctors should have expert knowledge of what was possible in the spa where they practised. If these two conditions were properly observed, Lord Horder said, then no Minister would dare to neglect the inclusion of British spas in any scheme which he put forward; and by regulation he could contract out certain aspects of national health. He himself would add to the spa some definite amenity for the patient's private life—amusement, and mental and physical recreation. Prof. J. S. Hartfall, of the School of Medicine, Leeds University, advised the spas to plan regionally without delay. They must not forget industrial rheumatism, he said, nor the need for research and for co-ordination with other spa centres and university centres. It seemed clear to him that the reputation of the spas depended upon the quality and repute of their doctors, together with up-to-date facilities for physiotherapy, including hydrotherapy, and hospital facilities for rehabilitation. If these things, and in particular research, were attended to then spa treatment as an established feature of medical therapy would have a place in the future national health service of this country.

G.M.C. ELECTION

In accordance with the Medical Act, 1886, an election of five members of the General Council of Medical Education and Registration of the United Kingdom to represent the registered medical practitioners resident in England and Wales is about to be held. By the appointed day, May 20, the following had been duly nominated as candidates for election: Louis Francis Beccle, South Woodford, London, E.; John Wardle Bone, Luton, Beds; Albert James Clarke, Kentish Town, London, N.W.; Harry Guy Dain, Selly Oak, Birmingham; William Fraser, Currock, Carlisle; Edward Andrew Gregg, London, N.W.; Leslie William Hefferman, West Cross, Swansea; Sir Ernest Kaye Le Fleming, Wimborne, Dorset; William Macleod, Consett, Co. Durham; James Edgar Outhwaite, Yeadon, Leeds; William Walters Sargent, Sutton, Surrey; Gordon Reginald Ward, Sevenoaks, Kent; Noel Everard Waterfield, Little Bookham, Surrey.

At the Annual Representative Meeting of the British Medical Association held in July last the selection of practitioners who will have the support of the Association in the next election of Direct Representatives for England and Wales to the General Medical Council resulted as follows: Dr. J. W. Bone, Dr. H. Guy Dain, Dr. E. A. Gregg, Sir Kaye Le Fleming, Dr. N. E. Waterfield. Their joint election address is published in our *Supplement* this week at page 154.

We regret to announce the death of Dr. T. H. Bryce éméritus professor of anatomy in the University of Glasgow.

The sixth annual general and scientific meeting of the Ophthalmological Society of Australia will be held from Oct. 23 to 26, 1946, at Melbourne. The president of the society, Dr. J. Ringland Anderson (108, Collins Street Melbourne, C.I.), states that practitioners from this country who may be able to attend the meeting will be welcome. The organizing secretary is Dr. W. D. Counsell (85, Spring Street Melbourne, C.I.), to whom communications should be addressed. The Secretary of the B.M.A. will be glad if any member contemplating attendance at the meeting will write to him.

REHABILITATION IN SCOTLAND— ADVISORY COMMITTEE'S REPORT

"Rehabilitation of the sick and injured means the process of restoring them in the greatest measure possible to health, working capacity, and social independence. In that sense it includes all medical and surgical treatment, all assistance of whatever kind given to a patient during his incapacity and, where necessary, his specially arranged reinstatement in an appropriate occupation." This is the broad definition of rehabilitation adopted by a subcommittee, under the chairmanship of Prof. E. P. Cathcart, of the Medical Advisory Committee (Scotland), which is presided over by Sir John Fraser.

The recently issued report of this committee stresses that in all cases where recovery or partial recovery may be expected the rehabilitation of the patient is as much a part of medical responsibility as is the primary treatment. A wider and more judicious use of rehabilitation measures would reduce the duration and degree of the incapacity which patients suffer. Surgical and orthopaedic witnesses who gave evidence before the subcommittee were agreed upon the value of the more remedial as distinct from the diversional forms of occupational therapy, particularly for lesions of the upper limbs. A considerable range of occupational activity has been found useful as part of the programme of re-education and reorientation in the particular types of case which are encountered in the more specialized departments of neurology and plastic surgery. An important recent development is illustrated by schemes such as that which is being carried out in Birmingham by the Austin Motor Company in collaboration with the Birmingham Accident Hospital. A workshop has been established in which, under the supervision of the surgeon, injured workmen are given specially selected jobs of work designed to exercise the injured part. Such a scheme has the twofold advantage that it provides a type of occupational therapy which bridges the gap between medical treatment and full return to industry, and by suitably graduated wage scales it gives an incentive to continued progress.

The Gleneagles Experiment

Since 1943 a special experiment has been in progress which provides a residential rehabilitation centre for patients referred from hospitals and, in some cases, directly from general practitioners. The Fitness Centre at Gleneagles was set up at the request of the Ministry of Fuel and Power and the Miners' Welfare Commission, in the first instance for providing rehabilitation for miners, though its scope has since been extended to a wider range of patients. The Gleneagles project has served as a useful experiment in rehabilitation which has attracted much public attention. The actual medical measures used have undoubtedly proved valuable in increasing physical fitness, and have been studied with interest. Notwithstanding the excellence of the work done by Dr. P. J. Macleod and his staff, however, it has to be recognized that the experiment has not been completely successful, in that all that might have been expected in hastening return to work has not been found possible. The reasons for this are partly the inadequate selection of cases for admission; partly the deterrent effect which the prospect of compensation still has; and partly the special difficulties of the mining industry, including the policy (in the subcommittee's view a mistaken one) of segregating miners.

The report goes on to state that "the final stage in rehabilitation is re-employment, and remunerative work is often the best form of rehabilitation." And in this connexion:

"It seems to us that in future doctors as a whole, whether employed in general practice or in hospitals or in clinics, should have a better knowledge of the conditions under which their patients work, and of the broad principles of industrial medicine. The family doctor will still have most of the responsibility of the return of his patients to work. We believe that his problems and anxieties in this connexion would often be lessened if he took an active interest in the industries within his area and obtained first-hand knowledge of the conditions under which his patients work. We feel sure that industry will welcome doctors who seek in this way to enhance their professional competence."

Fundamental Principles

Before considering the nature and extent of the further facilities required the subcommittee lays down three fundamental principles.

"In the first place there must be, so far as is possible, continuity of supervision during the whole process of primary treatment and rehabilitation. In most surgical and orthopaedic cases, rehabilitation must be started within the first few days in hospital, and should be carried on throughout the whole period of sickness and convalescence. At this early stage the patient has to be educated and encouraged to take an active part in promoting his own recovery. Unless there are clinical indications to the contrary, stress should be laid upon active as opposed to passive forms of treatment.

"The second principle is that the planned programme of increasing activity should continue through convalescence to the point at which the patient is considered fit to resume his normal employment. If it becomes clear that he will be unable to do so, the process of rehabilitation should be designed to enable him to undertake training for some other occupation.

"Thirdly, return to work or entry into a course of training should take place when he is judged to be fit for it. In some instances a brief holiday may be advisable, but occasionally the benefit gained from reconditioning may be lost if the patient is allowed to relax for too long a period before return to work. On the other hand, it may be definitely harmful to set patients to work too soon after discharge from hospital or convalescent home. If their general physical tone is below par they have not been sufficiently prepared by a process of hardening to face the stress of ordinary working life."

Finally, the report recommends the establishment of non-residential centres related to the major general hospitals in the large towns. Each region should have one or more hospitals equipped for the rehabilitation of long-term cases. A smaller number of larger, better equipped, and better organized convalescent hospitals is needed. One large residential centre should be created to deal with about 200 patients. The head of this centre, as of rehabilitation units attached to central or county general hospitals, should be a doctor whose whole time is given to the work. The exact qualifications for such a post cannot be precisely laid down, but a wide knowledge of and an active interest in rehabilitation undoubtedly are essential. These may be found in a surgeon or a physician or an orthopaedic specialist who is prepared to devote himself to rehabilitation as a whole-time task. On the other hand, it may often be of advantage to secure the services of one who has specialized in physical medicine.

In conclusion, it is suggested that for the running of a rehabilitation centre four practical rules should be observed. First, there should be a single medical control. Secondly, the physician or surgeon who refers the patient to the rehabilitation unit must have the fullest opportunity to discuss the appropriate course of treatment with the medical officer in charge. Thirdly, the auxiliary staff must work together as a team under the direction of the medical officer. Lastly, the progress of the individual patients should be reviewed and their rehabilitation programmes adjusted at weekly meetings presided over by the medical officer in charge.

ACHIEVEMENTS OF CHEMICAL RESEARCH

The exhibition of chemical research to be held at the Tea Centre, Lower Regent Street (corner of Jermyn Street), London, S.W., will open on June 5. It is designed to show some of the major achievements of chemical research during the war, and to demonstrate their even greater importance in peacetime. The exhibition is divided into five main sections, each based on a great British chemical discovery.

The section "The Chemist versus Disease" is devoted to the part played by chemical research in combating disease and improving sanitation. Particular emphasis is laid on the sulpha drugs, penicillin, and paludrine, and their significance in chemotherapy is explained. Paludrine is shown in relation to the earlier specifics, quinine and mepacrine. "The Chemist and Your Food" outlines the part played by the chemical industry in modern agriculture. Though this section naturally deals with synthetic fertilizers, it is mainly concerned with the evolution of chemical methods for combating moulds, bacteria, and weeds. Chemical warfare against predatory disease-bearing insects has a section to itself, and the new insecticide "gammexane" is described in detail. The section on "The Chemist and Plastics" centres round "perspex" and polythene. The final section is devoted to "ardil," the wool-like protein fibre made from monkey nuts.

The exhibition is organized by I.C.I. and will open daily from 10.30 a.m. to 8 p.m. (Sundays 2 till 7 p.m.) until June 28 inclusive.

Nova et Vetera

HARVEY AND THE BATTLE OF EDGEHILL

William Harvey is said to have been present at the Battle of Edgehill and, according to the legend, the King entrusted his two young sons, the Prince of Wales and the Duke of York, to the care of that eminent physician. The originator of this yarn was John Aubrey, gossip writer and a charming man, who had only one enemy—himself. He was unreliable, as gossip-mongers have been throughout the ages. The tale originated by Aubrey runs as follows¹:

"When Charles I by reason of the tumults left London, he [Harvey] attended him and was at the fight of Edgehill with him; and during the fight the Prince and Duke of York were committed to his care: he told me that he withdrew with them under a hedge and took out of his pocket a book and read; but he had not read very long before a bullet of a great gun grazed on the ground near him, which made him remove his station."

This anecdote, which has not a shred of evidence to support it, has been repeated by many of Harvey's biographers, and some of them have even elaborated on it. One says that the book he was reading was Fabricius²; another states that Harvey was nearly hit by the cannon-ball; while a third has it that the doctor and the boys had been for a walk and were tired of waiting for the battle to begin, so they sat down in a ditch to pass the time.³ An artist, W. F. Yeames, has depicted the incident in an oil painting, which was reproduced in Ogle's *Harveian Oration* of 1880. This pictures to us the battle in progress in the middle distance. The young princes are crawling up the bank to get as good a view of the fight as possible. The great man himself is seated on the trunk of a fallen tree at the bottom of the ditch, entirely engrossed in the book which he is reading, and he has a second book on his knee. Artistic licence is pardonable in a painter, but is inexcusable in an author such as Eliot Warburton, who is claiming to write history. In his *Memoirs of Prince Rupert* (Vol. 2, p. 17) he writes:

"Whether he [Harvey] was absorbed in the contemplation of his favourite subject [the circulation of the blood], under favourable circumstances or not, is uncertain, but he lay upon the hill side, apparently unconscious of the roar of battle beneath and of bullets plunging into the turf all round him, until he was fairly carried off the field by someone who cared more for him than he did for himself."

How very dramatic, but there is not a word of truth in the whole yarn. If Aubrey's story had stood alone, it would have had to be accepted for want of any other evidence. Fortunately, evidence is available which shows that the young princes were very differently employed that day. First of all, there is the statement of an anonymous writer who, there can be little doubt, was present at the battle, that the cannonade at the start of the fight did little damage, but that a number of cannon-balls fell near to where the King and his children were located,⁴ and this was certainly not in a ditch at some distance from the battle. The story is carried forward by no less a person than the Duke of York himself. He informs us⁵ that the King did not wish to expose his brother and himself to these dangers, and asked first the Duke of Richmond and then the Earl of Dorset to take the boys away from the battlefield. Both these noblemen asked to be excused, as they felt it would be cowardly for them to withdraw while the action was in progress. The King finally gave a direct order to Sir William Howard to remove the children. As they were retiring they were nearly captured by a party of Parliamentary horse, which had come round the left flank of the Royalist infantry. Fortunately, a dressing station had been opened in a barn in this area and a number of Royalist wounded were congregated around it. The enemy cavalry, mistaking these men for a formed body of troops, retired, which gave the princes their chance to escape.

Here are two independent accounts of what happened to the King's sons upon that memorable day; both accounts are in agreement with each other and completely contradict Aubrey's romantic little story.

Sir John Hinton's Account

There is still a further witness, Dr. Hinton, later Sir John Hinton and physician to Charles II. This distinguished doctor had cause to petition His Majesty after the Restoration. In the course of this document Hinton recalls his services at Edgehill, where he appears to have been employed in the intelligence branch of the army and not in the medical one, as might have been expected. He says⁶:

"Your Majesty [Charles II] was unhappily left behind in a large field, at which time I had the honour to attend upon your person, and seeing the sudden and quick march of the enemy towards you, I did with all earnestness most humbly, but at the last somewhat rudely, importune your Highness to avoid the present apparent danger of being killed or taken prisoner, for their horse was by this time come up within half musket-shot in a full body; at which your Highness was pleased to tell me you feared them not and drawing a pistol out of one of your holsters and spanning it, resolved to charge them, but I did prevail with your Highness to quit the place and ride from them in some haste; but one of their troopers being excellently mounted, broke his rank and coming full career towards your Highness, I received his charge and having spent a pistol or two upon each other, I dismounted him in the closing but [he] being armed cap-a-pie, I could do no execution on him with my sword, at which instant Mr. Mathews, a gentleman pensioner, rides in and with a pole-axe immediately decides the business and then overtaking your Highness, you got safe to the royal army."

This extract has been given at length because, if true, it completely demolishes the legend of Harvey acting as the guardian of the princes at the Battle of Edgehill. There appears to be no reason why Hinton's account should not be accepted. It corresponds with the one given by one of the principal actors, the Duke of York. Both agree that the incident took place on the left wing of the Royalist army, that the Prince of Wales ran a grave risk of being cut off by the enemy's horse, and that he was saved only by the fact that they did not charge as a formed body.

Further, dare Hinton have invented such a story? Surely he would not have taken the risk of being exposed as a vulgar liar by his royal master. True, the event had taken place years before, when Charles was only thirteen and his brother James nine. But every incident of his first battle must have been firmly imprinted on his mind. Also, the story can hardly have been invented to flatter Charles II, since it shows him acting rather foolishly and being told so by an older and more experienced man.

George Owen: Physician to Henry VIII

M. E. P. writes: The account of Dr. George Owen by R. R. J., published on March 23 (p. 436), is interesting. R. R. J. quotes Owen's will (1558), and calls attention to the fact that the testator bequeathed to his sonne William "Godde's blessing and myne." Such an expression occurs in the will (1423) of Robert Hylle of Spaxton, who made a similar bequest to his daughter Elizabeth. Owen's legacy in the time of Philip and Mary to Wolvercot Church would be, I think, for prayers to be sung at intervals for his soul. R. R. J. also refers to Dr. Buttes (ob. 1545), who was after the Reformation the first, I believe, to give the title of "nurse" to one who ministers to the sick.

Henry Schuman, of 20, East 70th Street, New York, announces the founding of a new quarterly periodical, *Journal of the History of Medicine and Allied Sciences*, under the editorship of Dr. George Rosen: annual subscription \$7.50 in the United States, Canada, and Latin America; \$8.50 elsewhere. The first number bears the date January, 1946.

Correspondence

The Health Service Bill

SIR,—Most doctors will share Mr. Attlee's recently expressed conviction that "advance comes through co-operation," but we are certainly put in a difficult position by Mr. Bevan's idea of co-operation, which seems to be to antagonize doctors, local authorities, and voluntary hospitals, as well as a very large section of the public. It is further complicated by the circumstance that his "conciliatory" speech bore little relation to the actual Bill or to reason and facts. I quote only one example. Speaking about Health Centres he said: "It has been described in some places as an experimental idea, but we want it to be more than that." Now a thing which does not yet exist must remain an idea until it does, and anything which has not been thoroughly tried out must remain an experiment until it has. All Mr. Bevan's fluency and rhetoric cannot alter these elementary facts or justify his conclusion that "to the extent that general practitioners can operate through health centres in their own practice, to that extent will be raised the general standard of the medical profession as a whole." A Minister who does not distinguish between verbiage and reasoning, or between hypothesis and fact, can make little appeal to those who have been taught the elements of science and the pursuit of truth, so it is only to be expected that the recent Special Representative Meeting should view many of his proposals with disfavour.

A head-on collision between the Minister and doctors and hospital authorities would, however, be a disaster for the patient whom both parties exist to serve. Some basis of co-operation must be found, and as a contribution to this end I put forward the following suggestions, which doctors and hospitals might accept and which the public conscience might approve more than the wholesale appeal to force contained in the Bill, for an appeal to force is itself a confession of failure to understand or of inability to convince.

During the dislocation of war we have come to realize that there must be some sort of regional planning of the hospital service, but there has been no opportunity for hospitals to re-orientate themselves to this idea, and it must be from seven to ten years before buildings can be provided and the needed personnel trained. It would surely be wiser that instead of creating the chaos and resentment inevitable in the Minister's plan to take over all these institutions, as the Bill proposes; this power should be held in reserve and exercised only after 4 or 5 years in cases where a hospital has failed to fit into the scheme or to equip itself properly with any aid the State may afford. This would bring all the governing authorities into active co-operation in the development and working out of plans. Where interest in the hospital is strong, local support would be stimulated and the hospital would retain its own identity within the ambit of the scheme. Where, however, there was no great local support and the hospital was unable to attain the necessary standard the governors would probably be glad to hand over their institution and all the assets of which they are trustees to the Minister. This would avoid the very dangerous precedent of confiscation which the Bill creates, however much we may wish to shut our eyes to it. It would then only be in the very few cases of inefficiency and deliberate antagonism where powers of compulsory acquisition would have to be used. In this way new hospital facilities would be first provided in the neediest areas, as they ought to be. Advance would come through co-operation, but planning could proceed just as surely as if the hospitals had, in fact, been taken over, and in this more gradual process probably even better plans would emerge.

As regards the doctors, an enormous improvement could be made at once in the scope of their service and in freedom from doctors' bills. School-children, dependants of those at present insured, the old-age pensioners, and public assistance patients, etc., could be catered for immediately on the lines of the National Health Insurance, provided a proper capitation fee was paid. Suitable insurance schemes preserving the right to opt out could be devised for the higher income groups if they wished to use them. Increased mileage allowances would stimulate more doctors to go to the rural areas, while something like the "floating sixpence" might be used to attract doctors

to the less attractive or "under-doctored" localities. Provision could be made for doctors who desired to be full-time medical servants to become so, just as some hospitals might come under the direct control of the Minister, but the essence of the service would be flexibility rather than uniformity, and as more facilities became available they would be made free to all. The service would be a growth instead of an administrative machine. It would elicit the hearty support of all concerned, would cater for the infinitely varied needs of a civilized society, and embody two essentials of health—freedom to choose and freedom for development. Dissatisfied authorities and disgruntled doctors are a poor basis for any health service, however nice it looks on paper, and coercion can never take the place of co-operation in getting a job done well. The patient should not be sacrificed to avoid difficulties in administration.—I am, etc.,

Winsford.

W. N. LEAK.

SIR,—The history and present position of politics as related to the medical profession can be outlined as follows. Some years ago our major national policy makers decided on a comprehensive, centrally controlled, and ultimately totalitarian medical service, with the object of increasing their already great power and as an important step towards the completely planned (totalitarian) State. By means of their established control over national finance they obstructed the normal development by organic growth of our traditional medical system, hoping thereby (and it must be admitted not without success) to bring it into disrepute and so prepare the way for what these planners had in mind. It is noteworthy in this connexion that Mr. Aneurin Bevan has put forth his scheme as an attempt to solve financial difficulties experienced by those concerned with medical development and by the public in gaining access to existing services.

The present strength of these aspirants to powers verging on the absolute can be judged from the fact that all the political parties obediently acted in support of the policy which they had laid down. The Labour Party appears to be the more willing tool, but in actual fact there is no essential difference between the policies of the present Government and the last. Under these circumstances it is not to be wondered at that the executive of the B.M.A. yielded to the strong and continuous pressure from outside rather than to the weak and fitful pressure exerted by its own members. (From time to time the "high-ups" of the B.M.A. expressed admiration for the work of P.E.P.—the most powerful planning and policy-forming organization in the country.)

Thus the stage was set for the dishonourable sham fight which has distinguished medical politics throughout the war period and since. In this "fight" the B.M.A. executive and the "representatives" of the profession play the part of combatant, referee, or negotiator as required. The most extraordinary role was that of the now-played-out negotiator. When the suggestion to negotiate with the Minister of Health was first made one, or two small voices were raised in protest against it. Had those voices been listened to the profession might have been saved the humiliation which Mr. Bevan has poured upon it in full measure. Negotiations indeed. Was the profession up for sale? One had hoped not. In any case its fate had been decided whatever the method of execution subsequently agreed upon. Could anything more nauseating be imagined than to have to accept our "enemy No. 1" in the previous House of Commons as our "great protagonist" in the present House? Is it in support of this sorry scheme of things that members of the B.M.A. are being urged to achieve unity—such unity as inspired the Gadarene swine to rush down a steep place and perish miserably in the waters below?

There can be no doubt that the Bill will go through Parliament substantially as it stands and be placed on the Statute Book. Whether it will ever be put into operation is another matter. That depends on how the doctors act. It cannot be born without our help. Sooner or later we must face the question, Are we going to give that help or not? When threatened with compulsion (as we are), since compulsion cannot change the will, lovers of freedom unwilling to co-operate can do no other than defend their freedom with all their might and understanding. With this object in view it is encouraging to know that there is no difficulty in devising a method by which the conscientious doctor can bind himself conditionally to refuse to co-operate without fear of being let down in the time of temptation by his less scrupulous colleague.

Finally, it is important to remember that one of the fundamental principles of democracy—perhaps the greatest—is the freedom to contract out of any proposition that is put before one. This principle is violated in the Bill as it stands. Are we going to submit without a struggle to the remnants of our true democracy being torn to shreds before our eyes? If we do not realize the danger others do and are taking appropriate action. All over the country patients (which here includes "doctors") are forwarding demands to their Members of Parliament to take active measures to ensure their freedom to contract out of the proposed National Health Service. Can the Government turn a deaf ear to this demand? Air-raid shelters were usually provided with emergency exits; concentration camps, so far as one knows, were not.—I am, etc.,

Beverly, Kent.

E. U. MACWILLIAM.

SIR,—These are three criticisms of the Health Service Bill, favourable or unfavourable according to the political bent of the reader's mind, but in any case factual. (1) It is not a health Bill at all but it is one for organizing the treatment of sickness. (2) Under it, family doctors—the patient's own doctor—are to cease to exist as such and to become medically trained State servants. (3) The hospitals, which are all to become State property, are to be conducted by the Minister through appointees whom he sees fit to nominate. The present trustees, governors, boards of management, and municipal hospital committees are to be superseded. Whether or not their present members will be employed depends in the last resort on the Minister. May I comment on these headings in reverse order?

(3) Piety and the sense of public duty created the voluntary hospitals. St. Bartholomew's, begun 800 years ago by Rahere with his Augustinians, continues to-day, under fundamentally the same inspiration, to render irreplaceable service. "Every patient that enters this hospital is entitled to the best-treatment" was in the "charge" with which each officer, including clerks and dressers (students), was admitted. When Henry VIII dissolved the monasteries, St. Bartholomew's struggled on, sustained by little else than piety and the sense of public duty, till (in 1546) the Lord Mayor's appeal to the King, in the dire need of the sick of London, secured the return of a part of the emoluments. Now, 400 years later, all the voluntary hospitals are faced by dissolution. Re-foundation under the broad arrow is to follow: will it carry with it the same piety and sense of public duty?

To return to (2)—the doctors. The advocates of the Bill say the patient will be able to choose his own, and, except that the remuneration of the doctor will come from public funds, their relationship will be the same as before. Such a statement is blind to the facts and to the genesis of the Bill. The germ of this part of it lay in a remark by Sir William Beveridge in a report that he was not concerned with the medical service but that, with payments so large as those provided for sick beneficiaries under such a scheme, the doctors must be so paid that their certification shall safeguard the funds. What else can that mean but that the doctors are to be Government servants and influenced by considerations other than the patient's condition alone? To which of his two masters is the doctor to cleave and which is he to despise?

Criticism No. (1), which is that the Bill is for the treatment of sickness and not a health Bill at all, is not a mere matter of a word. A health Bill's primary concern should be with the Ministry of Agriculture; for, in the words of Sir Thomas Browne (*Religio Medici*): "'All flesh is grass' is not only metaphorically but literally true, for all those creatures we behold are but the herbs of the field digested into flesh in them, or more remotely carnified in ourselves."

To epitomize the enormous subject of the influence of food quality in making or marring positive health, which, the B.M.A. tells us, should be the primary aim of a national health policy, may I quote a couple of writers 300 years later than old Sir Thomas: "In this purse-proud capitalistic age, soil fertility is our own true capital, and soil health the only sure and lasting prop of public health in its widest and truest sense." So the learned editor of the *Medical Press and Circular* says. And Friend Sykes, in *Humus and the Farmer*, published this month (Faber), says: "The health of the world is in the hands of the farmer. If he refuses to learn to farm properly and to understand the biological condition of his soil, then there is no hope either for the livestock industry of the world or for the future of mankind."

This conviction that soil fertility is the basis of public health, the source and stay of positive health, has for years been the concern of the Cheshire Panel Committee, and in spreading this evangel it has had the support of the Cheshire Insurance Committee. In this activity these bodies felt themselves to be carrying out the spirit of "the National Health Insurance Act . . . for the prevention and cure of sickness." While that Bill was under debate in the House I had a conversation with Mr. Lloyd George at his house at Walton Heath, and urged that if the aim were really prevention the clinical services must begin with the children and their mothers before they were born. He said, "This is only a beginning: that is a campaign for the future." But by instituting a panel system, with free choice and not a salaried service, he did, in fact, preserve the family doctor. The present Bill, instead of simply extending medical benefit to the families as Mr. Lloyd George intended and making provision for the techniques, some needing hospitalization, which modern medicine calls for, and for which the B.M.A. has asked successive Governments, throws down Mr. Lloyd George's work, replaces the family doctor by an official, and the people's hospital by a State institution; and for the grand item of positive health does nothing. The means to that end, at which I have hinted, may seem remote, but I think that the preoccupation with agriculture which Mr. Lloyd George evinced in the closing years of his life was due to the fact that he saw them.

That "the prevention of sickness" and the gift—what greater?—of positive health are within the power of a reawakened agriculture to confer in large and substantial part will seem fantastic to many; but the promise and the records are substantial, and in the *Hansard Reports* of the House of Lords debates on Lord Teviot's motion on Oct. 26, 1943, and the Earl of Portsmouth's on Feb. 2, 1944, the grounds of the claim are sketched by master hands.

That a Bill concerned with health, in name at least, should be laid before our legislators without thought of this alleged main factor, one which has been authoritatively laid before the Upper House, shows us that it is a strange world in which we live.—I am, etc.,

Holmes Chapel.

LIONEL JAS. PICTON.

SIR,—I crave the indulgence of your readers to consider a new aspect of the national health scheme. I am tired of hearing and reading of the principles for which we are fighting—fine though they are. It was the patients who voted at the election; they are therefore, we presume, in favour of the present Bill. They asked for it; let them have it. I venture to suggest that the present system of our profession is finished. Let us therefore face the future united, and demand through our Association the best possible conditions (in a like manner to other unions): (1) good working conditions; (2) reasonable hours—a 48-hour week; (3) double the salaries, now suggested by the Interdepartmental Committee; (4) holidays with pay; (5) retirement at 60 on half-pay.

It is demands of this nature that Mr. Bevan and his party understand. Principles and human feelings are understood only by the few, not the masses. If we fight for these conditions we may save something; if we do not we shall lose all. In conclusion I would add that I have nearly 40 years of medical practice before me, not behind me; and, Sir, I am a Conservative.—I am, etc.,

Southsea.

J. T. FURNIVAL.

A Suggestion for Referendum

SIR,—The Health Bill in its present form appears to give the Minister, or subsequent Ministers, dictatorial powers. Though most dictators of any ideology may start with good intentions, fate and human nature seem to bring about their eventual failure, especially in the more civilized countries. Their bad effects are less obvious among the semi-civilized; in fact they may appear as benefactors, where any stable Government is better than none at all. I must apologize for a rather pontifical statement, but it helps to strengthen my argument.

I suggest that many doctors, whatever their inclinations, will be compelled to undertake some form of State service on economic grounds alone, and that a referendum asking whether one would or would not undertake State service is likely to decrease bargaining power. I feel that a referendum on the following lines would be realistic and would carry weight: Will you join an association (one hopes under the B.M.A.) which will guard your interests in cases of unjust regulations, treatment, pay, etc., and abide by the instructions of this association (or union) when it considers that the policy of the health service is contrary to the general good or the rights of an honourable

profession? This association in very grave instances, might advise its members to cease to collaborate in the administrative part of the health service without interfering with its humanitarian aspects. As the members would probably be suspended by the Minister and the receipt of definite fees against the law, patients might be asked to contribute to a general fund to help to tide the doctors over a difficult period. A general breakdown in a public organization would not be viewed lightly by the administrators responsible, the public, or the medical profession.

This suggestion is made in no mischievous spirit but to support my previous statement that unbalanced dictatorial powers in a highly civilized community usually lead to failure, because, even with the best of intentions, errors of commission or omission cannot be hushed up to the same extent or dealt with in other ways as in less civilized communities—I am, etc.

Westgate-on-Sea

F W G SMITH

Compensation under the Bill

SIR—It appears from the Health Service Bill that compensation will be paid only to those doctors who enter the new service. From the Minister's point of view, no doubt, this is sound because if compensation were paid to all then a large number of doctors would accept their compensation, stay outside the service, and do private practice only. But there must be many doctors who on account of their financial position, their age, the state of their health, or because they do not wish to be bound hand and foot by red tape and regulations would not wish to enter the service, but would like to continue doing private work and so maintain their interest in medicine. Is it fair that if they adopt this course they should forfeit all compensation even if their practices are of the type which contain a large number of people who would take advantage of the service?

I am not suggesting that such doctors should receive full compensation, but I maintain that it is only common justice that they should receive a fair percentage otherwise the Minister either forces them to enter his service or confiscates the major part of their practices—I am, etc.

Stourbridge

GEOFFREY DUDLEY

Buying and Selling of Practices

SIR—The medical profession owes a debt of gratitude to the Negotiating Committee, but I cannot think its avowed desire to continue the custom of buying and selling practices, in the circumstances of the Bill, represents the attitude of a majority of general practitioners. The following appear to me important considerations.

1. The incomes indicated by the Spens Committee are considerably below those earned by good doctors, consequently these doctors will suffer an irrecoverable loss when they come to sell—a loss surely unacceptable to those who have purchased with the aid of insurance companies.

2. What would a practitioner have to sell when the Bill comes into operation? The private portion would scarcely be a transferable asset, and besides, a proper introduction would not seem feasible. The purchase of the National Health Service portion strikes me as hardly a good proposition. In short the capacity to develop a practice will be very limited and the chance of deterioration is inherent in the scheme.

3. Without a corresponding increase in remuneration the interest on capital so invested represents a further reduction of income.

* 4. The powers of even negative direction represent an obstacle to negotiating a sale.

In the light of these considerations I feel we should accept compensation as the only fair method of dealing with the problem but press for its payment on the appointed day—I am, etc.

Southport

S H STEWART

"Democratic Medicine"

SIR—Once upon a time an eminent surgeon demonstrated a case to twelve students and at the end of his remarks he asked each in turn whether operation was indicated. All twelve said that it was not but the surgeon said "Gentlemen you are all wrong. I shall operate at 10 o'clock to-morrow." The patient

who was, one may assume, like Dr P G S Davis (April 20 p 624) a believer in "a more democratic system of treatment sprang from the bed saying "No, you ain't, gimme my trousers, twelve to one is good enough for me."

Perhaps Dr Davis did not mean to advocate a system of treatment on these lines, but his words certainly suggest that he did. And, when a man writes about 'buying and selling of the treatment of patients *en bloc*,' one has little difficulty in assuming that he can believe anything, especially if it be impossible. Is it not true that we spoke of selling the goodwill of general practices? There is nothing else the doctor can sell to his successor. We know that patients tend to go to a house that has been a doctor's for many years, but if the service they receive is not to their liking they soon stop doing so, and if that is not (in a reasonable sense of the much abused word) democratic, it is impossible to conceive of what is so—I am, etc.

London W 1

A PINEY

The Minister and Medical Ethics

SIR—If the speech of the Minister of Health on April 30, on moving the Second Reading of the National Health Service Bill as summarized in the *Times* of May 1, is correctly reported he shows a most lamentable lack of knowledge of the ethics of medical consultation. Does he not know that we ought not to see a patient who is actually under treatment by another practitioner without that practitioner's knowledge? And that a medical man who has seen another's patient in consultation must not accept such a patient as his own except in a consulting capacity? I know only too well that this ethical code has not always been observed by a minority of the profession, but it is in our view a right one and in the interest of patients.

Nothing that Mr Bevan can say or that Parliament can do will make a wrong right. I trust, therefore, that Mr Bevan either will be able to explain how his intentions have been misinterpreted or will abandon what appear to be his present intentions in this matter—I am, etc.

Huddersfield

WM BARCLAY

The Population of India

SIR—Sir John Megaw (March 9, p 343) has once more drawn attention to India's most vital problem—her increasing population. The rapidly increasing millions must be the concern of Government, but it is in the sphere of the individual family that the increasing population is experienced most acutely as a problem and I believe that it is in this field that it can and must be answered.

As a typical example, I can think of a family of five children under 11 years old. The father was in war service sending home Rs 30 (£2 5s) per month. The mother was ill and too weak to look after the children properly. She had hookworm and other intestinal infections and her haemoglobin was 30% approximately. Within a month of the birth of the youngest baby two of the others had died of nutritional oedema. This did not occur during a famine. The usual answer suggested to the population problem is education in contraceptive methods—an answer which rouses a storm of opposition on moral and religious grounds, although in my experience the women of India would have no acute objections. But I am convinced that from a purely medical point of view ordinary contraceptive techniques are quite unsuitable for rural India as hygiene is not in the least understood by the people. I believe that the answer is to be found in changing the social customs.

So far as I can ascertain the present custom among the poorer sections of the community is to have intercourse as often as the husband wants it which may be every night and that is regarded by the womenfolk as 'the nature of man.' But I understand that at least among one section of orthodox Hindus a woman is allowed to sleep with her husband only, at certain times and at other times she had to sleep with her mother-in-law or another female relative. Times when intercourse was allowed included, I believe, the third, fourth and fifth days after the end of the menstrual period, that is a little early but possibly includes the fertile period. Certain phases of the moon were also allowed. As a stimulus to increase of population there is in the Jewish Law a parallel regulation forbidding intercourse for a week after the menstrual period and allowing it during what modern knowledge recognizes as the fertile period.

Now, in the light of knowledge gained in the last few years about time of ovulation and the fertile period, it should be possible to make available for those burdened with too many children the reverse custom. The population can be checked only if the method of control has the sanction of religious and social tradition. If Hindu custom has already recognized that certain parts of a woman's monthly cycle are suitable for intercourse and others are not, it seems probable that there should be no great hindrance to absorbing into social tradition the modern scientific discovery of the fertile period. If a couple have as many children as they are able to feed, it should be possible for the wife to persuade her husband to abstain from intercourse during the probable fertile period each month. As the women of India would welcome this knowledge there should be no difficulty in the spread of such a custom where the circumstances require it.—I am, etc.,

Trivandrum, Travancore.

A. W. MEGAW BROWN.

Suprapubic Drainage of Bladder

SIR,—I have been long in replying to Mr. E. W. Riches's letter (April 13, p. 585). In the meantime I have heard of a number of accidents when blind suprapubic puncture was performed, one of them ending in the patient's death. He says the method aims at avoiding a low fistula, but with exposure of the bladder one can, and I always do, strip the peritoneal reflection upwards, and introduce the tube at the highest point on the bladder so exposed and bring it out at the top angle of the wound. This, I think, achieves the same purpose.

Mr. Riches questions the accuracy of my anatomy when I suggest that a tube introduced as he directs must frequently traverse the peritoneal cavity, and quotes anatomists as saying that with a full bladder (15 oz.—425 ml.) the peritoneal reflection is 3 in. (7.5 cm.) above the symphysis. I too can quote an anatomist. Cunningham (fourth edition p. 1277) writes that with distension of the bladder the peritoneal reflection "comes to lie 1½ in. [3.75 cm.], or even higher, above the upper margin of the symphysis." And this is where I usually find it, though of course it varies and may be almost as low as the symphysis. My incision is about 3 in. (7.5 cm.) long, and I cannot remember a case in which the reflection did not appear in some part of the wound. In the only case I have done since Mr. Riches's letter the bladder was well distended by acute retention from prostatic obstruction, and the reflection was about 1½ in. (3.75 cm.) above the symphysis. From careful survey of the parts it was quite clear that a tube inserted by his method would have traversed free peritoneum.

In the case I described there was no question of a pouch of peritoneum slipping down on each side of the catheter as Riches suggests. The symptoms, in the light of the subsequent findings, clearly showed that the trocar had penetrated free peritoneum when introduced. At the time of the prostatectomy the track of the catheter from the parietal peritoneum to the bladder was surrounded by adherent coils of intestine on all sides, and the peritoneal reflection was quite clear of it and well below—level with the symphysis. Though I can see that Mr. Riches's operation has many good points, I still think exposure of the bladder much safer.—I am, etc.,

Guildford

E. W. SHEAF.

The Use of Tuberculin

SIR,—The subcommittee of the Ministry of Health's Standing Advisory Committee on Tuberculosis has stated categorically its belief that exclusion of the Mantoux-negative reactor from tuberculosis nursing is in the interests neither of the nurses nor of the public. That there is a risk to the individual during the phase of conversion is recognized. The extent and nature of this risk in the convert nursing in the wards of a large general hospital has been studied by Daniels. There is, however, no convincing survey of nurses who acquire tuberculin sensitivity whilst nursing the tuberculous, showing the immediate, and late, results. The report of Edwards analysing his results at Market Drayton should have paved the way for other authorities to publish their own experience. The findings of the subcommittee would have been more convincing if they had been prefaced by these facts. Will the subcommittee or its individual members produce the facts relating to the incidence of primary lesions in staff in sanatoria and tuberculosis wards, showing their course,

how the nurse was dealt with medically and administratively, with a five-year follow-up? I should think that Dr. Watt has these facts, or could get them for all the London County Council sanatoria for a number of years past.

It is also stated in your annotation (April 20, p. 615) that the proportion of tuberculin-negative reactors in the population is increasing, and by implication you use this fact to bolster up the case for the negative reactor's being used for tuberculosis nursing. Roughly stated, the less the hazards of meeting tubercle bacilli the longer the primary infection will be postponed. Sooner or later, however, this must lead to the time when there are in the population a high percentage of susceptibles, and then we can expect an increased incidence of florid tuberculosis.

The nurse and her health must come first no matter how our present staffing difficulties press us. We have already delayed far too long, and an investigation with B.C.G. vaccination should be undertaken forthwith.—I am, etc.,

Carshalton Beeches, Surrey.

H. F. HARWOOD.

SIR,—In the annotation on the use of tuberculin (April 20, p. 615) it is stated that "the newer purified protein derivatives of Siebert and Long," which are "extensively used in the U.S.A., are not at present manufactured in this country, but can be imported." Since this statement ignores paragraph 4. of the report of the subcommittee, which is itself unconsciously misleading, it may be worth while drawing attention to the following points:

1.—P.P.D. tuberculins, both "mammalian" (human strain) and "avian," have been issued from the Veterinary Laboratory of the Ministry of Agriculture at Weybridge for the last four years. The issues of each are expected to reach 100 litres per month during the current year, and since the dose for cattle is 0.15 mg. mammalian P.P.D. as compared with the two human doses of 0.005 mg. and 0.00002 mg., this output could correspond to 30–750 million human doses per month. Expressed in terms of solution of potency equivalent to O.T. the estimate is of the order of 900,000 ml. per annum. This probably exceeds the P.P.D. production in the U.S.A., since the position in respect of man and animals is reversed in the two countries. The Bureau of Animal Industry in America still uses heat-concentrated synthetic-medium tuberculin (similar to synthetic-medium O.T.), and P.P.D. tuberculin is made only on a relatively small scale for use in the human subject.

2.—Paragraph 4 of the subcommittee's report states the fact that Weybridge manufactures P.P.D. for veterinary use, but adds that it could not undertake to issue it in sterile tablets of standard strengths. It should, however, be explained that this is not because of any inherent difficulty. It is merely that there is no veterinary demand for it in that form and that tableting machines are not part of existing equipment. The veterinary demand is for solution ready for immediate injection, in which form it is sufficiently stable to assign an adequately long "expiry date."

3.—Production of P.P.D. tuberculin by the Weybridge technique is simple and cheap, and no more troublesome than production of O.T. P.P.D. can also be easily prepared in the dry powder form, stored indefinitely, and issued in any desired form at any concentration. A single kilogramme of the dry powder is theoretically equivalent to 50,000 million 0.00002-mg. human doses, or 200 million 0.005-mg. doses. Despite the large wastage in discarding used phials or tablets this would presumably cover all medical requirements in the country for many years.

4.—Standardization presents no difficulty. There is no variation in potency of Weybridge P.P.D. tuberculin from batch to batch and issues are on a weight-volume basis. A nitrogen determination is sufficient to define the potency, although in practice biological standardization is always carried out on guinea-pigs as well, using a dry reserve P.P.D. as standard. There is no reason to believe that there is any difference in potency between this reserve standard and Siebert's P.P.D., although there has been no occasion to make direct comparison. So far as an "international standard" is concerned the sensible procedure would seem to be to adopt Siebert's reserve stock P.P.D., upon which American medical experience now rests check this very thoroughly against international O.T. (100 guinea pigs, say, statistically treated) for the sake of linking with past British experience, and against a large reserve stock of British P.P.D. as now used by the Ministry of Agriculture. There would seem to be no need to adhere rigorously to one technique of manufacture of P.P.D. so long as equivalence in potency is assured.

5.—In actual practice the Mantoux test with synthetic-medium O.T. is not likely to differ materially from a similar test with P.P.D. solution of equivalent potency, since the probability of non-specific reactions from alien products present is not great at the high dilutions of O.T. used in the test on the human subject. In veterinary practice the test is carried out at such high concentration that almost neat O.T. would be used and the probability of non-specific reaction

tends to be enhanced. The main advantages are that P.P.D. is cleaner and can be much more easily standardized. The common error of biological standardization in an eight-guinea-pig test is of the order of $\pm 40\%$; of chemical standardization is less than $\pm 0.5\%$. Since a \pm error can be additive, one sample of biologically standardized O.T. may have nearly twice the real potency of another unless a large number of test animals is used.

6.—The veterinary problem of diagnosis of tuberculosis is more complicated than the medical one because of the occurrence of "non-specific infections" in the bovine subject. The most common non-mammalian infection in the bovine subject is that of avian origin, and to facilitate differentiation a "comparative test" is adopted, using both mammalian and avian P.P.D. The next most common is Johne's disease. In veterinary work the "specificity" of a tuberculin, as well as its "potency," has to be considered. The current use of human strain P.P.D. for the bovine subject arises from the history of development of testing and may not be permanent.

Detailed discussion of such points is beyond the scope of this letter, but it may be added that P.P.D.s from six different acid-fast organisms are stocked at Weybridge for research purposes, derived from human strains, bovine strains, and avian strains of *M. tuberculosis*, from B.C.G., Johne's bacillus, and the non-pathogenic *M. phlei*.—I am, etc.,

Westlands.

H. H. GREEN.

Penicillin

SIR.—The announcement in the press that penicillin will soon be on sale to the public in chemists' shops, and that refrigeration will be unnecessary, has been greeted with approval in some quarters. To the venereologist, however, it may become a source of serious difficulty. The indiscriminate use of penicillin cream, or lozenges containing penicillin, may perhaps mask the signs of early syphilis occurring on the genitalia or in the throat and may cause either considerable delay in the diagnosis or failure to diagnose the condition. The possibility of an increase in latent syphilis is thus to be anticipated.

Sir Alexander Fleming said at a meeting of the Society for the Study of Venereal Diseases that the question of "fastness" was very important. It was quite easy to make organisms penicillin-fast. One of the great advantages of penicillin was that it was non-toxic, so that when it became available in larger quantities doctors should not be frightened of using large doses. The question of the development of "fast" organisms through insufficient dosage should not therefore arise (*Brit. J. Vener. Dis.*, Dec., 1944). It now seems to me that this problem may become a serious one and that the benefit gained on one hand may be lost on the other. Presumably it is impossible to continue restriction of a preparation which is harmless and is no longer in short supply. Nevertheless practitioners and the general public should be warned of these dangers.—I am, etc.,

W. NEVILLE MASCALL.

L.C.C. (Whitechapel) Clinic.

Jejunal Diverticulosis

SIR.—I was interested in the short report by Dr. A. Klidjian on jejunal diverticulum (May 4, p. 683). I agree that this condition is relatively rare, although I have come across several examples in operations performed for other lesions. Some years ago I opened an abdomen for general peritonitis of uncertain aetiology and found a perforation of a large jejunal diverticulum, the size of a small pear, the point of rupture being situated at the neck and leading to infection of both the peritoneal cavity and the adjacent mesentery. This diverticulum was one of six, all being confined to one loop of upper jejunum, and complete cure was easily effected by resection of the loop and end-to-end anastomosis.—I am, etc.,

Isleworth

JOHN SCHOLEFIELD.

Transient Non-specific W.R.

SIR.—With reference to the article by Dr. J. H. Waelsch on transient non-specific Wassermann and Kahn reactions in a case of infective hepatitis (March 9, p. 353) the following case might be of some interest.

A 74-year-old miller was admitted on March 7 to the medical department suffering from attacks of pain in the right hypochondrium. He was deeply jaundiced and had a temperature of 102.2°F . (39°C). The urine was dark. His history revealed only "Spanish influenza" in 1918. There was no history of venereal disease. The case was eventually diagnosed as cholelithiasis and septic cholangitis and treated with glucose,

insulin, sulphadiazine, and duodenal lavage. He made an uneventful recovery, the jaundice fading in three weeks. The laboratory investigations do not show any findings of particular interest with the exception of the serological results.

On March 8: W.B.C. 12,300; B.S.R. (Westergren) 100 mm.; urine bilirubin $++$; van den Bergh 8 mg.%; blood sugar 94 mg.%; Takata-Ara negative; blood W.R. $++++$; Kahn $++++$; citochol $++$.

On March 29: W.B.C. 6,000; van den Bergh 1.5 mg.%; urine negative; B.S.R. 45 mm.; blood W.R., Kahn, citochol, negative.—We are, etc.,

I. FRIEDMANN.

F. FOR.

General Hospital, Kosice, Czechoslovakia.

Deafness from Rubella in Pregnancy

SIR.—Replying to Dr. Muriel B. Hall's letter (May 11, p. 737) none of the literature published to date suggests that there is any evidence of rubella damaging the unfertilized germ plasma of an ovum, and so causing the congenital defects attributable to this disease. The pathology causing the abnormalities is obscure, but it is thought that as lens and septa formation occur at the sixth to eighth week in the developing embryo, eye and heart lesions are more likely to occur if the disease is contracted about this time, and that the later the disease occurs in pregnancy the less likelihood will there be of any abnormality.

In an article on congenital defects following rubella in pregnancy (*Clin. J.*, May-June, 1946, p. 102) I reviewed the literature since my contribution to the Royal Society of Medicine (*Proc. roy. Soc. Med.*, 1945, 39, 17), and I endeavoured to stress that in earlier cases multiple lesions were manifest in the babe, whose mother had contracted the disease in the early months of pregnancy, and that as deafness *per se* is not discovered until the child is older, many ailments of the child from birth to the time when deafness is manifest could account for that lesion alone. I feel that Dr. Hall's letter tends to complicate the matter still further. The evidence that some lesions are attributable to the disease, although increasing, is not yet proven, and until a complete survey of many cases for many years is available one should not add to the difficulties of arriving at a true assessment.—I am, etc.,

IVOR HUGHES.

Physical Therapy in Mental Disorder

SIR.—The question of the patient's fear of E.C.T. has been very adequately dealt with by Dr. W. L. Milligan (May 11, p. 735). In support of this I would like to add that on my ward round last week I was surprised to be approached by two voluntary patients with a request that they should be given a course of E.C.T. I was able to satisfy them that we did not consider this form of treatment appropriate for them and that other methods were likely to be more helpful towards their recovery. In both instances I found on inquiry that their request arose from observing the increased contentment and great improvement of three other patients who were undergoing, or had recently undergone, a course of E.C.T. with whom my applicants were in daily contact and had naturally discussed this treatment.

It is, I believe, of the greatest importance that immediately before, during, and after the convulsion until full recovery from the shock has taken place no patient should be allowed to see others. I have been told by patients that in some hospitals this is not invariably done.—I am, etc.,

W. J. T. KIMBER.

St. Albans.

Medical Director, Hill End Hospital.

SIR.—Dr. W. Liddell Milligan wonders if I am against combining E.C.T. with psychotherapy. I am not against any scientifically controlled research in our very difficult specialty, but there must be few types of cases which are usefully amenable to the combined attack. Disorders which are of psycho-social origin—such as reactive depressions, anxiety, and hysterical states—should naturally be treated on psycho-social principles; and disorders such as melancholia, which react best to E.C.T., are not claimed as suitable for analytic treatment except by a few rare enthusiasts. Of course, if by psychotherapy Dr. Milligan merely means a hearty slap on the back with cheerful reassurance, I have no doubt that a good suggestive effect is often produced. Indeed it is possible that a considerable number of the good results (unfortunately only temporary)

which follow E.C.T. are due not to the fits but to suggestive forces.

The comparison between the techniques of pushing the button and injecting pentothal is most inappropriate. The latter is followed by a psychological analysis of one hour; the former is followed by an epileptic fit, coma, and confusion, during which any form of analysis is out of the question. I must repeat my warning of the E.C.T. machine displacing psychotherapy. The optimistic view that psychotherapy will not be neglected, will be "combined with" a course of epileptiform fits, does not hold in practice. I have been asked to examine a number of patients who had received courses of E.C.T. in various mental hospitals, from York to Portsmouth, and I carefully inquired whether they had also been given a systematic course of psychological treatment. The answers have invariably been in the negative.—I am, etc.,

Basingstoke, Hants

I. ATKIN.

* This correspondence is now closed.—ED., B.M.J.

Ocular Decompensation

SIR,—This is a subject in which I have interested myself. It seems not many practising ophthalmologists have worked upon Stutterheim's technique in this country. He advocates 24 consecutive sittings and endeavours to raise, and does raise, the kinetic vergence to 80°. I have found that such a sequence of treatments is utterly impossible for private patients under the conditions of modern days. I have found, however, that by limiting the procedure to 6 sittings one can raise a K.V. of 12° and under to 30° or over, and give gratifying relief of symptoms. I aim at giving 12 sittings and can then usually ascend to the fifties, when the effect seems pretty permanent. An occasional "flip up" may always be given if the K.V. falls too low. The treatment seems nearly always beneficial except in cases of neurasthenia, which is in alignment with Stutterheim's experience: "Neurasthenics are unsuitable for this therapy." From practical work in the consulting room I begin to think that the treatment is really a form of suggestion by which the patient is released from inhibited functions. I would suggest in analogy to the relief from the "stickiness" of a stammer. To say that glasses become unnecessary is too large a claim, though such cases occur. I do not quite accept Stutterheim's "fusion centre" explanation, nor the idea of "decompensation" of the present correspondence. As regards nomenclature "kinetic vergence training," to my mind, meets the case.—I am, etc.,

Hastings

GEOFFREY B. LOWE.

Words and Clear Thinking

SIR,—The daily press and almost every popular periodical annoy us with a rich array of words that have been coined mostly in the circumlocution office. I refer to such ugly monstrosities as "in short supply," "hospitalization," "G.I. brides," "key men," etc., etc., *ad nauseam*. Nevertheless, however unpleasant to the ear they have a certain accuracy of description. One hopes to be free from such gargantuan English when browsing in medical literature.

Alas! no. "In short supply" has, I believe, appeared in the *British Medical Journal*, and "hospitalization" is becoming a pernicious disease. However, there is no inaccuracy of meaning here, but imagine my indescribable depression when reading last week's *Journal* as the ghastly word "decompensation" appeared before me (in an annotation on "Examination of the Tongue," May 4, p. 688). I will say no more but quote Sir Thomas Lewis:

"The use of the term 'compensation' at the bedside conjures up or fosters the belief that, by signs derived from the chest wall, judgment upon a balance between dilatation and hypertrophy can be passed; such a belief is grotesque and, in so far as it is believed, it obstructs diagnosis. It is evident that many use the terms 'compensation' and 'broken compensation,' or its ugly equivalent 'decompensation,' at the bedside, and mean no more than to infer that venous engorgement is absent or present; but that is not what is to be understood. A plain observation is garnished with an assumption and served up in an unrecognizable form; this too prevalent habit is pernicious, for it destroys simple and precise habits of thought. Terms involving unproved hypothesis should be eschewed, and in this instance reference should be to the simple presence or absence of venous congestion. By this directness

cumbersome, needless, and in fact erroneous, assumption is avoided, and simplicity and exactitude of expression are secured. The diagnosis of venous congestion is within the easy reach of all; it is a simple expression of what we see. The diagnosis of 'broken compensation,' in its proper sense, is within the reach of none."

Perhaps in future my enjoyment will not be so rudely interrupted.—I am, etc.,

F. R. ELLIS.

Rectal Cancer in Sisters

SIR,—The article entitled "Carcinoma of the Rectum in Sisters" (May 4, p. 683) attracted our interest and attention. It is our wish not to offer comment on the main burden of Dr. R. E. Rewell's remarks but rather to join issue with him over some comments he makes in his last paragraph on the statistical inferences that may be drawn from the evidence he submits.

The author writes, "On any system of probability it is extremely unlikely that sisters will die of the same condition which has a death rate of only 2.3 out of a population of 335,000." Now, since it is extremely unlikely that anyone will die of this condition, it is tautological to state that it is extremely unlikely that sisters will die of it! On the other hand, it is unsound to infer from his evidence that the probability of sisters figuring among the recorded deaths is small according to any system—whatever this unfamiliar phrase may mean. This probability depends on the actual number of deaths recorded for the period over which statistics are available, and on the "sister rate," or probability that a given woman has a sister. It does not depend directly, as the author seems to suggest, on the death rate from the disease. Neither of the statistics necessary for judging the probability of the relevant hypothesis (namely, that sisters are disposed to figure higher among the recorded deaths than would be expected through the random operations of pure chance) is given by the author.

The paragraph in question continues, "There would appear, therefore, to be statistical support for the contention that the conditions found in these women's colons were in some way connected. . . ." To derive statistical evidence for a hypothesis, as large a sample as possible should be subjected to quantitative examination. The rarity of deaths from the condition under investigation does not render it unnecessary to take such a sample; it simply renders it more difficult and more tedious. The death rate from the condition in no way affects the statistical support which can be derived for the hypothesis, which is concerned solely with those who die from the disease and is independent of the number which do not.

We have avoided, in our remarks, the more technical points which arise in assessing the validity of the hypothesis—such as the necessary tests of significance, estimations of standard errors, and assessment of *a priori* or existence probability of the hypothesis. We have also avoided discussion of the very important difference between probability and statistical theory. We have, however, tried to show the danger of jumping to statistical conclusions despite the lack of the requisite evidence. On the evidence submitted by the author, we could adopt similar lines of argument to his own and arrive at the startling conclusion that girls whose names contain the letter "d" are more likely than others to contract carcinoma of the rectum resulting in death.

We apologize for occupying so much of your space with this matter; but just as it has become axiomatic to recognize the important role which statistics may play in the service of medicine, so is it all the more necessary to guard against the danger of misusing this powerful weapon.—We are, etc.,

P. J. HILTON.

S. M. HILTON.

London, N.W.8

The Future of Nursing

SIR,—At a time when there is a shortage of nurses and the demand greater for the social schemes that are being planned, we seem to be likely to lose even those who have been trained. It is all a question of money. A staff sergeant recently demobilized from the R.A.M.C. and anxious to take up male nursing was informed that no R.A.M.C. experience will count in civil nursing. It will take him three years to qualify. He could now command 72s. a week, and when qualified 90s. a week, but would work for long hours. Being a married man with a

family he has to take an unskilled job as a bus conductor at £5 for a 48 hour week. He told me that even trained male nurses will not be returning to their old profession on those terms. It is exactly the same with the women—I am, etc.

C M BILLINGTON

Judicial Functions

SIR—The case of Dr Hennessy in which disciplinary action by the General Medical Council resulted in his name being removed from the *Register* and its sequel in the High Court when he was awarded exemplary damages against his accuser before the GMC having particular regard to Mr Justice Charles's remarks on the evidence again gives rise to doubts, which have often been expressed before as to the propriety of the GMC in its present form having any judicial functions at all. Quite recently we heard of another doctor whose name this body thought fit to remove from the *Register* apparently because he failed to visit his patients—surely a matter for action by the patients themselves in the ordinary courts of the land or for the panel committee or other contracting body or, possibly even for the police if the alleged negligence amounted to an offence rather than for a professional tribunal in the first instance.

Further it seems possible if not probable that we may anticipate a State Medical Service the Bill for which contains certain disciplinary clauses that appear to provide for other quasi-judicial tribunals with disciplinary powers—see Section 42—who will have what practically amounts to power to take away a professional man's means of livelihood for under such a service as this Bill provides there would be very little left for the average medical man to do to earn his living in a respectable or legitimate way if he wishes to practise outside the scheme.

The GMC is composed of very senior members of the profession, and is certainly not representative of a cross section of the medical public whose members it has powers to try. Of its 40-odd members only 7 are directly elected by the profession as a whole and by vote, the remainder are appointed.

As regards the tribunals with disciplinary powers contemplated under the Bill goodness knows who will compose them except that they will be appointed by the Minister and presumably, if they wish to hold their jobs they will carry out official or unofficial Ministerial policy, and will accordingly be likely to deal suitably with recalcitrant members of the profession. Some of us may have already had experience of this kind of "justice" during our Service careers.

For these and other obvious reasons it cannot be urged too strongly that medical men should unite on this point, if on no other, that they should be afforded the ordinary rights of British citizens where penal measures or questions affecting personal or professional character are concerned, especially where such proceedings may affect a man's means of livelihood. It is a cardinal principle of British law that a man should have the right to be tried by his peers and in open court according to the ordinary rules relating to evidence and procedure. This would seem to imply in professional cases a jury of doctors roughly equivalent in status to the accused and taken from a cross-section of the medical public, instead of a kind of "Star Chamber" composed of the medical *elite*, or, worse still, what might eventually turn out to be a panel of "yes men" appointed by an unscrupulous Minister to carry out his designs. In the case of Dr Hennessy the GMC by its action removed his source of legitimate livelihood, and did permanent damage to his reputation which no action they may now take could ever erase, and this apparently on evidence which, judging from the judge's remarks could hardly have constituted proof in a legal sense, to say the very least of it. It would seem unlikely, as things are at present, that the injured doctor would have any legal remedy against the GMC for the damage done.

The solution would be that neither the GMC nor any other body should have the right actually to try anybody at all. This right should be the exclusive prerogative of the Crown acting through the ordinary courts of the land. In any case in which the GMC or any other body wishes to take action against a doctor such action should be taken in the ordinary courts and the accused tried in accordance with Common Law and the established rules of evidence and procedure as practised in the courts. After a court has reached an adverse

verdict, the question of sentence, if the matter is a purely professional one, might be left to the GMC or other disciplinary body. Of course in this case the accused would automatically have right of appeal to a higher court against the sentence of the lower one. What is so objectionable about the present and probable future position is the idea of a selected court, appointed by higher authority and with powers of inflicting what amounts to a "professional death sentence" against which there is practically no method of effective appeal to an impartial and disinterested tribunal.

I have no personal knowledge of Dr Hennessy, and this letter is actuated by a desire to ensure justice for medical men on the same terms as are available to other citizens. After spending the last six years in fighting for so-called democracy and a reasonable degree of freedom, it is felt to be the duty of all right thinking people to protest as forcibly as possible against anything savouring of totalitarian methods—I am, etc.

London W. 1

JOHN C NICHOLSON

Paralysis Agitans: A Disclaimer

SIR—May I state the position of the Parkinson's Research Society? The society was formed by near relations of victims of this terrible disease stated to be incurable, to produce funds for research in the hope of finding a method of cure. We naturally turned to the National Hospital for help. Mr Mitchell their secretary became our secretary, and Dr Carmichael joined our committee. Among the doctors circularized was Dr W M Crofton, who wrote to me as follows: "There is no necessity to do any research in Parkinson's disease. The microbial cause of this is completely worked out and a specific method of treatment can always be used. If this is used when first symptoms appear the case is rapidly cured. Even in seriously damaged cases arrest and improvement in symptoms have been amply demonstrated."

Dr Crofton informed me that this form of Parkinsonism was long ago discovered to be one of the sequelae of influenzal encephalitis for which a method of specific treatment had been discovered as long ago as 1918 and a paper published on it in the *British Medical Journal* of 1919. To sufferers who had been informed that the cause and cure were unknown this was a great hope. I asked Dr Crofton to demonstrate cases to the committee. This he did to the satisfaction of the committee and the great interest of two doctors—one from the Northern Hospital where nearly 20 years ago Dr Hill had satisfied himself by the cure of hitherto incurable sequelae. He published his results. Mr Mitchell and Dr Carmichael excused themselves from attendance at this meeting. The National Hospital now repudiates further connexion with this society and says their medical committee cannot endorse these claims which they have not even tested. But respectfully I would point out that the cured sufferers and those who have benefited by the treatment can endorse the claims, at least in so far as the treatment is concerned. We are not a commercial association for the purpose of selling drugs or enriching ourselves or anybody else—we are "incurable" sufferers seeking a cure by whatever means possible, and this we appear to have found. I cannot see that it is in the public interest for a hospital medical committee to issue a disclaimer which is tantamount to a negative of these claims without any test whatever—I am, etc.

E TELLER.

* * We imagine that the reference to the *British Medical Journal* is to a paper by Dr Crofton on "Cause, Prevention, and Treatment of Influenza," published on March 1, 1919 (p 240)—ED, B M J

The final arrangements have now been made for the Health Congress to be held at Blackpool from June 3 to 7 by the Royal Sanitary Institute. Lord Woolton will be installed as president at the inaugural meeting and on the other four days 38 addresses and papers will be presented. The subjects for discussion include the social pathology of rheumatic fever, the future of the special hospital care of children away from their parents, the future of paediatrics care of the aged in health and sickness, the nutritive value of processed foods, pathology in its relation to meat inspection, the tuberculin test and the control of bovine tuberculosis, hygiene of food premises, housing and slum clearance. In addition to these discussions many visits will be paid to places of public health interest.

Obituary

J. W. W. STEPHENS, M.D., F.R.S.

The death of Prof. J. W. W. Stephens, F.R.S., at his home at Ferryside, Carmarthenshire, on May 17 will be a cause of deep regret to those who during the early days of research in tropical medicine collaborated with him, as well as to many who passed through the Liverpool School of Tropical Medicine during the years he was professor at Liverpool and to those who later knew him as president of the Royal Society of Tropical Medicine and Hygiene—a society in the welfare of which he took a great interest.

John William Watson Stephens was born in 1865 at Ferryside. He was educated at Dulwich College and at Gonville and Caius College, Cambridge, and studied medicine at St. Bartholomew's Hospital. After taking his B.A. and qualifying M.B., B.Ch. in 1893 (followed in 1898 by M.D. and D.P.H. in 1894) he spent a number of years in research, holding the Trevor Lawrence studentship in pathology at Bart's 1895–6 and the John Lucas Walker studentship in pathology at the University of Cambridge in 1897, his work at this time being mainly in bacteriology. In 1898 he was appointed a member of the Malaria Commission of the Royal Society and Colonial Office, and from then until 1902 did pioneer work on malaria and blackwater fever, first in Central and West Africa and later in India. At this time, immediately after Sir Ronald Ross's discovery of the mosquito cycle in malaria, practically nothing was known about endemic malaria, and the foundations of our present knowledge on this subject are largely the result of this early work by the Commission. One of the most important problems facing the Commission was the nature of blackwater fever, and to Stephens, more than any other investigator, has been due the now accepted view that it is a consequence of repeated malaria infection. At the time the Commission concluded its work the Liverpool and London Schools of Tropical Medicine had been founded, and shortly after the opening of the former school Stephens was appointed Walter Myer's lecturer in tropical medicine there, and eventually, on retirement of Sir Ronald Ross, to the Alfred Jones Professorship of Tropical Medicine, Liverpool University, an appointment which he held from 1913 to 1928 and during which he contributed greatly to knowledge of tropical medicine. It was Stephens and Fantham who first distinguished and named the important trypanosome *T. rhodesiense*. It was Stephens again who distinguished and named *Plasmodium ovale*, the only malarial parasite other than the three classical species that has been fully established.

During the 1914–18 war Stephens, at the head of a team of research workers, carried out important researches on the treatment of malaria by quinine which largely altered the then existing ideas of methods of administration and were largely the reason for modern views on this subject. At this time, with the rank of lieutenant-col., R.A.M.C., he was consultant in malaria, Scottish, Northern, and Western Commands. For his work he received the Charles Kingsley Medal in 1918, was Membre d'Honneur de la Société Belge de Médecine Tropicale, 1923, was Mary Kingsley Medallist, 1929, Manson Medallist, 1935, and Membre d'Honneur de la Société de Pathologie Exotique, 1936. He was president of the Royal Society of Tropical Medicine and Hygiene, 1927–9, and on his retirement from the professorship at Liverpool was made emeritus professor by the School.

As an investigator Stephens was one of the most critical and exact of any known to the writer in his long experience, and at the same time tireless in arriving at the basic truth in any subject he took up. His differentiation of *T. rhodesiense* and of *P. ovale* from classical examples of critical scientific acumen. As a man Stephens was rather reserved, utterly straight and absolutely incapable of anything but large-minded appreciation of others and their work. He has been the writer's greatest friend since the times spent in the towns and jungles of Africa and India. His chief recreation has been observation of bird life, and latterly, since his retirement, local archaeology, to which he contributed scientifically in one or two papers.

S. R. C.

Dr. W. F. L. DAY died on April 27 at Truro in his 69th year. He had retired, on account of ill-health, from his work as county tuberculosis officer for Cornwall, at the age of 67, during

the last war. He was the youngest son of the late Dr. R. N. Day of Harlow, Essex, and a grandson of Dr. F. N. Day of Chudleigh in Devonshire. Mrs. W. F. L. Day is a daughter of the late Dr. Williams, M.O.H. for Plymouth. These medical associations emphasize and may partly explain his love of his profession, which was very obvious to his patients and his medical colleagues. He was educated at Cheltenham and Caius College, Cambridge. He was a very prominent member of the Cheltenham cricket team and narrowly missed a Blue at Cambridge; later in his life he played for Cornwall on various occasions. In the 1914–18 war he was a member of the R.A.M.C., and when demobilized in 1919 began his duties as assistant county tuberculosis officer at Truro. He took a keen interest in the work of Epsom College and sent both his sons to that school. His elder son, Dr. F. M. Day, is now acting as M.O.H. for the Metropolitan Borough of Hammersmith. Immediately after his death the Cornwall Public Health Committee passed a vote of sympathy with Mrs. Day and family, and the chairman stated that the committee appreciated to the full the valuable work which had been done by Dr. Day as tuberculosis officer, and said that no man could have been more faithful to his work.

The death of Dr. WILLIAM HARRIS BEST occurred at St. Ives, Cornwall, on May 8. He was born at St. Ives in April, 1866, educated at Louth Grammar School, and received his medical training at the London Hospital Medical School, for which he consistently maintained throughout his long life a profound affection. For many years he was engaged in a large general practice in Ilford, and was one of the early founders of the general hospital there before his removal to Bournemouth, when he obtained the M.R.C.P. diploma and practised for many years as a consulting physician. Dr. Best was a former president of the Bournemouth Medical Society; he served in the 1914–18 war, and his skill as a neurologist was well demonstrated on the medical board of the Ministry of Pensions at Southampton during 1920–30 and in the early years of the recent war as consulting physician at the Fairmile E.M.S. Hospital. He excelled in dissecting and unravelling difficult diagnostic problems, and was a very successful, highly esteemed, and conscientious colleague who never spared himself in service and in the acquisition of modern scientific knowledge and developments. His colleagues and patients will gratefully remember withal his sterling high character and his courteous, kindly, and strictly ethical integrity. Dr. Best leaves a widow and two sons to mourn their loss.—W. A.

We regret to announce the death at the early age of 41 of Dr. ARTHUR SEWELL WESSON, physician in charge of the department of physical therapy at University College Hospital and at the Royal Surrey County Hospital, Guildford. He studied medicine at U.C.H., qualified in 1925, and took the M.B., B.S.Lond. in 1926, and the M.D. in 1928. He became a Fellow of the Royal College of Surgeons of England in 1936 and was elected a Fellow of the Royal College of Physicians in 1944. Dr. Wesson's early appointments at U.C.H. were those of house-physician, house-surgeon, and resident medical officer, and he won the Bilton Pollard Fellowship; later he was pathologist at the Queen's Hospital, Birmingham, and deputy medical superintendent of Mile End Hospital. He published a number of papers on rheumatic disorders. During the recent war he served in the R.A.M.C., reaching the rank of lieutenant-colonel; he was released in October, 1945, and mentioned in dispatches. Dr. H. V. Deakin, lately physician to the Falmouth Hospital, sends a personal tribute from which we quote the following extracts: It must be about nineteen years ago when I received an urgent message to take a sick parent to the South of France. U.C.H. came to the rescue, and I received a telephone message to say that a first-class man was being sent down to be my locum. After a very full twenty-four hours with Arthur Wesson I left Falmouth with a light heart and did not return for five weeks. He had endeared himself to everyone; children adored him. His greatest gift was the happiness and joy he brought to others of all ages and in all walks of life. He had all the gifts that go to make that patient-doctor relationship such a firm and happy bond in general practice: a kindly nature, endowed with human sympathy and understanding, together with a delightful charm of manner and a very keen sense of humour. He came down and did several other locums, and "little Wesson," as he was affectionately termed in Falmouth, was well remembered there up to the time I left. After my retirement from practice I returned to London and started to look up old friends this year. I was distressed to hear that he was seriously ill, and then a few lines arrived asking me to call and see him in the private wing of U.C.H. Although so frail in body that same cheerful spirit would not be daunted, and we had several happy talks about old times.

Universities and Colleges

UNIVERSITY OF LONDON

The following candidates have been approved at the examination indicated:

THIRD M.B., B.S.—J. B. Walter (with honours and distinguished in pathology), Patience C. Agate, F. Alberts, P. Alwyn-Smith, J. L. Anderson, R. P. Aronson, W. W. Bardiger, A. G. Beaman, D. L. Bennett, P. Blackledge, A. R. Blowers, K. W. Bolt, D. F. V. Brundson, Barbara Burdett, C. B. Burdett-Smith, Olive N. Bywaters, G. B. Chamberlain, D. J. Charles, J. F. Cleobury, M. W. Clough-Ormonston, P. Coling, H. R. Colquhoun, Phyllis M. E. Cook, L. Cudkovic, H. D. Dale, Vera M. Dalley, P. W. Darby, H. J. P. Davies, D. A. Dawson, D. J. Dennison, Phyllis M. De Saram, A. L. de Silva, J. R. Dickson, A. J. Dinn, A. E. Doyle, G. Dutton, J. H. O. Earle, D. R. Edwards, T. H. Elias, W. E. D. Evans, Mary E. G. Feetham, T. R. L. Finnegan, Elspeth M. Frith, O. Garrard, H. S. Gavounis, J. S. L. Gilman, Norah E. Gilchrist, A. A. Glynn, Marjorie Colombi, J. S. Gornill, R. H. Gornill, R. V. H. Goulder, D. S. M. Graham, L. M. Green, D. L. Griffiths, D. D. ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a special meeting of the Royal College of Physicians of London held on May 16, with the President, Lord Moran, in the chair, the following resolutions on the National Health Service Bill were passed:

1. The College acknowledges the urgent necessity for reorganization of the hospital service and approves the principles of the relevant proposals in the National Health Service Bill.
2. Much will depend on the Regional Boards, and the College agrees that the appointment of their members should be determined entirely by their personal fitness for the work.
3. To foster local interest and to encourage initiative the College believes that it is essential to allow hospitals as much independence in administration as is compatible with the regional plan, and for the same reasons it considers that in the case of endowments due account should be taken of the wishes of the donors.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Gift from Australia

The letter printed below enclosing a gift of £1,000 has been received by the President of the Royal College of Surgeons of England, Sir Alfred Webb-Johnson, from the President of the Royal Australasian College of Surgeons, Mr. H. R. G. Poate. This gift is in addition to a donation from the Fellows of the Royal Australasian College resident in New Zealand, and, with the individual contributions of surgeons in the two Dominions, brings the sum given by surgeons in Australia and New Zealand towards the restoration of the Royal College of Surgeons of England to £2,300. This evidence of the loyalty of Fellows of the English College resident at such a distance, and of the attachment of the Fellows of the Australasian College, will be a great encouragement and inspiration to the Council in its efforts to make the Royal College in Lincoln's Inn Fields a still more worthy headquarters of British surgery. Its endeavour will always be to provide full facilities for postgraduate study and research in the scientific departments and the unique museum, which have an imperial value and significance. The letter is dated April 30, 1946, and reads:

Dear Mr. President,

It gives me the very greatest pleasure to forward you the enclosed draft for £1,000 sterling, which represents a gift from members of the Council and Fellows of the Royal Australasian College of Surgeons resident in Australia, towards the cost of rebuilding the Royal College of Surgeons of England. In forwarding this amount, may I say that we all consider it a great privilege to have the opportunity of contributing our mite towards the restoration of the seat of learning to which we owe so much.

We in Australia cannot and never will forget what we owe to the Royal College of Surgeons of England, which has done so much towards raising the standard of surgery throughout the British Empire. I would like also to add that this feeling of Australian surgeons towards the Royal College of Surgeons of England only typifies the feeling which the Australian people generally have for the people of England, who have done so much and suffered so much throughout the present war.

We trust that in the very near future that great seat of learning at Lincoln's Inn Fields will again be restored, and so provide the facilities which we, as members of the British Commonwealth of Nations, have looked to in the years gone by.

At a meeting of the Royal Faculty of Physicians and Surgeons of Glasgow, with Mr. William A. Sewell, President, in the chair, J. D. P. Graham, M.D., was admitted a Fellow of Faculty *qua* Physician.

Medical Notes in Parliament

HEALTH SERVICE BILL

The Standing Committee of the House of Commons resumed on May 15 consideration of the National Health Service Bill, Mr. BOWLES being in the chair. The first day's proceedings were reported in the *Journal* last week (p. 779).

Continuing with Clause 2, which deals with the Central Health Services Council and Standing Advisory Committees, Mr. WILLINK moved to omit the provision that each committee should be set up for the purpose of advising the Minister as well as the Central Council. He wished to be assured that when the Minister received the advice of Standing Advisory Committees that advice would also be made known to the Central Council. It was desirable that the Council should always know what a committee dealing with one particular side of the service was advising the Minister. Mr. BEVAN said he could give Mr. Willink the assurance he wanted. There was no danger of divergent activities. Though in urgent circumstances the Minister might have to act on the advice of a Standing Committee, nevertheless that report would be made known to the Central Council and would form part of the Central Council's annual report. Mr. Willink withdrew his amendment.

WITHHOLDING THE COUNCIL'S REPORT

Mr. MESSER moved an amendment dealing with the provision that the Minister may refrain from laying before Parliament a report, or part of an annual report, from the Central Council if he thought that to do so would be contrary to the public interest. Parliament should know the circumstances of public interest which would make it necessary to refrain from laying such a report. Mr. BEVAN replied that there were few instances in existing legislation where an advisory council had the right, such as this Advisory Council would have, to publish its reports independently of the Minister. At the same time the Minister must be responsible for the report and should be empowered to prevent publication of matters not in the public interest. If the Minister for any unworthy reason—for example, not to cause himself embarrassment—suppressed any part of the report there would be several ways in which these matters could be raised.

Mr. HOPKIN MORRIS said that when a matter came under the Official Secrets Act the Minister was already covered. In the Bill the Minister was given wider powers than in the Official Secrets Act. Sir HUGH LUCAS-TOOTH said that if the report were confidential members of the Council would be precluded from approaching their M.P.s on the subject and the matter could not be raised in the House because no Member could be properly in possession of the information. Mr. BEVAN said he could not accept the amendment because it would overrule the Official Secrets Act. He remarked that where an individual, even a civil servant, took the view that there was a conflict between what he considered the public interest and the obligation he had entered into, he could take the responsibility on himself of making disclosures. The House of Commons had often been made aware of things which individuals thought should be disclosed in the public interest. Sir HENRY MORRIS-JONES felt that the amendment would tie the Minister's hands in certain circumstances.

Dr. CLITHEROW asked whether reports liable to be withheld included reports of medical research. Mr. BEVAN: They might indeed. Dr. CLITHEROW then asked if it was not in the public interest that medical researches should not be disclosed until they had been absolutely covered in every direction. He was thinking of the sulphonamide preparations and those used in gonorrhoea. Owing to the early broadcast of this information the treatment had resulted in making the disease more permanent rather than in cures.

The amendment was negatived.

Mr. RICHARD LAW moved that the Minister should only withhold a report, or part of a report, after consultation with the Central Council. Parliament was setting up a vast compre-

hensive health service which was subject to a number of fundamental defects, and it was important that the Minister should publish the fullest account by the Central Council of how this machine worked. It would give the Central Council a feeling of greater confidence if it knew that the Minister, before exercising the power of suppression, would talk the matter over with the members and get their views. Mr. BEVAN said he could not conceive a more unhappy relationship between a Minister and an important body than the one which would give rise to the situation described by Mr. Law, but if assurances were necessary he was prepared to accept the amendment. The amendment was agreed to.

SERVICES OUTSIDE THE BILL

On the proposal that Clause 2, as amended, stand part of the Bill, Mr. J. S. C. REID pointed out that the definition of the scope of the activities of the Central Council limited that Council to considering questions arising out of the services provided under the Bill. A number of services were not referred to in the Bill—for example, venereal disease—and were provided under other Acts. The Council would be undesirably limited if the words "provided under this Act" remained. Another matter was that an advisory committee should, in the same way as the Central Council, have a power of initiative to advise on a general subject which related to its own branch of medicine. Looking at the text of the Clause he thought this power was by implication excluded. Sir WAVELL WAKEFIELD asked whether the Central Council's annual report might include "a minority report."

Mr. BEVAN replied that if the Central Council wished to include the observations of members who disagreed with the majority it would probably do so. He would make it quite clear that the Standing Committees would have power of initiation. Mr. Reid appeared to suggest that the Central Council ought to advise the Minister on the sort of legislation which he should ask Parliament to pass. Under Clause 1 it was the Minister's duty to promote a health service designed to secure improvement in physical and mental health and the prevention, diagnosis, and treatment of illness. That was comprehensive, and it would be possible for the Council to advise on subjects of that sort. Where it might be limited was in connexion with industrial health services. He hoped such a service would very shortly be included, but to include it and others now would make the scheme administratively indigestible. Parliament ought to see what sort of pattern emerged before embracing an industrial health service. Educational health services would be slowly assimilated by the services under the Bill. One reason why counties and county boroughs were made health authorities was because they were education authorities at the same time, and it was hoped that the school health services would be gradually assimilated. If there was limitation on the powers of the Central Council to advise where departments or authorities were dilatory the Government would remove that limitation, but he doubted whether there was any.

Mr. LINSTED asked whether publication of interim reports of the Central Council would be withheld until the annual report of the Council reached the Minister. Mr. BEVAN replied that the Minister would be free to publish such reports at any time, but there should not be an obligation on him to publish any one.

The clause as amended was approved.

THE APPOINTED DAY

On Clause 3, which deals with hospital and specialist provision, Sir HENRY MORRIS-JONES moved that the appointed day should not be before Jan. 1, 1950. Unless the appointed day was deferred for a reasonable period the Minister would be unable to fulfil his task. Hospital accommodation was promised under this Clause. At present there was a shortage of something like 200,000 beds. A large number of hospitals were antiquated, also their equipment. The shortage of accommodation was likely to continue over the next few years and to be such that the Minister would not be able to provide the services he proposed. Priority was still for housing. In addition the Minister was to provide medical, nursing, and ancillary services on a vast scale—all by Jan. 1, 1948. There was not the medical personnel in this country to run such services. Health centres had to be built or adapted by local authorities. How were these authorities to do this by the appointed day which the Minister had in view?

Mr. BEVAN said that if facilities were bad, as they were in many parts, the sooner they were rationalized and improved the better. It would be disastrous if the National Insurance Scheme came into operation and £30,000,000 were collected from people towards hospital services which the Government was unable to provide. If a long gap occurred before the measure was put into operation the voluntary hospitals would be in a serious financial state. It was already going to be

difficult in the interval for many of them to obtain their normal revenue. The amendment was negatived.

MINISTER'S SOLE RESPONSIBILITY FOR HOSPITALS

Mr. WILLINK moved to alter the proposed duty of the Minister to provide hospital accommodation, etc., and to substitute words ensuring that it would be his duty to "secure the provision by local health authorities or by hospital management committees or boards of governors" of the same services. His amendment dealt with the question whether hospital services were to become the direct responsibility of a Minister of the Crown. The Opposition did not propose any amendment to the earlier subsection of the Bill which gave the Minister power to provide services in accordance with the Act. There was good ground for direct Ministerial responsibility for a national pathological service, but they did not agree that the Minister should be the primary responsible figure for the whole of the hospital services. The Bill made a change of principle which was fraught with great danger. The Minister misconceived the potential capacity of his Department. The amendment was drawn widely so that the bodies responsible for the hospitals might be of various kinds, and the committee was left free to determine in the later stages of the Bill what would be the proper hospital authorities. The real desire was not to change the person who provided the service but to ensure that the service should be planned, organized, and developed with the greatest possible amount of local interest and support.

Mr. BEVAN said that the amendment would completely change the character of the Bill. He agreed that he had overthrown the previous schemes brought forward for hospitals, as they were impracticable and based on a desire to conciliate conflicting interests. Parliament must keep before it the welfare of the patient and not the vested interests of corporate bodies. A great deal of the agitation on this matter was organized by persons who ought to be occupied with their hospital functions. There was no relevance in Mr. Willink's speech unless he had in mind that existing hospital authorities should remain the authorities to provide hospitals. Did Mr. Willink contemplate that voluntary hospital authorities should continue to provide hospitals?

Mr. WILLINK replied that it had never been his idea or that of the Conservative Party that the existing voluntary hospitals should be included in the same lay-out or constitution as they were now. The new authority should be an autonomous but regulated institution fulfilling the same sort of function as a statutory company or a local authority. Certain hospitals should be transferred from minor to major authorities; the smaller counties and county boroughs should cease to be hospital authorities; some voluntary hospitals should cease to be independent self-managing authorities. The vital question was whether they should continue to be autonomous hospitals only controlled by the Minister or whether they should become his servants.

Mr. BEVAN pointed out that Mr. Willink faced the problem of organization not functionally but politically, and sought to reconcile interests instead of organizing the hospital services. If hospital provision was left to autonomous bodies with indirect control there would be no guarantee that they would be able to fulfil their functions, and the only discipline that the Minister could exercise over them would be by withholding a grant. Mr. Willink's principle of indirect control ruptured the implied contract between the Government and the citizen. What the Government scheme did was to impose upon the Minister the duty of providing the service, but it entrusted administration to local members. To whom were voluntary hospitals now responsible? What authority could act on behalf of a complainant? In future there would be the house committee, the management committee, the regional board, and the responsibility of the Minister to Parliament as well as Questions in the House. So far from this service being subject to centralization the administration would be much more human than that which existed in many hospitals now. Mr. Willink's plan would provide, on the one hand, a paper planning authority and, on the other, an executive divorced from it.

Mr. HENRY STRAUSS could not share Mr. Bevan's view that the great hospitals which feared his proposals could be dismissed as mere sectional interests unconcerned with the public interest. He believed those fears were justified. These hospitals were made efficient by a sense of personal responsibility and self-government.

Mr. LIPSON saw objections to the responsibility for actual provision of the hospital services resting with the local authorities. Doctors had a rooted objection to being under control of the local authorities. They preferred the proposals in that Bill to those in the White Paper, very largely because they (the doctors) would not be under the control of the local authority. Dr. STEPHEN TAYLOR agreed with Mr. Lipson. Doctors were

opposed to coming under local authorities because the possibilities of senior appointment were very limited in local authority hospitals. The virtues of voluntary hospitals sprang more from the internal staff arrangements than from their peculiar method of finance. There would be no difficulty under the new arrangements in preserving the voluntary hospital system of staffing. Mr STRUSS's assumption that there was some inherent link between research and the voluntary hospital must be dispelled, an enormous amount of research work had been done in municipal hospitals. Most medical research now was directly financed by the Medical Research Council.

Mr MESSER contended that there was nothing in the machinery of a local government hospital which should make it any different from a voluntary hospital. Lord Moran had testified that municipal hospitals in the sector which he controlled under the E.M.S. were as good as any voluntary hospital. Municipal hospitals had hospital staff committees and all complaints went to them. In the hospitals over which he (Mr MESSER) presided no senior officer had power to discharge a member of the staff. There was no possibility of victimization and no reason for fear. The patients had an opportunity to express their opinions. What was lacking at the present time was a national standard. Mr REID said the centralized system gave a temptation to stick to rules and go slow in introducing new ideas. No Government Department had succeeded in conquering those tendencies and Mr BEVAN would not have greater success.

The amendment was defeated by 29 votes to 13 and the Committee adjourned.

Resuming discussion of Clause 3 on May 16 Mr MESSER moved to insert ambulance services among those to be provided by the Minister at or for the purposes of hospitals. If the local health authority were to be responsible for the ambulance services for hospitals, this would be inefficient and unsatisfactory. Mr KEY said he could give the assurance asked for, "services required at or for the purposes of hospitals" included transport of all kinds. Mrs BRADDOCK said a centrally controlled scheme for transport of patients to hospital would be more satisfactory than that each little local authority should have its own ambulance service. Mr KEY replied that there was need for an ambulance service other than the direct hospital one. The counties and county boroughs were the authorities responsible for providing ambulance services under the Bill. The Government thought it better for the local administrative authority to be responsible rather than the Regional Hospital Board. The amendment was withdrawn.

GENERAL PRACTITIONER SPECIALISTS

Col STODDART-SCOTT moved to insert "consultants" in the subsection which authorized the Minister to provide for the services of specialists at a hospital, a health centre, a clinic, or "if necessary, on medical grounds at the home of the patient." He said certain specialists were not consultants and certain consultants might be said not to be specialists. In some areas general practitioners were called out for consultation to give a second opinion because they had the confidence of their colleagues. They had no specialist qualifications nor would they describe themselves as specialists, but they were consultants. Many specialists who were known as specialist surgeons or physicians preferred to be called consultants rather than specialists. All these people would be required in the future health service.

Mr KEY said there was no definition of specialists in the Bill. Regulations would be made under Clause 62 for deciding the qualifications of the people who were to serve in that capacity. Nothing would be added by putting into Clause 3 the word "consultants." A general practitioner specialist could be included if his qualifications met the requirements set out in the regulation. The Ministry did not wish to bind itself to taking into the specialist service everybody who pleased to call himself a consultant. It might be that in the early stages it would be necessary to use the services of less qualified people whom the Ministry would not wish to include later on. The committee ought not to bind itself to the view that general practitioner specialists were essential for inclusion. In that he believed he would be upheld by the Royal Colleges as well as by opinions expressed in the recent hospital surveys.

Sir HENRY MORRIS JONES said a man might be a specialist in diagnosis but was not a specialist in the accepted sense of that word. Mr WILLINK said one of the vices of English medicine had been a tendency to narrow the specialists and a great decline in the number of people of first rate diagnostic capacity who practised the art of general consultant physician. Mr J. S. C. REID asked if the Government proposed to draw the regulations in such a way that one medical man could at the same time be a part-time specialist or consultant and have status under the scheme of a general practitioner. Dr. MORGAN

said there had been an increase in the number of people tending to become specialists within specialism, but there had been no decline in Great Britain of those physicians, some of whom preferred to be known as specialists and others as consultants, who were general practitioners of high standing with great knowledge of general medicine. Dr CLITHEROW said many people who took higher qualifications were definitely in general practice and might be called specialized practitioners. If such a man with consultant's qualifications practised a specialty the committee should look upon him as a specialist. The amendment was negatived.

OPTICIANS

Dr CLITHEROW moved to insert after the word "specialists" the additional category "ophthalmologists and optical practitioners, either full time or part time." During the Second Reading he had asked what was meant by saying that opticians would have proper professional status. Did Mr KEY mean the optical practitioner with qualifications recognized by the Ophthalmic Benefits Approved Committee? Were ophthalmologists and optical practitioners part of the specialist service? Mr KEY said that in this subsection the term specialist meant specialized medical practitioner and did not include anyone who was not a doctor. Therefore it included the ophthalmologist but the optical practitioner came under the category

medical nursing and other services required at or for the purposes of hospitals. Replying to Dr MORGAN, Mr KEY said there was no doubt that the meaning of specialist under Clause 3 was a registered medical practitioner under the Medical Acts who specialized in a particular subject. Mr BEVAN intended that those at present qualified under National Health Insurance would be regarded as qualified for the hospital services which were being developed under the present scheme. He could not pledge the Ministry to say that these qualifications would not be changed as the hospital scheme developed. It might be possible to raise the standard of the people employed. It would not be lowered. Dr. Clitherow withdrew his amendment.

Mr MESSER moved to omit the words "on medical grounds" from the provision that the Minister may provide the services of specialists "if necessary on medical grounds at the home of the patient." Mr KEY said the intention of the words was to ensure that if a specialist was called to a patient's home he went there because there was a need for him and not because of some whim on the part of the patient. If the patient's own doctor said it was necessary for the specialist to come to the home then the specialist went on medical grounds and could only be called there on those grounds. Mr WILLINK said the drafting should be looked at again to make it clear to people that whether they had a second opinion or not depended on the general practitioner. The amendment was defeated by 23 to 17.

REGIONAL PLANNING

Mr WILLINK moved to insert a proviso that "in considering the accommodation and services required as aforesaid the Minister shall have regard to plans prepared and recommended by each Regional Board for its respective area and to the advice thereon of the Central Council." Mr Willink said that in the Bill the functions of the Regional Boards were administrative and not concerned with planning. The Minister should be instructed by Parliament to have regard to plans prepared and recommended by Regional Boards, he should not be the sole person to decide whether the plans were appropriate. On many questions concerning the regional plans the advice of the Central Council should be taken. Mr KEY pointed out that the hospital service was to be a growing service and not circumscribed by a paper plan. Development schemes would result from discussions between the Regional Boards, the Minister, and the Boards of Governors of the teaching hospitals. These would not be included in some formal document. The Ministry wished to avoid an unnecessary number of schemes on paper. Detailed business was not the duty of the Central Council. The Government asked it for advice on special things, not for interference in the development of the service.

Mr BEVAN said the Ministry wished to get its plans into operation quickly so that the service could start on the agreed date. To set up 16 or 20 Regional Boards would take time, and the Ministry of Health would have to hold off until 16 or 20 plans had been conceived in the Regional Boards. These plans would then go to the Central Council, which was an inappropriate body, being largely specialist and medical. That seemed to him the wrong way of setting about the task, because the Government wished to see some common features in all the regions from the beginning—for example, the 1,000-bedded hospital under its management committee. The Ministry wanted consultations with the Regional Boards as they were preparing their plans so that the Minister could accept those plans and put them into operation right away. The first thing he pro-

posed to do immediately Parliament gave him authority was to have the Regional Boards appointed, and the second was to ask those boards at once to prepare draft plans.

The amendment was withdrawn.

Mr. WILLINK moved an amendment to make an inquiry into the subsection of Clause 3 which provided for regulations being made by the Minister "in respect of the supply, as part of the hospital and specialist services, of any medical appliance." Mr. BEVAN replied that by the use of the word "medical" the Ministry was not trying to limit anything. It was dealing with medicine. It was not intended to place any limitation upon the provision of appliances necessary to repair any physical defects or to amplify any physical faculty. He was prepared to accept the amendment.

The committee agreed to the amendment and to a consequential one removing the word "medical" a little later.

In the provision that regulations may provide for payment by the Minister of travelling expenses incurred by a patient availing himself of hospital and specialist services, Mr. WILLINK moved to provide for payment of expenses which needed to be incurred in the future. Mr. BEVAN said it was not necessary to alter the wording to make it clear that expenses where necessary could be paid before they were incurred. But he was prepared to accept the amendment, and it was agreed to.

DEFINITION OF A SPECIALIST

Later, Mr. BEVAN said the service which Parliament had decided to provide was the service which the medical profession declared to be necessary. He must accept examinations and people must pass the examinations before the State could give that kind of service. He could not promise that a State service would be able to give any of those forms of treatment which were being given by general practitioners not qualified in the normal way. He could not say whether homœopathic institutions would be in or out. If they were brought in it would be to provide their own particular form of treatment. The committee might leave them outside when it came to other parts of the Bill and discussed in what ways hospitals would be brought in. The test would be an empirical one of the requirements of the hospital services in a given area. He (Mr. Bevan) conceded it to be vital that the general practitioner should be encouraged to visit his patients in hospital. This business of taking a patient away from the general practitioner, handing him over to the hospital, and then back from the hospital to the general practitioner was wholly bad. The Government wished to encourage the general practitioner to identify himself more with the hospital service and to visit his patients. Many voluntary hospitals stopped the general practitioner from doing this. But it was another matter when the general practitioner claimed to be a specialist. He could not say in the Bill that such a general practitioner should be treated as a specialist, nor that because a general practitioner had one or two successes with a particular ailment he could thereby call himself a specialist. The medical profession had laid down no definition, but he was going to put that duty upon them because some definition was necessary. Clause 62 required him to make provision with respect to the qualifications, remuneration, and conditions of service of any officers employed by any body constituted under this Bill.

Mr. SOMERVILLE HASTINGS asked whether the definition of a specialist would be changeable. In the early stages certain general practitioners might have to be brought in as specialists.

BEVAN said he proposed to ask the appropriate body—the Central Advisory Medical Committee first, because the Central Council would not be established for some time and he would have to act hurriedly—what body they considered ought to advise him for the purposes of this scheme. Definitions must always be regarded as liable to alteration as the service grew. In the meantime, many general practitioners who had shown by qualification and experience that they could be described as specialists could be used for that purpose until the specialist service had been properly established.

Mr. WILLINK asked whether the Minister would also consult knowledgeable people on whether "consultants" would not be a more appropriate word than "specialists." Sir H. MORRIS-JONES asked whether the Minister made any difference between consultant and specialist. Mr. BEVAN replied that if the Ministry was going to pay, as it probably would have to pay, a higher sum for consultants they wanted a genuine second opinion and not a second opinion on the same level. Therefore it was necessary to have some objective definition of what was a consultant; whether the word used was specialist or consultant did not seem to matter. He would have thought that dental services were an essential part of the equipment of the hospitals. Unfortunately, dentists were very short and the Ministry would have to take emergency steps to train them.

Clause 3 as amended was then ordered to stand part of the Bill and the committee adjourned.

Ophthalmic Hospitals Amalgamation

In the House of Lords on May 8 the Royal London Ophthalmic Hospital, Royal Westminster Ophthalmic Hospital, and Central London Ophthalmic Hospital (Amalgamation, etc.) Bill was read a first time. In the House of Commons on the same day a report was received from the Standing Orders Committee that the Standing Orders ought to be dispensed with and that the parties should be permitted to proceed with this Bill.

Distribution of Penicillin

Answering Dr. Clitherow on May 9, Mr. WILLIAM LEONARD said the Ministry of Supply had not completed its arrangements for the distribution of penicillin. Discussions with the Pharmaceutical Society were taking place. No control order had so far been made.

Blood Transfusion: Inadequate Supplies

Sir WAVELL WAKEFIELD inquired on May 9 whether the Minister of Health was satisfied that he had adequate supplies of blood for transfusion purposes, or what steps he was taking to ensure that a sufficient number of donors were available. Mr. BEVAN said the Emergency Blood Transfusion Service had difficulty in recent months in obtaining adequate supplies of blood. He had arranged for a film on this subject to be shown in cinemas and for local campaigns during the summer months throughout the country to encourage people to give blood. The need was as urgent now as it was in wartime. He hoped those who had helped would continue to do so, and that new helpers would enrol when an appeal was made in their locality.

Maternity Accommodation in Greater London.—Mr. ERNEST DAVIES on May 9 asked the Minister of Health to provide additional accommodation for maternity cases in the Greater London area, including Middlesex, in view of the suspension of the L.C.C. evacuation scheme. Mr. BEVAN replied that the scheme mentioned was still operating, though it was not able to meet all the demands made on it. Additional maternity accommodation was being provided in Greater London where the building stringency permitted and the necessary midwives and domestics could be found. More beds were already available than could be staffed.

Chiropody as Health Service.—Answering Mr. Moody on May 9, Mr. BEVAN stated that the National Health Service would provide treatment for foot complaints as for other disabilities. There would be a place for chiropodists in the new arrangements. Details would be settled in the process of bringing the service into operation.

Medical News

A general meeting of the Medical Society for the Study of Venereal Diseases will be held to-day (Saturday, May 25) at 11, Chandos Street, W., at 2.30 p.m., when papers will be read by Dr. Robert Lees and Dr. D. J. Campbell on "Venereal Diseases Overseas."

A joint meeting of the Colour Group and the Medical Group of the Royal Photographic Society will be held at the Gaumont British Film Theatre, 142, Wardour Street, W.1, on Tuesday, May 28, at 6 p.m., at which eight Disney Health Education Films will be shown. These films were made under the auspices of the Office of Inter-American Affairs to teach the elements of health to primitive peoples.

A members' meeting of the Eugenics Society will be held at the rooms of the Royal Society (Burlington House, Piccadilly, W.) on Tuesday, May 28, at 4.45 p.m., for a discussion on "Eugenically Desirable Types." The annual general meeting of the society will be held at 4 p.m. the same day.

After the annual general meeting of the Nutrition Panel of the Society of Chemical Industry on Wednesday, May 29, in the rooms of the Chemical Society, Burlington House, W., a scientific meeting will be held at 6.45 p.m., when papers on the nutritive value (a) of vinegar, pickles, and condiments, (b) of margarine and edible fats, (c) of nuts, (d) of meat extracts will be read and discussed.

A meeting of the Overseas Association of the Medical Women's Federation will be held at B.M.A. House, Tavistock Square, W.C., on Thursday, May 30, at 2.30 p.m. Tea will be served after the meeting.

Circumstances have made it necessary to alter the arrangements for the annual dinner of the Ophthalmological Society of the United Kingdom on May 30. Instead of as announced, on the programme, the dinner will be held at 7.30 p.m. at the Royal College of Surgeons, Lincoln's Inn Fields, W.C.

A clinical meeting of the London Association of the Medical Women's Federation will be held at the South London Hospital, Clapham Common, S.W.4, on Saturday, June 1, at 2.30 p.m., when cases will be shewn by the staff of the hospital.

The Chemical Society and the University of Oxford Alembic Club have arranged a joint meeting to discuss the chemistry of anti-bacterial substances. It will be held at the Physical Chemistry Laboratory, South Parks Road, Oxford, on Thursday, June 6, at 2 p.m., when papers will be contributed by Sir Robert Robinson FRS, Mr J. M. G. Pryce and Prof. C. N. Hinshelwood, FRS, Dr D. D. Woods and Dr E. B. Chain. Fellows of the Society wishing to attend should write at once to Mr F. M. Brewer, Inorganic Chemistry Laboratory, South Parks Road, Oxford.

The Medical Society of the L.C.C. Service will hold two general meetings in June. The first, on Thursday, June 6, will be in the form of a visit to the Roffey Park Rehabilitation Centre in Sussex, when members will make a tour of the centre. The other meeting of the Society will be held at the County Hall S.E. on Wednesday, June 26, at 4.30 p.m., when a discussion on 'Dental Disease in its Relation to Ill Health' will be opened by Mr Ritchie Young.

The annual meeting of the Royal Medical Benevolent Fund will be held at 5 p.m. on Wednesday, June 12, at the Medical Society of London, 11, Chandos Street, Cavendish Square W., when the financial statement for 1945 will be presented and the officers, committee and honorary auditors will be elected for the current year.

The Scottish Council for Health Education announces three residential summer schools on the general theme of 'healthy living' to be held at St Andrews and Edinburgh this summer. Particulars from the secretary, 3, Castle Street, Edinburgh, 2.

Dr J. A. L. Vaughan Jones, honorary secretary of the Leeds Division of the B.M.A., and joint honorary secretary of the Joint Council for Industrial Medicine, has been appointed a Justice of the Peace for Leeds.

Dr E. B. Chain, a leading member of the team of scientists working at Oxford on penicillin, is leaving for Paris on May 28 to lecture on penicillin in the series by eminent British scientists arranged with the help of the British Council at the Palais de la Découverte. He will also lecture on 'The Chemistry of Penicillin' to the French Biochemical Society.

A one-day conference to discuss problems connected with industrial information services was convened by the Association of Special Libraries and Information Bureaux and held in Manchester on May 8. About 100 members and guests attended. It is hoped that a printed record of the proceedings will be available in due course from Aslib, 52, Bloomsbury Street, London W.C.1.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In England and Wales there was a sharp rise in the incidence of whooping-cough, notifications being 478 in excess of the preceding week's total. A rise was reported for dysentery 49, and falls for scarlet fever 109 and measles 82.

The largest increases in whooping-cough were those of Yorkshire West Riding 70, Middlesex 67, Staffordshire 54, Surrey 46, London 42, Lancashire 42. A small decline in measles was recorded in most areas, notably Essex 35, and the only marked exception to the general trend was a rise of 71 in Lancashire. The decrease in scarlet fever was largely contributed by London and Lancashire, where the cases were 39 and 36 fewer than in the preceding week. The largest variations in the incidence of diphtheria were an increase in Warwickshire 14 and a decrease in Lancashire 28.

The principal returns of dysentery were those of London 31, Lancashire 28, Surrey 25, Middlesex 19, Lincolnshire 12, Gloucestershire 10.

In Scotland a very large increase occurred in the incidence of measles, from 354 to 1,059. Rises were also recorded for whooping-cough 61 and scarlet fever 14. Notifications of diphtheria declined by 13. The totals for dysentery have been almost constant during the past three weeks, varying only between 60 and 63.

In Eire the notifications of measles increased by 20 and the cases of diphtheria declined by 8. The incidence of diarrhoea and enteritis remained unchanged at 42.

In Northern Ireland the cases of scarlet fever were 13 and whooping cough 18 above the total for the preceding week.

Infantile Paralysis in Australia

The outbreak of infantile paralysis in New South Wales continues to spread. 357 cases have been reported this year.

Week Ending May 11

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,022, whooping-cough 2,180, diphtheria 368, measles 2,570, acute pneumonia 445, cerebrospinal fever 61, dysentery 137, paratyphoid 1, typhoid 9, smallpox 2.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 4.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under the Infectious Diseases Act, for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases, a blank space denotes disease not notifiable or no return available.

ANY QUESTIONS?

Remedies for Herpes Zoster

Q.—*I am told that contramine has been found specific for herpes, the first injection relieving pain. Can you give me further details?*

A.—Contramine, which is diethyl-ammonium diethyl-dithiocarbamate, has been used for many infections, toxæmias, and states of shock. I am unfamiliar with its use in herpes and could not find a reference to it in the indexes covering the last few years. I presume the question refers to herpes zoster and not to herpes febrilis. Many remedies have been prescribed, but none has stood the test of time. The fact is that the clinical course of herpes zoster is so variable that one may easily obtain a short series of apparently highly successful responses to any form of therapy, but the broader test is likely to be disappointing. Some believe that daily injections of 0.5 ml. of pituitrin are successful in relieving pain and promote a rapid and satisfactory resolution. Intravenous injections of 10 ml. of 20% sodium iodide have also been recommended, and, more recently, injections of whole blood beneath the area of the eruption and about the corresponding posterior root ganglion have been said to be quickly effective. To the critical observer it is evident that there is no specific remedy yet for zoster or for herpes febrilis. Since both diseases are undoubtedly due to viruses, a specific would have to be a lethal or inhibiting agent for these infections, and contramine or, indeed, any of the remedies mentioned have no claims to be such agents.

Chronic Facial Spasm

Q.—*A woman of 58 has intolerable discomfort from blepharospasm, risus sardonius, and choking feelings. Phenobarbitone has little, if any, effect. What is the treatment?*

A.—The aetiology of spasms such as those described is uncertain. The commonest variety is a spasm confined to the orbicularis oculi, synchronous on the two sides. The closure of the eyes is much more prolonged than in the common blinking tic of childhood, and the spasm may be practically continuous. The disorder is seen particularly in elderly women. Rarely, as in the case reported, other muscles of the face and those of the tongue and pharynx are also involved. The condition is sometimes regarded as a neurosis, but the writer's belief is that it is organic in origin. In the absence of post-mortem examination, however, the matter cannot be settled, and there is no clue to the site of the lesion if it is organic. Psychological treatment is usually quite ineffective and physical treatment is not much more helpful. Other barbiturates should be tried and will usually produce some diminution in the severity of the spasm.

Testicular Functional Levels

Q.—*Does an undescended testis atrophy after puberty? Does this apply to one in the inguinal canal and/or to one that is outside the external ring but not in the scrotum? Would the function of the testis be normal outside the abdominal cavity but not in the scrotum, or at which site could the organ function normally?*

A.—Abnormality of the undescended testicle may be histologically evident as early as 3 years of age (Cooper), but it is usually only after puberty that any difference can be observed between undescended and normal testicles (Wangensteen).

After puberty the scrotal testicle develops rapidly, whereas the undescended one does not. Moreover, atrophy and degeneration of the tubules occur progressively as age advances (Vines; Pace and Cabot). The further from the scrotum the testicle lies, the more likely is degeneration to appear (Cooper). It is likely at any level, but Cooper quotes the case of a man of 60 whose testicle, situated at the external ring, showed some spermatogenesis. It is commonly believed that only the germinal tissue is affected. This is usually true, but signs of androgenic deficiency are not very uncommon in cryptorchids. The whole subject has recently been admirably reviewed by Bishop.

Pethidine in Midwifery

Q.—*How should pethidine hydrochloride be used in midwifery? Is it justifiable to give, say, potassium bromide and chloral early in the first stage and then pethidine later?*

A.—The drug now known as pethidine in this country was introduced in Germany in 1939, under the name "dolantin," as a synthetic substitute for morphine. In the United States and Canada it is "demerol." Pethidine has now been extensively tried for analgesia in labour. Its chief advantage lies in the almost complete absence of toxicity to mother or foetus even with large doses. Doses of up to 650 mg. have been given in labour with no demonstrable ill effect, except that some patients have complained of slight giddiness or light-headedness. In labour pethidine exerts a satisfactory analgesic effect in a higher proportion of cases, though there is some individual variation in different mothers. There is no amnesic effect unless it is combined with scopolamine.

It is often unnecessary to give pethidine in the very early stages of labour, but there is no reason why it should not be injected as soon as the pains become distressing. An initial dose of 100 mg. may be given intramuscularly, and this may be usefully supplemented with 2 dr. (7 ml.) of syrup of chloral (22 gr., or 14 g., of chloral hydrate) by mouth twenty minutes later. The pethidine may be repeated as often as is necessary to maintain analgesia, even within one hour. If amnesia is required scopolamine should be given as well, but this is not free from danger—owing to a possible effect on the foetus.

Satisfactory results have been claimed from combining pethidine with other analgesics and sedatives, such as heroin, paraldehyde, and the barbiturates. Pethidine alone, or combined with chloral, is often sufficient for the conduct of normal labour, though in many cases, and especially in primigravidae, the analgesia is insufficient for the latter part of the first stage and for the second stage. Here gas-and-air or some other inhalational anaesthesia may be needed.

D.D.T. for Scabies

Q.—*Can D.D.T. be used to treat scabies?*

A.—D.D.T. is not recommended for treating scabies. This substance is an efficient insecticide and has given remarkable results against mosquitoes, flies, lice, bugs, etc. It is much less effective against arachnids (i.e., ticks, mites, etc.). Although the itch mite can be killed with D.D.T., several applications of any such preparation are required to cure scabies, whereas much quicker results can easily be obtained with other preparations (e.g., benzyl benzoate). Finally, it must be remembered that D.D.T. can be toxic to man, and that though when properly used as an insecticide it is not dangerous, rubbing it into the skin (particularly in an oily solution) may easily give trouble.

Amidopyrine and Agranulocytosis

Q.—*Can certain commonly used drugs containing small doses of amidopyrine cause agranulocytosis? If so, why is the use of such drugs not discouraged?*

A.—Agranulocytosis is relatively rare, and it is therefore understandable that there is little opportunity to study its relation to the dose of the substance which causes it. Thus we do not know if a patient who has been taking 0.6 g. amidopyrine (10 gr.) daily and has developed agranulocytosis would also

have developed it had he taken only 0.12 g. (2 gr.) daily. Recent observations on agranulocytosis after thiouracil have shown that the percentage of patients who develop agranulocytosis when taking a small dose daily is just as high as the percentage of those who develop it when taking a large dose. This suggests that the size of the dose is not the important thing, and that a susceptible person will develop it when taking even a small dose. Little more can be said.

In reply to the second part of the question there is no body in this country which is entrusted with the duty of encouraging or discouraging the use of drugs. Textbooks of pharmacology are available to all, and the medical man generally prefers to form his own opinion after reading them.

Chronic Pancreatitis

Q.—What are the characteristic changes in chronic pancreatitis (1) in the pancreatic juice, (2) in the x-ray appearances of the stomach and duodenum?

A.—The change in the pancreatic juice is a diminution in the active enzymes, particularly in the fat-splitting enzymes. As regards changes in the x-ray appearances of the stomach and duodenum, I should myself place no faith in these, apart from the possibility that deformity might be produced by the increase in size of the pancreas. Radiologists take a different view but I remain sceptical.

Peanut Butter Vitamins and Calories

Q.—What are the vitamin content and calorific value of peanut butter and of arachis oil?

A.—Peanut butter is presumably made by the maceration of the roasted nuts, which are also known as arachis nuts, earth nuts, ground nuts, or monkey nuts. Recent food tables authorized by the Medical Research Council give the vitamin B₁ content of the roasted nuts as 240 microgrammes per 100 g., which may be compared with 363 µg. for Manitoba wholemeal flour. According to Rose, vitamins of the B₂ complex are present, but no adequate analysis has come to our notice. Vitamins C and D are absent. The presence of vitamin A has been reported by some workers, but at the most there can only be traces of carotene associated with the non-oily fraction of the nuts. The roasted nuts contain 49% of oil, and have the high calorific value of 5.84 cal. per g.

Arachis oil, expressed from fresh nuts, is devoid of vitamins A and D, and is, indeed, often used in nutritional experiments as a constituent for basal diets free from the former vitamin. Vitamin E, however, is present in amounts up to 0.13 mg. per g., which is about one-tenth of the concentration in wheat-germ oil. The oil also contains linoleic acid and other highly unsaturated acids, which according to one group of workers make up nearly 25% of the oil. Although the necessity for these "essential fatty acids" as dietary ingredients has been clearly demonstrated in experimental animals, we are still awaiting, as also in the case of vitamin E, adequate proof of their importance for the human being. Arachis oil, in common with other fats, has a high calorific value of about 9.0 cal. per g.

Nervous Regulation of Acid-Base Balance

Q.—How is nervous activity affected by disturbances of the acid-base equilibrium? What is the part played by the nervous system in its regulation?

A.—Changes in hydrogen-ion concentration affect the excitability of the nervous system. An increase in acidity reduces excitability, while a decrease enhances excitability. These effects can be demonstrated on isolated nerve; in an experimental animal the reflex time for the knee-jerk can be shown to be increased by an injection of ammonium chloride and decreased by sodium bicarbonate. The convulsive activity of certain drugs is modified also, in the sense stated above, by acid or alkali. Hyperventilation tetany, where a shift towards the alkaline side of neutrality is caused by the "blowing off" of carbon dioxide, is a striking example of tetany associated with various types of alkalosis.

It is suggested that these effects of altered acid-base balance may be caused by changes in the ionic balance, particularly in the proportion of ionized to un-ionized calcium. An increase in the concentration of calcium ions causes a reduction in excitability and vice versa. In alkalosis the ratio of ionized to

un-ionized calcium may diminish without any reduction in the total calcium concentration.

In the body there are three lines of defence against disturbance in the acid-base equilibrium: the buffer reactions of the blood, the regulation of the breathing, and the ability of the kidney to adjust the reaction of the urine. The nervous system is, of course, concerned with the second of these, the respiratory centre being acted upon directly by the blood and receiving impulses from the chemoreceptors of the carotid and aortic bodies. For instance, a disturbance of the acid-base balance towards the acid side is compensated by increased respiratory activity, which reduces the carbon dioxide tension of the blood.

Lipoid Pneumonia

Q.—Does the instillation of oily nasal drops cause lipoid pneumonia? How long does it take for this to happen, and can it be prevented?

A.—Inhalation of animal and mineral oils into the lungs over a prolonged period may cause "lipoid pneumonia" with areas of consolidation, the alveoli being filled with macrophage cells containing oil droplets. Leucocytic infiltration, fibroblastic proliferation, and finally fibrosis occur. Cod-liver oil is the most common cause in infants; liquid paraffin by nasal instillations or even when taken by mouth in adults. Vegetable oils, such as poppy-seed oil, olive oil, etc., appear to be innocuous.

A brief description of lipoid pneumonia together with references to the literature is given in *Recent Advances in Pathology* by Hadfield and Garrod (J. and A. Churchill, 4th edition, 1942). Prolonged nasal instillation of liquid paraffin or other mineral oils—e.g., for longer than a few weeks at a time—should be avoided.

Oestrogens for Prostatic Cancer

Q.—Is dienoestrol recommended for the treatment of carcinoma of the prostate with secondary deposits in most of the bones of the limbs? I started with a daily dose of 0.3 mg. and increased this to 1.8 mg., whereupon the pains in the limbs, which had been diminishing, increased.

A.—The beneficial effects of oestrogens on carcinoma of the prostate are usually more marked on the prostate itself than on the metastases. Secondary deposits in lymphatic glands may disappear, as may those in the lungs. The effect on bony metastases does appear, from radiological evidence, to be a sclerosing one, but actual disappearance of the lesions is of doubtful occurrence. Determination of the requisite dose of oestrogen is assisted by regular estimations of the serum acid phosphatase, and if the response to dienoestrol is not good it might be worth while reverting to stilboestrol and increasing the dose up to 15 mg. daily. It is not likely that the increased dose is responsible for the worsening of the pain. If oestrogens fail to relieve bone and joint pain a course of deep x-ray therapy may do so; it is, in fact, more likely to be successful.

Causes of Pain in the Legs

Q.—A woman of 45 has severe burning pains in the calves, radiating down to the plantar surfaces of the heels. The pain comes on about two hours after rising and is worse as the weather becomes warmer. She is free from pain in the cold winter months. There are no arteriosclerotic changes. Pethidine gives partial relief. Would sympathectomy help?

A.—The problem here is whether the pain is due to a peripheral neuritis or to a vascular affection. Is there any evidence of alcoholism, or of diabetes? If the pain is neuritic in origin physiotherapy and preparations of vitamin B are indicated, coupled with the usual analgesic remedies. If the pain is of vascular origin vasodilator drugs might help—e.g., "doryl" (Merck) 2 tablets twice or thrice daily; "priscor" (Ciba) 1 tablet thrice daily; or "moryl" (Savory and Moore) 1 or 2 tablets three times a day. Buerger's exercises might be worth trying. Sympathectomy certainly comes up for discussion, but it is necessary to prove that some defect of peripheral circulation actually exists. Ekbohm's "asthenia crurum dolorosa" (*Acta med. scand.*, 1945, 118, 197) also comes into the picture as regards the differential diagnosis. It must be remembered that in peripheral vascular disorders local treatment with cold may prove of greater clinical and physiological benefit than measures aimed at increasing the circulation.

INCOME TAX

Car Expenses

B. R.'s demobilization leave expired on April 3, 1946. He bought a car for £575 on March 28 and began work as an assistant in general practice on June 1. What car allowances can he claim? (It is assumed that his agreement requires him to own and use a car at his own expense.)

He can claim an "initial allowance" (at 20%) and "depreciation allowance" (at 25% per annum) for the period from June 1, 1946, to April 5, 1947. Some difficulty may be experienced in determining the amount on which these allowances should be calculated—assuming that the car was used privately before June 1. A reasonable basis would seem to be to take the starting figure at £575 less 20% depreciation for two months—i.e., £575—(2/12 of 1/5 of £575)=£556. The usual running costs, etc., should also be claimed.

Accommodation of Assistant

F. W. inquires what is the position where accommodation (but not board) is provided for an assistant, but not in the principal's residence?

The matter is not entirely free from doubt, but in our view if the principal engages the rooms and is liable to pay the rent for them he can deduct the rent as a professional expense, but the amount is not chargeable to tax as income of the assistant. If, on the other hand, the assistant is liable to pay the rent but the principal pays it for him, the amount would represent income of the assistant.

Pension: Earned Income Relief

P. B. has retired on a pension from a local authority and tax is deducted under the PAYE system. He inquires as to the "earned income relief".

The "personal" allowances are given by the operation of the Code Number, and P. B. will presumably have received a notice giving him particulars of the allowances being effected in that way. The earned income relief applies to all income coming under "PAYE" and is given automatically by the tax deduction tables. Since the relief varies with the amount of the income it could not be given, as "allowances" are given, in specific sums.

LETTERS, NOTES, ETC.

Balanitis

X. Z. writes: As an elderly surgeon, retired from the staff of a teaching hospital, I should like to add a note to the reply to question under this heading in the issue of the *Journal* of April 27 (p. 671). Balanitis causes physical irritation and mental anxiety. It recurs at intervals. Many years ago I had found local applications useless. As your contributor says, "ordinary personal hygiene and keeping the affected area dry are all that is necessary." The problem is how to achieve this. Circumcision would do so, but the following simple measure renders operation unnecessary. The prepuce is retracted and the patient is shown how to wrap some turns of 1 in. (2.5 cm.) gauze around the glans and the retracted prepuce; the end of the gauze is slit with scissors and tied in a bow knot. The area becomes comfortable at once, but sometimes it is not easy to retain the gauze in position, and when the gauze comes adrift friction with the clothes is rather uncomfortable. The bow knot makes reapplication easy. It is convenient for the patient to carry a roll of 1 in. gauze in his pocket. Only sufficient gauze is needed to keep the prepuce retracted and to protect the glans from friction. For the first few days comfort demands that the gauze be reapplied soon after it has slipped, but very soon the intervals between reapplication are lengthened until, in a shorter time than it would have taken a circumcision to heal, it is found that the glans is no longer sensitive to friction with the clothes, the secretion has dried, the prepuce remains retracted, and no further attack occurs.

Dr. Troup of Pretoria

MISS FRIDA TROUP, B.A., and DR. ADRIANUS PUPER write from Box 5783, Johannesburg: We have collaborated to compile a life of Dr. J. MacD. Troup of Pretoria (whose death last year was recorded in your columns) for private circulation. There must be many among his colleagues, and possibly still some of his university contemporaries, with whom we are not in personal contact, who would like to have a copy. We therefore beg your assistance in making this known. The story is told mainly by contemporary letters, and there is an authentic ring to the account of life as a small boy in Scotland, and later at St. Andrews and Cambridge Universities and King's College Hospital. After Dr. Troup migrated to this country his letters to his brother, Sir Edward Troup of the Home Office, form an interesting contemporary record of everyday life and opinion. Through all emerges implicitly the character of

a man of great character and understanding, who deliberately forsook the youthful promise of professional eminence and shunned fame and wealth for the toil of general practice, preferring its reward of friendship above all other, and gaining, despite himself, an unsought renown. His story is by no means unique in his generation, and this perhaps enhances its interest. We are publishing this book, *Physician and Friend*, by subscription, the subscriber being entitled to one copy for every 30s. paid. Any surplus funds there may be after expenses have been met will be divided between the South African Medical Benevolent Fund and King's College Hospital, of which Dr. Troup was a student and a Governor. Those wanting copies are asked to communicate with us as soon as possible.

Nocturnal Erections

MR. GEOFFREY PARKER (London, W.) writes: I have just read the question and answer (May 4, p. 707) on nocturnal erections. Would you suggest to your writer that he have his patients very carefully urethroscopied. Cystoscopy will reveal nothing, but since I wrote a paper on haemospermia (*Proc. roy. Soc. Med.*) just before I went into the Army I have seen three cases, with very similar symptoms. In two of these a small subepithelial cyst was seen in the prestatic urethra, just distal to the verumontanum, and the third man had a very congested verumontanum. All three appear to have been cured by fulguration of the cysts, which had the effect of bursting them, and also of the congested verumontanum. I do not know what the origin of these cysts may be; they might be retention cysts, following chronic inflammation, or may be congenital in origin.

Dr. H. E. COLLIER (Worcester) writes: Help may be given by (a) regular attention to the bowels and (b) avoiding drinking fluids late in the day. If either of the patients be suffering from a urinary excretory defect (whether due to heart or to kidney), the erections and passage of urine at night may be attributable to the defect. The erections may be "caused by" the full bladder.

Nocturnal Proctalgia

Prof. F. C. PYBUS writes: In 1910 I sent a description of this condition—which I called nocturnal rectalgia—to the *B.M.J.*, but which apparently was not thought worthy of publication. It was a most definite reality, for I became acquainted with it while house-surgeon at the Gordon Hospital, S.W. (in 1909). I could find no account of it in the books on surgery or rectal diseases, and it was apparently unknown to any proctologist with whom I was then in contact. As this rectal pain is sometimes accompanied by priapism it might have been thought to be due to a prostatic lesion, but its occurrence in the female proved this incorrect. Indeed it may affect a whole family, male and female alike. In 1931 I had, through a request in the *B.M.J.*, considerable correspondence with doctors who suffered from it or who had met with it in their practices. I am now, however, able to indicate a means of speedy relief. If the sufferer will start the gastro-colic reflex by taking food or drink (preferably the former) he will find that within a few seconds the pain will disappear as if by magic.

Stethoscopes for the Deaf

Dr. C. H. R. KNOWLES, of Sutton Emergency Hospital (Sutton, Surrey), writes: In the answer to a question on the most efficient type of stethoscope for the use of a deaf doctor (April 20, p. 633) no mention is made of electric stethoscopes. A highly efficient instrument of this type has a piezo-electric crystal microphone, with tone and volume controls, and is fitted into a small portable case. My own deafness is such that with the ordinary varieties of stethoscope (and I have tried them all) I can never hear such sounds as crepitations or an aortic diastolic murmur, and very often I am quite unable to hear the heart sounds or the normal respiratory murmur. With the acquisition of one of these electric stethoscopes, however, all my auscultatory problems have been solved; and my deafness is in this respect perfectly compensated. If the querist would care to communicate with me I should be delighted to give him further details of my experience with this instrument.

A Clean Shave

Dr. WILLIAM MURRAY (Birmingham) writes: Dr. L. Erasmus Ellis (May 4, p. 710) mentions that with seven razor blades and using a different one each day of the week, some of them last for months. I think it is worth noting that I have no difficulty in making one razor blade last a year, by the simple expedient of rubbing it gently every day on the inside of a common glass tumbler filled with hot water. I have used only three blades in the past three years, and all were blades that had previously been discarded as finished.

Precaution when Using Throat Packs: Correction

We hasten to correct a misprint in Dr. H. Parry-Price's note published last week (May 18, p. 786). The fifth sentence should read: The lid of the throat pack tin is painted red, and across it in white letters "THROAT PACK IN."

BRITISH MEDICAL JOURNAL

LONDON SATURDAY JUNE 1, 1946

PROGRESS IN THE CONTROL OF LEPROSY IN THE BRITISH EMPIRE*

BY

Major-General Sir LEONARD ROGERS, K.C.S.I., C.I.E.
M.D., F.R.S., F.R.C.P., F.R.C.S.

Late President Medical Board India Office

Before the discovery of improved methods of treating leprosy in 1915-17 little advance in preventive measures had been made since as in Biblical times and in the Middle Ages, compulsory segregation was the only measure in common use. This in practice meant imprisonment—usually for life—such as has never been used in any other chronic disease, but in the case of leprosy it was sanctioned by public opinion on account of the great and usually unjustified dread of the crippling and disfiguring effects seen in advanced cases in the absence of any known effective treatment. Thirty years and less ago compulsory segregation was practically the sole method in use for the control of leprosy in the Dominion of Canada with very few cases in Australia with rather more, and in South Africa with many cases, as well as in the West Indies, British Guiana, Ceylon, Malaya and Fiji. In India it was legalized in all cases showing ulceration but was rarely enforced except in a few large cities. In our tropical African Colonies it was quite impracticable, as it led to every case being hidden.

Failure of Compulsory Segregation

Under favourable European conditions in Norway the provision in 1856 of hospitals or sanatoria for leprosy patients with a minimum of compulsion led to a great reduction of the disease during the next seventy years, but in poor and backward tropical races compulsory segregation has never succeeded in its avowed object of materially reducing the incidence. In Hawaii, French Guiana, and other countries political vagaries handicapped its use. In South Africa the measure was first introduced in 1817 yet the average yearly admissions to the Cape Colony Robbin Island prison-like leper asylum rose steadily from 21 in 1845-52 to 100.7 in 1894-1905. In 1906 American authorities made a characteristically thorough attempt to stamp leprosy out of the Philippine Islands by the compulsory isolation in a newly constructed settlement on remote Culion Island of every case they could discover. In 1930 5,000 cases were segregated, yet the number of yearly admissions remained as high as at first.

Nor is the reason for such repeated failures far to seek, for in South Africa the average duration of the disease when the patients were first tracked down and isolated was six and a half years, and in the Philippines it was eight years. During those long periods other members of their households and close acquaintances had become infected, and they in their turn were successfully hidden for years to infect another series of their relations and neighbours, and so on indefinitely. Truly, even in the early years of the present century the prospects of sufferers from leprosy in the British Empire were gloomy indeed.

Incidence of Leprosy in the British Empire

Another disadvantage of compulsory segregation was that the consequent inevitable hiding of all cases for as long as possible made impracticable even an approximate guess at the magnitude of the leprosy problem in our Empire. In the successive editions of the book on *Leprosy*, by Dr E. Muir and myself I

tabulated all the data for 95 countries of the world that I could discover both in the older literature and in the papers on the subject of the last 24 years during which time I have written extracts of them for the *Tropical Diseases Bulletin*. The following Table shows the known or estimated cases at three periods in India, in British Africa, and other British possessions.

Year	India	Africa	Colonies, etc.	Total
1925	107,513	54,433	3,175	165,121
1930	500,000	502,600	19,422	1,022,022
1946	1,200,000	750,000	50,000	2,000,000

The apparent enormous increase is simply due to the number of early hidden cases found by house-to-house surveys of limited sample areas. Thus, in India, Muir and his Indian assistants found four and a half times as many cases among 2,500,000 persons they examined as had been returned in the same areas at the previous census. A recent estimate has placed the figure at ten times as many, but fortunately only 250,000 of the present total estimate of 1,200,000 are classed as 'highly-infective' cases. Only 14,000 are isolated, about one-third of them uninfected. In Africa about three-fourths of the total estimated cases are in Nigeria. The task of dealing effectively with such numbers is indeed a herculean one. It can never be solved by compulsory segregation of all types of cases as attempted in the past.

Types of Leprosy

There are two very different types of leprosy, which were fully recognized only in the middle of the nineteenth century. The more important is the *nodular*—or *lepromatous*, as it is now called. This is characterized by primary involvement of the skin, in which nodules or thickened patches develop. The forehead face and ears are especially affected, to produce the 'leonine' appearance. The thickened skin contains such enormous numbers of the causative lepra bacilli that they form a considerable proportion of the affected tissues, such as is seen in no other human bacterial disease: they are easily demonstrated by microscopical examination. Both the affected skin and the thickened nasal mucous membrane often ulcerate and discharge myriads of the bacilli, which are frequently sneezed over members of the patient's household or close associates who may thus become infected. These cases run a comparatively rapid course with death usually within eight or ten years of the full development of the disease.

In the *neural* form, on the other hand, the cutaneous tissues show great resistance to invasion by the lepra bacilli, which first involve small superficial nerves, accompanied by patches of discoloured skin with loss of sensation. Lepra bacilli are so scanty that they often cannot be demonstrated in the affected skin, even when that shows some thickening as in the tuberculoid subdivision of the neural types. In more advanced neural cases large nerves of the extremities, especially the ulnar just above the elbow joint, become greatly thickened and damaged by the presence of many lepra bacilli, with the ultimate loss of fingers and toes so familiar in pictures of begging lepers in India and elsewhere. As, however, the bacilli cannot escape from the nerve trunks, neural cases are little if at all

* Abridged version of a paper read before the Dominions and Colonies Section of the Royal Society of Arts. Published by permission of the Society.

infective—a point insufficiently recognized until recently. It is therefore most fortunate that the neural cases are about four times as common as the lepromatous; for this greatly simplifies the problem of the control of the disease.

Recent Progress in Treatment and Control

Having now cleared the ground I turn to the discovery of a method of treatment which enables a large proportion of early cases to be freed from their symptoms; but it is of very little value in the advanced stages seen in nearly all cases in leper asylums. In my Edinburgh University Cameron Prize Lecture in 1929 I showed that no previous treatment had ever cleared up the symptoms of any appreciable proportion of cases. The only remedy that had for long retained a reputation for retarding in slight degree the progress of cases was the ancient Indian chaulmoogra oils, given orally in spite of their nauseating properties. The several varieties of this class of oils consist mainly of fatty acids of peculiar chemical constitution. In 1879 Moss separated the lower-melting-point ones under the name of gynocardic acid; in 1904–7 Wellcome research chemists showed that the main constituents were chaulmoogric and hydnocarpic acids.

Between 1899 and 1910 I carried out occasional trials of treatment and attempted to cultivate the bacillus, but made no progress until I gave gynocardic acid orally, which proved more effective and less nauseating than the whole oil. One medical man I thus treated was cleared of a widespread leprosy rash within a year and showed no active symptoms during the remaining twenty years of his life. In 1912 I endeavoured, unsuccessfully, to obtain a soluble compound of gynocardic acid for trial by injection; but after Dr. Victor Heiser, founder of the Cullion leper settlement, had visited me in Calcutta in 1915 and urged me to take up further work on the treatment of leprosy, I made another effort, and with the help of Dr. C. L. Bose, professor of chemistry, Calcutta, prepared a soluble sodium salt or soap in the form of gynocardate of soda. In 1916 I published preliminary notes on its use by subcutaneous and by intravenous injection. In 1917 I was able to record 26 cases, with a number of convincing colour plates or photos before and after treatment. In cases treated within three years of the onset of symptoms 50% had been cleared up; but only 25% of cases of from three to fifteen years' duration recovered. At the end of four and a half years, out of 51 cases treated for three months or more 41% had cleared up, another 40% had greatly improved, and only one advanced nodular case showed improvement. On the other hand, in very advanced cases, as seen in the Calcutta Leper Asylum, none had cleared up and only slight improvement was seen in some of them. In 1918 my results were confirmed by Dr. E. Muir and others in India; in 1919 Dean and Hollman confirmed them in Hawaii; and they used ethyl chaulmoograte on the same principle with success. A little later Muir, when a whole-time leprosy worker in Calcutta, found that pure hydnocarpus oil could be injected with an antiseptic with good results. The principle I introduced of injecting suitable preparations of these oils, in place of oral administration, has been very generally adopted throughout the civilized world. At the Dichpald Leper Hospital in India, where only fairly early cases were admitted, 90% were cleared of their symptoms; very similar results have been obtained by Dr. Moiser in Southern Rhodesia.

A Dilemma

I was now on the horns of the following dilemma. The improved treatment was of material value only in comparatively early cases of leprosy. The method of control of the disease in general operation was compulsory segregation. Under that system early cases suitable for treatment were all hidden for fear of imprisonment for life. Nothing less than a complete revolution in our two-thousand-year-old conceptions regarding the control of leprosy was therefore required before good use could be made of the improved method of treatment. How was that to be brought about?

Epidemiological Investigations

Early in 1920 I returned to England on sick leave, at the end of which I was superannuated from my life's work in India, just a quarter of a century ago. This enabled me to

spend nearly all of my time during three years, 1921–4, on a comprehensive study of the vast literature on leprosy of the previous 60 years or so, with a view to finding out the conditions under which leprosy cases arose and how to discover and treat them in the early amenable stages of their disease. I thus arrived at certain conclusions, on which I formulated a policy for the gradual control of leprosy wherever it could be carried out efficiently. These conclusions were not altogether new in so far that, as ever in the progress of medicine, they had been pointed out by someone or other with greater insight than his contemporaries. But the facts in question had not then been at all generally accepted; much less had they been acted upon, as the following account will show.

Conditions under which Leprosy is Contracted

The incubation or latent period of several years between infection and the appearance of the first symptoms makes it very difficult to trace the source of infection. An analysis of 700 cases I collected from the literature furnished the following data. In nearly one-fifth infection followed the close contact of conjugal or cohabiting relationship between a diseased and a healthy person. In another two-fifths it was due to living, usually for years, in the same house as a case of leprosy, including 9% sleeping in the same bed with a case. In another fifth infection occurred while in attendance on a leprosy patient—nearly always while living in the same house, for infections of attendants working in well-organized leper asylums with due precautions are very rare. In nearly all of the remaining fifth there was a clear history of close and prolonged association with a leprosy case. In seven of the few remaining cases direct inoculation of the disease had taken place while operating on a leper or through the now obsolete arm-to-arm vaccination in a tropical country. The latter cases are important, as proving that the disease is inoculable; for they support the view, now generally held, that lepra bacilli gain access to the human skin through abrasions or insect-bites during close association with an infective type of the disease. A case of a doctor infecting himself experimentally by inoculation has recently been recorded; this leaves no doubt on the point.

Infectivity of the Lepromatous and the Neural Types

In 113 of the 700 cases I collected the type of case from which infection was derived was recorded. In no fewer than 107, or 94.7%, it was a lepromatous case; this type is therefore five times as infectious as the neural type. Moreover, advanced neural cases may occasionally develop lepromatous lesions and become mixed cases; such may account for the few recorded infections from neural cases.

How far was that all-important fact recognized and acted on even 25 years ago? In 1922 I recorded a preliminary account of the epidemiological researches now being described (*British Medical Journal*, 1922, 1, 987). About three years later I heard from the Medical Secretary to the Government of South Africa that he was thus led to order a bacteriological examination of the 2,501 leprosy patients immured in prison-like asylums to determine how many of them were actually infective. This showed 603, a little later raised to over 800, to be uninfected neural ones, who had been segregated quite unnecessarily. They were accordingly released, with the happy result that very soon patients with early leprosy, who had become aware that an effective treatment was available for them (though the South African authorities had denied its value when they had only advanced unamenable cases in their asylum), flocked voluntarily to the new type of agricultural colonies which were now being supplied in South Africa, as advocated by me in 1920. It was then, and I believe still is, illegal for private practitioners to treat a case of leprosy; that was permissible only in Government leper institutions, except very rarely under home isolation.

Twenty-five years after the release of the uninfected cases I charted the data from the yearly South African reports. The total known cases had risen from 2,501 to 6,769 as the result of patients coming forward in the early stages. No fewer than 4,502, or 66% of that total, had passed through the agricultural colonies and had been discharged recovered; 61% of these had been free from active symptoms for over five years, so can be considered clinically cured. Nearly all the new admissions

of native patients are voluntary ones attracted by treatment the effectiveness of which is now generally acknowledged. That result is a great tribute to the value of the new method of control.

Children and Adolescents most Susceptible

An analysis of over 4,000 cases from four countries, in which data were available to enable the ages and the probable date of infection to be calculated, is tabulated on p. 71 of *Leprosy*. It establishes the important fact that approximately 50% of infections occur before the age of 20 years and 75% by the age of 30. After the latter age susceptibility is much less. Prof. Ehlers, in Iceland, as early as 1897 had recognized the great importance of prohibiting home isolation of leprosy patients if there were any children living in the house. As far back as 1890 missionaries in India had shown that a large proportion of the children brought up by leper parents became infected; but they nearly all remained free from the disease if maintained in a separate block of the same institution. This disproved the hereditary theory of the origin of the disease, which had been erroneously supported in 1863 by a Committee of the Royal College of Physicians of London. But how far was this crucial fact generally known and acted on 30 years ago?

Several thousand leprosy subjects lived a family life at Culion and scores of children were born to them. Two series of published data proved that 40% of those brought up by their parents for seven to ten years became infected from them! This has, of course, since been remedied.

I have therefore for several decades urged that the protection of children from infection is the key to the solution of the problem; this is now generally acknowledged. Moreover, house-to-house surveys in India, recorded by Drs. Muir and Cochran, have revealed that when young children live with a highly infective lepromatous case an average of two children per house were found to show early signs of the disease.

Incubation or Latent Period

Data which I worked out from Culion records showed the incubation or latent period between infection and the appearance of the first symptoms to average three and a half years. A further series which I collected from older literature, comprising 84 cases, showed an average period of two years eight and a half months. Moreover, in 81% of the series the period did not exceed five years, and it was scarcely ever over ten years. The old idea that it is frequently much longer is due to the early insidiously developing symptoms having for long been overlooked.

Plan for Control and Eventual Reduction of Incidence

The above conclusions form the essential basis of the plan I put forward in 1922 for the control of leprosy. The fact that some 80% of infections result from healthy persons, mostly children, residing, usually for years, in the same house as a previous case, indicates the necessity for the minute examination of every person living in the house of any newly discovered case, in order to find early cases amenable to treatment. If the newly discovered case is an infective lepromatous one the patient should be induced to enter an agricultural colony both for his own sake, to obtain treatment under the continued close supervision of an expert, and for the sake of his children and other relatives. Compulsion is now rarely required to induce him to do so; the real difficulty is the cost of providing accommodation for those willing to avail themselves of it. In India many have to be provided locally with at least a sleeping-place away from their households. If an infective patient cannot be removed from his home any children should be sent to healthy relatives. But that is not enough; for already infected members of his household will be liable to develop their first symptoms within the next five to ten years. They should all be carefully examined at least every six months for early amenable symptoms of the disease over a period of five or, better, ten years, and out-patient treatment at the nearest dispensary provided at a very low cost. The examination of school-children is another useful method of finding early cases.

Wherever that plan could be put into operation over a period of ten years the leprosy problem would be nearly solved, for the following reasons. The removal of the infective cases

to colonies would prevent further infections among the household and other close contacts. Those already infected would be discovered in a very early stage, and some 90% of them would be cleared of their symptoms and prevented from going on to an infective stage. The few who did so would be sent to colonies, and at the end of ten years scarcely any foci of infection would be left to carry on the disease; for lepromatous cases that have reached a stage unamenable to treatment live only for an average of eight to ten years, as shown by reliable U.S.A. records.

Empire-wide Trials of the New Methods

By far the most difficult task remained—namely, to organize efficient trials of the new methods under varying conditions in the Empire. For this purpose the British Empire Leprosy Relief Association was founded in July, 1923, and has worked ever since in cordial co-operation with the Colonial authorities. The results of those trials remain to be described. B.E.L.R.A., 167, Victoria Street, S.W.1, has recently published a pamphlet by me on the foundation and first 21 years of its work.

Nauru Island Epidemic

Leprosy was introduced into this small South Pacific island while under German rule, when in 1912 a leprosy woman was admitted from the Gilbert Islands. By 1920 she had infected three of the indigenous islanders, and the disease, helped by the depressing influence of an influenza epidemic and dietetic deficiencies, spread so rapidly that when in 1925, on my advice, all the indigenous population was carefully examined every month, 368 cases, or 30% of the people, were found to be infected. My plan was put into operation; 189 cases, already considered to be in an infective stage, were isolated on one side of the island and treated. The remaining uninfected ones were treated as out-patients and continued at work. Three years later Dr. Bray reported a decline of 40% in those still showing symptoms of leprosy. In 1933 Dr. Grant recorded a decline of nearly two-thirds of the total cases. The last available report—that for 1937 by Dr. T. M. Clouston—recorded that the total cases had been reduced to one-third of the number in 1927 and that approximately two-thirds of the remaining 159 cases were uninfected. By that time the total bacteriologically positive cases that had been isolated amounted to 284, and the early negative out-patient ones to 191, making a total in all of 477. There remained only 57 segregated infective cases (one-fifth of the total) and 102 uninfected clinical cases under treatment. The latter must mostly be cases whose first symptoms had appeared recently after several years' incubation. Only four of 176 originally infective cases had gone on to nodule formation, and during the last six years only five had become infectious skin cases, but not nodular ones; 32 nodular cases, or approximately 11%, had been released after having become bacteriologically negative.

This one of the worst epidemics ever known in proportion to the population involved had been brought under complete control. The conditions were, however, particularly favourable, with full authority over the people in a small area. Whether the disease would have been stamped out in time by this plan will never be known, for during the recent war the Japanese seized the island, and with their usual barbarity drowned the remaining patients.

Anglo-Egyptian Sudan Outbreak

A much more serious and difficult problem arose when yearly surveys for sleeping sickness cases in the humid Equatorial Province of the Sudan led to the discovery of many leprosy cases in a large area inaccessible during the rainy season. The P.M.O., Dr. Aikry, consulted me about it and arranged for the enumeration of the cases at the next annual survey, when 6,500 were found. Of these, 4,800 classed as infective were moved during 1927-30 with their families to large agricultural colonies on available and accessible vacant land, where provision was made for their regular examination and treatment. By 1934 7,075 cases had been admitted to the new settlements. As they had mostly been found in an early stage of their disease, no fewer than 3,679, or 52%, had already been cleared of their symptoms. Moreover, continued annual surveys showed that very few new cases were appearing in the originally heavily infected area from which they had been removed. The 1936 report stated that leprosy in the Sudan was well under control; doubtless much still remains to be done in that country as a whole.

British Guiana

The next step was to try to induce our smaller leprosy-infected colonies to relax their rigid compulsory segregation laws to allow early uninfected cases to be treated at out-patient dispensaries, at very small cost. West Indian tours by two successive B.E.L.R.A. secretaries failed to obtain even a trial of this obvious measure except in British Guiana. That Colonial Government accepted a B.E.L.R.A.

offer to provide funds for the construction of three leprosy clinics on condition that the suggested amendment of the law was made. In 1923 the only known cases were 267 advanced ones in the Manaiika Leper Institution. When the three clinics (later increased to 15) were opened and surveys made, so many infective cases were discovered or came forward voluntarily for admission to Manaiika that by 1932 747 were in residence. At the end of 15 years' work Dr. Rose recorded that 71.2% of regularly treated cases had had their disease arrested, but only 16.7% of those not submitting to regular treatment showed improvement. In 1941 there were 400 cases in the settlement—a decline of 46% since 1932—and 500 more were attending clinics, out of an estimated total of 1,000 in the colony. As the number of yearly discovered new cases had fallen, Dr. Muir reported that "there is good reason to believe that this decline in notifications is the result of an actual decrease of leprosy in the colony."

Ceylon

In 1921 there were 577 advanced leprosy cases under compulsory segregation. In 1930 our medical secretary, Dr. Cochrane, was consulted by the Government, and on his advice modern methods of control were introduced and the rigid provisions of the 1910 Leprosy Ordinance suspended. During the next two years surveys and propaganda and the establishment of clinics for early cases were carried out and new settlements on modern lines provided. Arrangements were also made for the repeated examination of contacts of all known cases to detect infections from them in an early amenable stage of the disease. By 1939 the known cases had risen to 3,618, 70% of which had been discovered by surveys. The number of isolated infective cases had risen to 1,031, but from 1941 onwards the yearly number of new cases declined and a start had been made in reducing the disease in the island.

Nigeria

Nigeria has the largest number of lepers in our Empire except India, with a high proportion of infective cases, and so presents a very difficult problem, on which the home committee of B.E.L.R.A. has largely concentrated its efforts. After Mr. Oldrieve's visit in 1926 a special leprosy officer was appointed, but the slump caused him to be axed in 1931, when nearly 6,000 cases were already under treatment. In 1926 Dr. Macdonald opened a large settlement at Itu, which in 1943 had some 2,400 inmates. Another, under Dr. Money, was opened in 1936 at Old River, which recently had 1,187 resident cases, and over 13,000 were being treated at a large number of satellite clinics. A third settlement, at Uzuakold under Dr. Davey, recently had 1,255 resident cases and 11,548 being treated at 43 outlying clinics. More important still, in this area a large proportion of the advanced infective cases were voluntarily isolated, with treatment, in 34 leper villages built at the cost of the chiefs. That these measures are already proving effective is shown by the fact that during a third house-to-house survey of 7,000 people of one tribe not a single unisolated advanced case was found; but 40 very early ones were detected, which should nearly all clear up with out-patient treatment. With continued frequent surveys, followed by treatment of all discovered early cases, there should be a rapid decline of the disease in such an area. Sir Bernard Bourdillon, when Governor of Nigeria, visited the Old River and Uzuakold leprosy settlements, and was so struck with the promising results already obtained that he procured a grant of £258,000 from the Colonial Development Fund, spread over five years, to enable the Nigerian Government to take over the work from the medical missionaries in charge and to extend it to other tribes, who were clamouring for similar help. This will allow B.E.L.R.A. to extend its pioneer work to other African colonies, until they too are educated up to taking over the control of leprosy in their territories.

B.E.L.R.A. may therefore fairly claim to have demonstrated the value of the recently introduced methods of treatment and prevention of leprosy under very varying conditions in widely separated portions of the British Empire. The more efficiently and extensively they can be put into operation the more rapid will be the decline in the incidence of the disease during the next two or three decades, imperfect though they may still be.

Need for Further Research on Treatment

It only remains to point out the need for continued research with a view to finding a treatment which will be effective in advanced lepromatous cases of leprosy. The triumphs of chemotherapy in recent years in discovering such potent remedies as the sulphonamides and penicillin encourage the hope of a real cure for leprosy being found before very long. Penicillin has so far shown no promise in this disease, but the intravenous use of the sulphone compounds promin and diasone in leprosy by Americans in Louisiana and by Muir in Trinidad has already yielded improved though still inadequate results

in lepromatous cases. Other such drugs are already available for trial—a slow and difficult operation on account of the long and variable course of the disease. It is hoped shortly to provide for an experienced whole-time research worker, who will have unlimited clinical material; success will greatly facilitate and hasten the eradication of leprosy from our Empire.

THERAPEUTIC ACTION OF DIFFERENT PENICILLINS ON SPIROCHAETA RECURRENTIS INFECTIONS IN MICE

BY

J. WILLIAMSON, B.Sc.Aberd.

(With a grant from the Medical Research Council)

AND

E. M. LOURIE, M.B.Lond.

Director of the Warrington Yorke Department of Chemotherapy,
Liverpool School of Tropical Medicine

It is now well established that there are a number of distinct but very similar penicillins, all characterized by a high degree of activity against certain pathogenic bacteria, combined with remarkable freedom from toxic effect on the host. Penicillins I, II, and III of Great Britain are recognized to be the same as penicillins F, G, and X, respectively, of the United States,^{1,2} and still further types have been identified. Preparations normally issued for therapeutic purposes contain a considerably higher proportion of penicillin II than of the other forms; yields from deep vat cultures are said to consist almost entirely of penicillin II, while those obtained from shallow surface cultures in flasks, although mainly comprising penicillin II, generally include moderate but varying proportions of penicillin III.³

Chemically these penicillins all have the same central structure, differing only in a side group,² and they vary somewhat in their selective potency against bacteria. For example, measured in Oxford units, although penicillin III is equally as effective as penicillin II against strains of *Staphylococcus aureus* and *Bacillus subtilis*, it was found to be two to eight times more effective than penicillin II against strains of streptococcus, pneumococcus, meningococcus, and gonococcus *in vitro*.^{4,5} This superiority seemed to be borne out in the treatment of gonorrhoea with penicillin III and II respectively.^{3,4} We refer to this work again below.

Crystalline penicillin II has a potency of about 1,650 units per mg., and crystalline penicillin III about 900 units per mg. Preparations normally issued for parenteral injection in clinical practice have fallen far short of these concentrations, and the Therapeutic Substances Act allows a potency as low as 150 units of undifferentiated penicillin per mg.,⁶ although earlier batches released by British producers contained two to four times this amount. More recently, some batches have been of the order of 1,000 units per mg., and it is expected that this standard of potency will become general.

An important contribution by Dunham and Rake⁷ has suggested that crystalline penicillin II is considerably less effective than partially purified preparations against *Spirochaeta pallida*. They worked with the Nichols strain of rabbit syphilis, and found that the spirochaetes were immobilized *in vitro* much more readily by impure preparations than by crystalline penicillin II; in fact, they were able to remove from the penicillin of partially purified samples a substance capable of immobilizing spirochaetes and resistant to the influence of penicillinase for eleven days at 37° C. Spirochaetes exposed to 1,100 units per ml. of certain partially purified preparations were non-infectious on intratesticular injection in rabbits, while spirochaetes exposed under similar conditions to 8,800 units per ml. of crystalline penicillin II gave rise to a specific orchitis.

In the experiments summarized below we have compared (a) partially purified penicillin as issued for parenteral injection, (b) crystalline penicillin II, and (c) crystalline penicillin III, in respect of their therapeutic action on *Spirochaeta recurrentis* infections in mice. It was trials against such infections (and those of *Spirillum minus*) which had previously led us to suggest that penicillin might be effective against human syphilis,⁸ as was in fact substantiated by Mahoney *et al.*⁹

Present Experiments

Mice were infected with *Spirochaeta recurrentis* by intra-peritoneal inoculation, and were then treated subcutaneously two days later, when wet blood films showed about 1 to 20 parasites per microscope field (oc. 4, obj. 1/6). The preparations of penicillin used were: (a) samples from eight batches of partially purified sodium penicillin of British manufacture, potency varying from 258 to 475 units per mg., as issued for parenteral use clinically, obtained through the Penicillin Clinical Trials Committee of the Medical Research Council; (b) two batches of crystalline sodium penicillin II, each of potency 1,600 units per mg., kindly supplied by Glaxo Laboratories Ltd.; and (c) two small quantities of crystalline sodium penicillin III, potency 680 and 635 units per mg. respectively, also supplied by Glaxo Laboratories. The penicillin preparations were dissolved in normal saline in concentrations such that treatment should be by 0.2 ml per 20 g of body weight.

Results and Discussion

Treatment was regarded as effective if the blood was cleared of parasites 24 hours later. The results obtained from individual batches did not differ significantly from one another.

Results of Treating *Spirochaeta recurrentis* Infections in Mice with Different Penicillin Preparations

Oxford Units Per 20-g. Mouse, Subcutaneously	Partially Purified Penicillin, as for Clinical Use	Crystalline Penicillin II	Crystalline Penicillin III
2,500 {	105 (94%) 112	47 (95%) 60	17 (49%) 35
1,000 {	51 (56%) 91	12 (52%) 23	13 (3%) 13
500 {	35 (30%) 118	15 (28%) 54	0 (0%) 27
250 {	0 (0%) 20	0 (0%) 8	0 (0%) 7

The denominator shows the number of mice treated, the numerator the number in which the blood was clear of parasites 24 hours later

within each of the three categories of penicillin preparations under trial, and aggregate findings for each of these three types of preparation are therefore summarized in the accompanying Table, from which the following arises

Crystalline Penicillin II—The partially purified preparations were not found to be more effective than the specimens of crystalline penicillin II, since the proportions of mice which responded to treatment, in these two groups, did not differ significantly at respective dose-levels. This is in line with the findings of Richardson *et al.*,¹⁰ working also with *S. recurrentis* (*Borrelia novyi*) infections in mice, but adopting somewhat different criteria of therapeutic efficacy. They also found no significant differences between the action of crystalline penicillin II and partially purified preparations (about 900 units per mg.—i.e. containing much less impurity than ours)

If Dunham and Rake's conclusions, quoted above, be applicable to human syphilis, the status of penicillin in the treatment of that disease will tend to deteriorate in the future as methods of purification become more and more refined and as batches released for clinical use accordingly become more and more free from impurities. It will then become increasingly necessary to investigate the anaspirochaetal properties of by-products in the manufacture of penicillin. If, on the other hand, the results of the experiments here recorded are a reliable index to the position in human syphilis, then the release of penicillin preparations of a higher and higher grade of purity presents no threat to the position of penicillin as a remedy for syphilis

Crystalline Penicillin III—This preparation proved to be substantially less effective than the other forms of penicillin tested. Thus, only 49% of 35 mice treated with 2,500 units of penicillin III responded favourably, as compared with 94% of 172 mice treated with the same dose of the other preparations. Applying the formula $\sqrt{(p_1 \times q_1)/n_1 + (p_2 \times q_2)/n_2}$ (see Bradford Hill¹¹), the difference between these proportions (45%) is 5.2 times its standard error (8.6). This means that, other factors being equal, the chances of such a difference arising merely through errors of random sampling are as little as 1 in several millions. The

difference is therefore highly significant statistically, and this is reinforced by the fact that at lower doses—1,000 and 500 units—penicillin III was practically ineffective whilst the other preparations produced a favourable response in a fair proportion of cases.

Again assuming that these results afford an index to the position in human syphilis, certain implications follow. As mentioned above, penicillin III has been found to exercise greater activity than the more easily obtainable penicillin II, or than partially purified preparations, against a number of bacteria, including the gonococcus.¹² It is stated to have the additional advantages of giving rise to higher and more sustained blood levels than these other forms of penicillin, after intramuscular injection of comparable doses.¹³ If these claims are fully confirmed it is likely that much effort will be directed towards improving methods of production and increasing supplies of penicillin III. While this will favour the campaign against gonorrhoea it will not have the same effect in regard to syphilis

It will be fortunate if it can be substantiated that, as the present work suggests, the more easily and more copiously produced form of penicillin—i.e., penicillin II—is also the more active against syphilis, since this disease demands such high aggregate dosage—perhaps twenty times or more for the average case of early syphilis than for the average case of uncomplicated gonococcal urethritis

Summary

Of the various identified forms of penicillin, that known as penicillin II in Great Britain (i.e., penicillin G in U.S.A.) appears in much greater proportion than any of the others, in batches ordinarily prepared for therapeutic use. Reports of other workers have suggested that crystalline samples of this form of penicillin may be less effective against syphilis than partially purified preparations, such as are normally issued for parenteral injection in clinical practice. If this be the case, then the status of penicillin in the treatment of syphilis stands in danger of deteriorating as production methods improve, with consequent release of batches of a higher and higher grade of purity. However, in so far as trials against *Spirochaeta recurrentis* infections in mice may be an index to the situation, the present experiments do not reveal any superiority of partially purified preparations over crystalline penicillin II.

Penicillin III (penicillin X of U.S.A.) is stated to be significantly more active than penicillin II, or than ordinary partially purified preparations of penicillin, against certain strains of streptococcus, pneumococcus, meningococcus, and gonococcus *in vitro*. It is also believed to have given better results than these other forms of penicillin in the treatment of gonorrhoea. The present experiments show, however, that it is substantially less effective than the other forms in the treatment of *Spirochaeta recurrentis* infections in mice.

The National Association for the Prevention of Tuberculosis has started a new quarterly magazine, *Health Horizon*, for the average reader. This periodical, edited by Dr. Harley Williams, will be by no means confined to tuberculosis. Its emphasis is upon ideas potentially useful in improving the health of the individual; and its aim is to give authoritative information, readably presented, to lay people not only in Great Britain but throughout the Empire, particularly the smaller Colonies. The price is 5s a year or 1s 6d a copy, and it is published by N.A.P.T., Tavistock House, Tavistock Square, London, W.C.1. The April number includes an article by Sir Harold Scott, F.R.S., on "Risks from our Animal Friends"; another on "D.D.T. and Health in the Tropics," by Mr. V. B. Wigglesworth, F.R.S.; and another on "Food Yeast," by Mr. L. D. Galloway. Dr. Douglas Guthrie writes on Arabian medicine; and there are also unsigned articles on paludrine (the new drug for malaria) and on mass miniature radiography.

NEUROGENIC ILEUS*

BY

JUDSON T. CHESTERMAN, M.R.C.P., F.R.C.S., F.A.C.S.
Surgeon, City General Hospital, Sheffield

Intestinal obstruction may be mechanical, vascular, or neurogenic in origin, and this paper is a consideration of the aetiology of ileus due to neuro-muscular imbalance. This aetiology will be discussed under three main headings: (1) intestinal movements and conduction, and their alteration in neurogenic ileus; (2) the sites of action of stimuli producing such alterations; (3) the factors giving rise to such stimuli in clinical practice.

Intestinal Movements

The two main purposes of intestinal movements are the passage of the intestinal contents from one segment to the next and the mixing of those contents, together with their application to the walls of the lumen so that absorption may be facilitated. Movements are brought about by contractions of the circular and longitudinal muscles of the bowel acting either separately or in conjunction with one another, and these contractions may or may not be associated with relaxation of the adjacent musculature. The common segmentation movements of the small intestine are brought about by localized contractions of its circular muscle occurring in rapid succession in adjacent areas, while pendulum movements, if such occur alone, are due to localized contractions of its longitudinal muscle. Contraction and relaxation of long segments of the intestine are produced by periodic alterations in tone in which contraction of both the circular and the longitudinal muscle leads to a decrease in the diameter and length of the affected area, and vice versa, during relaxation in the phase of diminished tone. These rhythmic segmentation and pendular movements are well suited for the mixing of intestinal contents, but they also tend to propel these contents in a caudal direction. Flatus and fluids are readily moved in that direction by increases of tone, though the effect on solids is negligible.

Peristalsis is the main cause of the movement of the contents in the small intestine, and the peristaltic rush formed by it consists of two factors—the muscular wave of contraction, and the movement of the fluid column produced by that contraction. Either factor may continue without the other through a relatively non-responsive segment of intestine and initiate a further peristaltic rush lower down the bowel, or both may fade out in a non-responsive area, which is usually an area of increased or rapidly altering tone. Peristalsis not only takes place out in areas of altered tone but may be initiated in areas of increased tone which appear during the cyclic activity of the bowel quite apart from the contents of the intestine in that area. The most common normal stimulus to intestinal peristalsis appears to arise as a wave in the duodenum, which starts just before a gastric contraction has reached the pyloric region, though peristalsis may arise in any part of the small intestine. In the common experimental animals and in man peristalsis normally passes in a caudal direction except in the first part of the duodenum and in the terminal ileum, where reverse peristalsis may be encountered.

The contents of the large intestine in man appear to be propelled by mass peristaltic movements. These usually arise in the caecum, often in response to the gastro-colic reflex, and push the intestinal contents into the transverse colon. This loading of the transverse colon may at appropriate times lead to a similar mass movement into the pelvic colon and rectum and so to the defaecation reflex and the emptying of the excretory part of the bowel.

It is apparent that the conduction produced by these movements is essentially unidirectional.

Gradients Theory of Polarity

This property of conduction in a caudal direction is known as the polarity of the bowel. Many theories have been proposed to account for this universally inherent property, which

causes the transmission of waves, fluids, and solids more readily in one direction than in another. The standard teaching is the so-called law of the intestine, which implies that excitation of any part of the gut produces contraction on the oral side and relaxation on the caudal side, so propelling its contents downwards. This conception cannot now be accepted, as peristalsis is very rarely initiated and practically never occurs in the manner suggested. This is undoubtedly fortunate, otherwise, as has been remarked, we should all be afflicted with intractable diarrhoea. However, Alvarez (1939) observed in the small intestine that there were definitely decreasing gradations in the activity, tonus, irritability, and rate of rhythmic contraction in passing from the duodenum to the lower ileum, and by analogy with the functional differences of the components of the cardiac musculature, which control the spread of a wave of contraction through the heart, he evolved the theory of gradients to account for the polarity of the bowel. Alvarez has established by an immense amount of work that gradients exist in the bowel for many of the common properties of its neuro-muscular mechanism and that these gradients decrease with the descent of the alimentary tract. He has been unable to show any basic gradient such as an anatomical or metabolic one which accounts for all the others; in fact, he has found that the gradients of tone, rhythmicity, etc., do not always vary together, so that one gradient may be flattened or reversed while the others remain normal. In those conditions in which there is reversal of certain gradients the polarity of the bowel is not fundamentally affected, so that his theory, though intimately connected with the polarity of the bowel, does not completely explain it. In fact, the explanation of polarity may be in the arrangement of the protein molecules themselves, so that there is a chemical and electric gradient ranging through them in a given direction and hence through the structure of an organ in the same direction (Ross Harrison, 1937, quoted by Alvarez). However, the observed facts in his theory of gradients do give the only physiological basis for certain alterations in the neuro-muscular balance of the intestine.

Flattened-gradients Theory of Neurogenic Ileus

Various factors alter the different gradients of the intestine, and these alterations may affect the whole or part of the intestine. The irritation of local inflammatory lesions has been shown to increase the rate of contraction and often to alter the tonus of the affected area. This may be due to an increase of the local metabolic rate from a local rise of temperature or through an alteration in the local blood supply, as intestinal activity is directly proportional to the blood flow through its musculature in perfusion experiments. Local or general effects upon the intestinal gradients may also be produced by the action of toxins and drugs, and there is no reason to doubt that nervous stimuli reaching the bowel may produce similar effects. In fact, Alvarez has shown that "any stimulation which raises the tonus, the activity, and the irritability of a segment of the bowel tends to slow the progress of waves and material approaching this segment on the oral side and to hurry the progress of material leaving it on the caudal side." I think that experimental and clinical evidence shows the converse is

FIG. 1.—Diagrams illustrating the theory of intestinal gradients. A, Possible alteration of gradients which may affect part or all of the intestine. (After Alvarez.) B, Effect of local steepening of gradients. (After Alvarez.) C, Effect of local flattening of gradients. (J. T. C.)

* Being part of an Arris and Gale Lecture delivered to the Royal College of Surgeons, May 11, 1945.

equally true: that any stimulation which flattens or reverses the gradients of a segment of bowel tends to increase the activity of the segment on the oral side and depress it on the caudal side for a variable distance (see accompanying diagram of theory of gradients).

That this local flattening of gradients does occur in man is shown by the following case reports as well as by experimental evidence to be presented later.

Case 1 (No. 166726).—A married nurse aged 26 was sent to see me by her private doctor. She had had attacks of abdominal pain for the past couple of years, with complete freedom between them for as long as three months. Attacks started with intestinal colic and cramp-like pain in the umbilical region, and the pain radiated through to the back. Sickness gave relief. The attacks lasted about 48 hours, and the patient had to go to bed on account of the pain. She suffered from nausea, flatulence, and constipation, but there were periods of complete freedom and no qualitative dyspepsia. Her menstrual history was satisfactory and there were no urinary symptoms. The patient was painfully shy, and admitted to a typical history of anal fissure of the same duration as her abdominal pain only after my finding it by rectal examination. An x-ray film of the abdomen, taken on account of the repeated vomiting, showed gaseous distension of a loop of upper jejunum, indicating some degree of local stasis. The N.P.N. was 28 mg. per 100 ml. Laparotomy (Jan. 12, 1944) under ether anaesthesia showed nothing abnormal, and a normal appendix was removed. The anal fissure was excised. The patient has remained symptomless for nearly two years.

Case 2 (No. 179471).—A female munition worker aged 22, married, was admitted complaining of severe continuous pain in the left iliac fossa for the past 12 hours, together with dysuria and frequency. She had suffered from mild attacks of intermittent intestinal colic in the same region, together with nausea and frequent vomiting, for the last three weeks. The bowel action was normal, and her menstrual history showed that the last period had been missed. On examination there was a tender cystic swelling in the lower abdomen about 3 in. (7.5 cm.) in diameter. An x-ray film taken on account of the repeated vomiting showed a distended loop of jejunum, and barium stopped in that loop for the 20 minutes during which it was being observed (see accompanying skiagram). Laparotomy was performed

no obvious barium. Below this area the gut was active, and was contracted to about 1 cm. in diameter. Skiagrams taken 24 hours after operation showed no abnormality, and the patient has remained symptomless. The N.P.N. was 25 mg. per 100 ml., and the fasting blood sugar 0.09%.

This local or general flattening of intestinal gradients, with its alterations in the motor function of the bowel, gives a satisfactory explanation of the mechanism of neurogenic ileus. In acute neurogenic intestinal obstruction these deviations are seen producing their maximum effect; but this is rare, though lesser degrees of ileus are extremely common.

The response of the gut, whether local or general, spastic or "paralytic" in nature, depends on the stimulus and its own condition when the stimulus is applied. It is known that a local stimulus usually produces a local effect in altering the gradients of the bowel, but there is little to indicate whether the result will be spastic or "paralytic" in nature or a combination of the two forms, though it seems certain that anoxia always produces spasm of the area involved, as also does degeneration of the ganglion cells of the myenteric plexus. Some stimuli lead to relative paralysis with distension—a distension which may terminate gradually or abruptly at its caudal end by passing into bowel of more normal size. It should be remembered, however, that the term "paralytic ileus" is a misnomer, as the bowel wall can almost always be made to contract in this condition by appropriate stimuli, this being so even when advanced diffuse peritonitis is present; so that "distensive ileus" is a better term.

The above explanation of the pathogenesis of neurogenic ileus infers that the type, spastic or distensive, the extent in length of the bowel involved, and the length of time the bowel remains in ileus are due to the stimuli and the condition of the bowel at the time of reception of those stimuli. So-called passive ileus is really an advanced stage of distensive ileus where venous stasis is marked and intramural strangulation is imminent, so causing lack of response, and corresponds to the addition of vascular obstruction upon a neurogenic ileus.

Levels in the Neuro-muscular Mechanism at which Ileus may Arise

It remains now to discuss the levels in the neuro-muscular mechanism of the bowel at which this imbalance may arise.

The work of Cannon and Murphy (1906, 1907) suggested that two distinct levels were involved, as they found that section of the splanchnic nerves stopped ileus due to the crushing of a testicle, but had no effect upon that produced by direct handling of the gut. Ochsner and his associates (1930a, 1930b, 1935), however, maintained that the giving of a spinal analgesic or a splanchnic block relieved the distension produced by handling the gut or by chemical peritonitis, and they introduced the treatment of so-called "paralytic ileus" by these methods. My clinical experience seemed to be at variance with this conclusion, hence the following series of experiments were carried out.

First of all confirmation was obtained of the value of spinal analgesia in the release of neurogenic ileus which had been produced by iodine irritation of the peritoneal surface of an area of bowel in dogs anaesthetized with a C.-E. mixture. The second step was to endeavour to induce neurogenic ileus in a dog while under spinal analgesia. It was found that 60 mg. of novocain injected intrathecally gave an excellent analgesia which reached well up the thorax and lasted several hours. Various forms of chemical peritonitis proved unsatisfactory owing to damage to the bowel wall or its blood supply, and the attempted production of bacterial peritonitis was also a failure, as in the event of its occurrence it was impossible to localize without gross trauma to the bowel wall, which vitiated the whole experiment.

After numerous trials it was found that the injection of several millilitres of methylated spirit between the leaves of the mesentery near the bowel margin produced a localized ileus in which the affected bowel distended and became filled with gas and led to a damming back of the intestinal contents on the oral side for varying periods up to several hours. These injections produced this result in all the ten dogs used, and was repeated several times in some of the dogs. In no case

FIG. 2.—Skiagram of Case 2. Note loop of upper jejunum retaining the barium meal.

under spinal analgesia (nupercaine 14 ml. 1/1500). The findings were: (1) Torsion of a serous cyst of the left ovary; this was removed. (2) Pregnant uterus, about 7 weeks. (3) The upper jejunum for about the first 18 in. (45 cm.) was dilated to a diameter of over 3 cm. This part, which showed active segmentation, was followed by 12 in. (30 cm.) of bowel which was inactive, which was about 2 cm. in diameter, and which reacted poorly to stimuli. It contained

could the effect be attributed to any alteration in the vascular supply of the area, so far as could be observed. It is interesting to note that in cats the same procedure carried out under intraperitoneal nembutal analgesia also leads to neurogenic ileus, but that in young animals it is often of a spastic rather than a distensive type.

These results have been confirmed in man, and the following is a typical example.

Case 3 (No. 168011).—A man aged 59 was admitted with some months' history of bowel irregularity. A spinal analgesic of 13 ml. of nupercaine 1/1500 was given without any premedication, and an operable carcinoma of the pelvi-rectal junction, not causing obvious obstruction, was found. A left inguinal colostomy was performed, then some 24 in. (60 cm.) of lower ileum was withdrawn and placed on moist saline towels. Vigorous intestinal movements were present except in the last few inches before the ileo-caecal sphincter. Some 2 ml. of 70% alcohol was injected between the leaves of the mesentery 18 in. (45 cm.) above the caecum; it caused a local whitening of the area of mesentery involved, but there was no visible alteration in the blood vessels of the area. Starting about two minutes after the injection, the adjacent intestine distended until it was nearly twice the diameter of the bowel above, and intestinal movements faded out as they entered it. The bowel below the 6 in. (15 cm.) involved by the distension showed marked decrease in movements, and normal movements were found only some 14 in. (35 cm.) below the upper limit of the distension. A local contraction could be produced at any point by direct stimulation. The condition persisted unchanged for the 20 minutes during which it was being observed before closure of the abdomen. Similar observations have been made on other patients, but it is interesting to note that in young adults investigated during an interval appendicectomy the reaction of the bowel was variable. Sometimes an area of spasm was produced; at other times distension occurred; while on occasions there was no obvious reaction.

These observations lend support to the flattened-gradients theory of neurogenic ileus and also make it reasonable to suppose that the so-called sympathetic inhibition of motor activity is not its only cause, but that ileus can arise from stimuli affecting the muscular or intrinsic nervous mechanism of the bowel.

Factors giving Rise to Neurogenic Ileus in Clinical Practice

So far we have discussed the mechanism of neurogenic ileus and the sites of action of stimuli producing it. Finally, it remains to mention the factors giving rise to such stimuli in clinical practice

- Traumatic**—(1) Local (a) intraperitoneal; (b) extraperitoneal.
(2) Remote
Infective—(1) Peritoneal: (a) local; (b) diffuse. (2) Extra-peritoneal. (a) intra-abdominal; (b) extra-abdominal.
Toxaemic—(1) Local. (2) General.
Idiopathic

This classification needs but little comment. Mild degrees of traumatic ileus occur after every laparotomy and recover spontaneously but occasionally the ileus persists, and when flatus has not been passed for 60 hours after an operation the condition is arbitrarily spoken of as "paralytic ileus." In a few cases the distension increases to such an extent that active measures have to be taken to alleviate the condition for fear of the possibility of intramural strangulation and to relieve pressure on the cardiovascular and respiratory systems. It is important to realize that neurogenic ileus in these cases either is a local condition, which if unrelieved may spread, especially if venous stasis occurs in the affected loops, or becomes a local condition after recovery from the initial post-operative general loss of tone and movement; and it is for this reason that the patient suffers from "windy pains" which, though not so severe, resemble those of mechanical obstruction. Retroperitoneal haemorrhage and injury to the lumbar vertebrae are also well-known causes. Ileus is well recognized as occurring in pneumonia, meningitis, and typhoid, as well as in intraperitoneal infections. Equally well recognized are the toxæmias of lead and of renal dysfunction, and ileus may occur in the latter with a rising or a falling N.P.N. Probably some idiopathic cases will on further investigation be found to be of reflex origin, possibly from atypical peptic ulcers situated distal to the duodenal cap, while others appear to be associated with hyperglycaemic attacks unassociated with glycosuria or renal failure.

Conclusions

Neurogenic ileus is due to a local or general flattening of intestinal gradients.

It may be spastic or distensive in type, and the factors producing it may affect the extrinsic nerves or act directly upon the neuro-muscular mechanism of the bowel.

The symptomatology is in accordance with the factor causing the ileus and the type of ileus, plus the site of the obstruction, the degree of obstruction, and the length of bowel involved.

So-called passive ileus is a distensive ileus in which venous stasis has become so marked that a vascular intramural obstruction complicates a neurogenic ileus.

Thanks are due to the Medical Research Council for making this work possible, and to Prof. H. N. Green, Department of Pathology, Sheffield University, in whose department most of the experimental work was performed.

THE DIETS OF FAMILIES WITH CHILDREN IN 1941

BY

E. R. BRANSBY, Ph.D.

The tables given in *Food Consumption Levels* (H.M.S.O., 1944) show that there were considerable differences in the consumption of foods and nutrients during the war compared with pre-war and also in the different war years. From the point of view of food supplies 1941 was the most difficult year. It was also a time of transition between pre-war, when there was no food rationing and few welfare food schemes, and the later years of the war, when there were an extensive rationing system and a relatively highly developed system of welfare schemes and priority allowances. The following information, derived from a dietary survey in 1941, is of interest because it relates to that difficult transition period.

Collection and Analysis of Data.—The survey was made by the Ministries of Food and of Health in 1941. The original plan was to re-survey those families surveyed previously in the Carnegie (1937-8, unpublished), West Riding (County Council of the West Riding of Yorkshire, 1939), and London (Bransby and Bransby, 1940) studies. As the large majority of the families could not be traced a random selection of families living in working-class districts of London, Preston, West Riding, Smethwick, Oxford, Glasgow, Aberdeen and district, and rural parts of Somerset was taken. Data were collected from approximately 100 families in each locality, except Oxford, where the sample was 152 families. The survey was limited to families with children, as only such families had been included in the previous surveys. The field work lasted from March to December, 1941, and the precise weighing technique (Cathcart, 1931-2) was used for collecting the information from housewives. The composition of the diets has in the main been calculated from *Nutritive Values of Wartime Foods* (M.R.C. War Memo. No. 14, 1945). The League of Nations standards of nutrient requirements (Magee, 1943) have been used to assess the nutritional adequacy of the diets.

Changes in Economic Conditions.—Although the survey was made early in the war, considerable economic changes had already taken place since pre-war. Earnings increased by 29.9%, 42.4%, and 46% in July, 1940, July, 1941, and January, 1942, respectively, compared with October, 1938 (Ministry of Labour and National Service, 1942), and the price of food, according to the Food Index, rose by about 25% between March/August, 1939, and March/December, 1941. Such changes make comparison between the present data and pre-war food consumption data hazardous, and consequently is not attempted here.

Food Rationing and Allowances.—During the survey period the ration allowances per head weekly were: bacon, 4 oz.

(113 g.); sugar, 8 oz. (227 g.), with a short period of 12 oz. (340 g.); meat, 1s. to 1s. 2d. (holders of a child's ration book, half these amounts); for about the first two months cheese was unrationed, and for the rest of the survey period the ration was 1-3 oz. (28-85 g.); butter and margarine, 6-7 oz. (170-198 g.), cooking fat, 2-3 oz. (57-85 g.). Preserves were rationed at 8-16 oz. (227-454 g.) per month. The milk-in-schools scheme and the national milk scheme were in operation, but the welfare vitamin schemes were not. The school meals service was operating only to a very limited extent. The distribution of national household milk and the "points" rationing scheme began during the last month of the survey. Margarine was fortified at the rate of 450 i.u. of vitamin A and 30 i.u. of vitamin D per oz. (28.35 g.) Although national bread (85% extraction flour) was on sale its consumption was small, the great bulk of the flour used during the survey period being about 75% extraction

Results of Survey

Family Constitution.—Table I shows the average composition of families, grouped according to food expenditure per head. An important feature is the fall in the number of children per family with increasing food expenditure per head.

TABLE I—Average Family Composition according to Food Expenditure per Head Weekly

Group	1	2	3	4	5	6
Food Expenditure per Head Weekly	Under 5s	5s-7s	7s-9s	9s-11s	11s-13s	13s and Over
Children	4.6	3.3	2.5	1.8	1.4	1.0

* As liquid milk equivalent: consists almost entirely of liquid milk. (1 pt = 568 ml., 1 oz = 28.35 g.)

The most noteworthy feature of Table II is the increase in the consumption of most foods with increasing expenditure per head. The only exceptions are margarine, potatoes, and oatmeal, although the increases in the consumption of total fats and sugar are relatively small. For the protective foods the differences are considerable. Comparison of the data of the "under 5s" group with those in the "13s. and over" group shows that consumption in the latter exceeded that in the former by 90% for milk in all forms, 200% for cheese, 290% for eggs, 160% for meat, bacon, and offals (due partly to the large proportion of children in the "under 5s." expenditure group), 490% for fish, 215% for vegetables, and 1,700% for fruit.

Of the total liquid milk supply of the households 56%, 51%, 42%, 29%, 28%, and 13% was obtained under the national milk scheme and the milk-in-schools scheme in the under 5s., 5s.-7s., 7s.-9s., 9s.-11s., 11s.-13s., and over 13s. food expenditure groups respectively. It must be pointed out that some of the above differences are due to the higher proportion of children in the lower food expenditure groups.

Nutrient Intakes.—Table III shows the nutrients obtained per head daily from the diets listed in Table II, and Table IV the percentages these represent of requirements according to League of Nations standards. In both Tables III and IV allowances have been made for cooking losses of vitamins (M.R.C. War Memo No 14, 1945).

TABLE III—Intake of Nutrients per Head Daily

Food Expenditure per Head Weekly	Prot. (g)	Fat (g)	Carb. (g)	Calcs. (mg)	Calc. (mg)	Iron (mg)	Vit. A (i.u.)	Vit. B (i.u.)	Ascorbic Acid (mg)
1 Under 5s	57	55	270	1,803	430	8	2,062	214	15
2 5s-7s	63	63	287	1,967	493	9	1,828	237	20
3 7s-9s	68	75	292	2,115	556	10	2,620	257	23

TABLE IV—Nutrient Intakes Expressed as Percentages of Requirements according to League of Nations Standards

Food Expenditure per Head Weekly	Protein (g)	Calcs	Calcium (mg)	Iron (mg)	Vit. A (i.u.)	Vit. B ₁ (i.u.)	Ascorbic Acid (mg)
1 Under 5s	95	88	37	82	70	81	51
2 5s-7s	100	89	44	89	62	87	61
3 7s-9s	106	93	51	96	89	94	73
4 9s-11s	115	98	59	115	99	93	100
5 11s-13s	123	102	69	127	112	103	113
6 13s and over	136	109	86	137	129	110	133

For all nutrients the adequacy of intake increased with increasing food expenditure per head. The most severe deficiencies according to the standards adopted were in calcium, vitamin A, and ascorbic acid, although for the food expenditure groups of under about 9s. per head weekly there was a deficient intake of all nutrients except protein. The intakes of animal protein were about 17 g., 21 g., 26 g., 31 g., 33 g., and 43 g. per head daily in the groups with weekly per head food expenditures of under 5s., 5s.-7s., 7s.-9s., 9s.-11s., 11s.-13s., and 13s. and over respectively, these representing 29%, 33%, 38%, 40%, 41%, and 46% of the total protein intakes. In all groups about 70% of the total vitamin potency of the diets came from preformed vitamin A. It is instructive to observe that in the lower food expenditure groups the average intakes of ascorbic acid were only about 15 to 20 mg. daily.

Consuming Habits

During the survey the housewives recorded the meals eaten by the members of their families, and these data were analysed to show the meals eaten by mother, father, other adults, adolescents aged 14 to 18 years, and children aged 2 to 14 years. The object of the analyses was to compare consuming habits of the families in the various food expenditure groups and to determine whether the diet of any group was so monotonous as to be a danger to morale. The meals consumed were grouped into:

Drink Only.—Tea, coffee, cocoa, or other beverage without any other food.

Bread and Spread.—Bread with butter, margarine, dripping, jam, treacle, fish paste, or any other such spread.

Cereal.—Oatmeal, porridge, cornflakes, or any other such cereal food.

Cooked Meal.—Any such meal as eggs, bacon, sausage, cooked meat, or vegetables, or cooked food eaten cold.

Pudding.—The commonly accepted meaning.

Pie Meal.—Meals consisting of meat or fish pies.

Meat Sandwich.—Bread with filling of cold cooked meat, sausage, canned meat, or similar food.

Table V shows the percentages of the persons eating the above meals in each of the six food expenditure groups. The

"drink alone" figures have been omitted from the breakfast, dinner, and tea sections of Table V, for in no food expenditure group did these meals consist to any extent of drink alone.

In the discussion below the food expenditure groups are referred to by numbers: (1) = under 5s.; (2) = 5s.-7s.; (3) = 7s.-9s.; (4) = 9s.-11s.; (5) = 11s.-13s.; and (6) = 13s. and over.

Breakfast.—"Bread and spread" was taken by 71-93% in Group 1, this being progressively reduced to 15-30% in Group 6. Cereals were taken by 20-30% in almost all groups. In Group 1, 5-8% had a cooked meal, increasing progressively to 31-58% in Group 6; the

The principal differences shown by the above analyses are that as food expenditure increased so there was (1) a decrease in the frequency of "bread and spread" for breakfast, dinner, tea, and supper, of cooked meals for dinner, and of drink alone for supper; and (2) an increase in the frequency of cooked meals for breakfast, cooked meals and pudding for dinner, cake for tea, and cooked meals or sandwich for supper. The variations between the different individuals of the family were not so marked, and occurred mainly at breakfast and tea.

Comparison of Food Expenditure Groups.—Table VI shows the number of "drink alone" or "bread and spread" meals

TABLE V.—Percentage Frequency of Various Types of Meals

Food Expenditure Group:	Mother						Father						Other Adults						14-18 Years						2-14 Years

1* = under 5s.; 2* = 5s.-7s.; 3* = 7s.-9s.; 4* = 9s.-11s.; 5* = 11s.-13s.; 6* = 13s. and over.

greatest difference was between the two lowest groups. Cooked meals and cereals were seldom consumed in Group 1 and infrequently in other groups. In Group 1 6-8%, and in Group 6 49-63%, took a cooked meal or a cooked meal with cereal. Considering the types of meals taken by individuals, the frequency of "bread and spread" was the same—73-76%—in Group 1 by father, mother, adolescents, and children. The frequency fell for all persons to Group 6, but father tended to have it slightly less often and mother more often than the remainder. Thus in Group 6 the frequency of "bread and spread" taken by mother, father, adolescents, and children was 30%, 15%, 17%, and 17% respectively. Cereals were taken somewhat more often by children. Cooked meals with or without cereals were taken most often by father and other adults, and then by adolescents.

Dinner.—"Bread and spread" was consumed by 0-10% in Group 1 and 7-12% in Group 2, but only by 0-3% in Group 6. Cooked meals were taken by 64-77% in Group 1, this being progressively reduced to 25-30% in Group 6. There was a reverse trend in cooked meals and puddings—10-23% in Group 1 and 65-70% in Group 6. Thus 85-93% in Group 1 and 93-99% in Group 6, of all persons, had a cooked meal with or without pudding for dinner. The frequency of "bread and spread," cooked meals, and cooked meals with pudding did not vary much between persons.

Tea.—In Group 1 "bread and spread" was consumed by 36-47%, this being reduced progressively to 6-10% in Group 6. On the other hand, cake for tea became more frequent from Group 1, where it was taken by 7-19%, to Group 6, where it was taken by 45-58%. The frequency of cooked meals was fairly constant in all groups—about 30-40%.

There was little variation in the frequency of the taking of "bread and spread" or cake for tea by individuals. Mothers and children took a cooked meal slightly less frequently than did fathers in Groups 4, 5, and 6. Adolescents in Groups 1 to 4 had a cooked meal about as often as adults, but slightly less so in Groups 5 and 6.

Supper.—The frequency of drink alone fell from 15-22% in Group 1 to 6-11% in Group 6, and that of "bread and spread" from 57-71% to 33-51%. In Group 1 a cooked meal was eaten by 5-13%, this being progressively increased to 17-28% in Group 6. Meat sandwich was quite popular, especially in the families with the highest food expenditure: 21-32% in Group 6 and 2-6% in Group 1.

Little difference was observed in the frequency with which various types of meals were taken by individuals, although there was a tendency for children to have drink alone or "bread and spread" more often and a cooked meal less often than other persons.

and the number of cooked meals, with or without puddings, taken daily per head by the persons falling into the various food expenditure groups.

TABLE VI.—Daily Frequency of Various Kinds of Meals according to Food Expenditure per Head

	Under 5s.	5s.-7s.	7s.-9s.	9s.-11s.	11s.-13s.	13s. and Over
Drink alone or bread and spread	2.3	1.6	1.3	1.1	0.9	0.8
Cooked meal	1.4	1.6	1.8	1.8	1.9	2.1

The number of meals consisting of drink alone or of "bread and spread" fell progressively from Group 1 to Group 6, but that of cooked meals rose. Comparison between Groups 1 and 6 shows that the poor families had "bread and spread" or drink alone about three times as frequently as the better-off families. Over one-half of the meals of the former consisted of "bread and spread."

It is apparent that the families of the lower food expenditure groups were receiving a monotonous diet, and this may have been a cause of the low calorie intakes shown in Tables III and IV despite the availability of unrationed foods such as bread and potatoes.

Discussion

Despite rationing and the introduction of the national milk scheme there were wide differences in 1941 in the consumption of foods and the nutritional adequacy and palatability of the diets consumed by families when grouped according to food expenditure per head. Particularly low, according to the standards adopted, were the intakes of calcium, vitamin A, and ascorbic acid; but, despite this, there was no evidence of a prevalence of clinical signs of ascorbic acid deficiency throughout the country. It is emphasized that the position as shown in this survey relates specifically to 1941. Subsequently the control of food distribution developed in a number of respects which must have flattened some of the trends shown in Table II.

Summary

A dietary survey of 849 families was made in 1941 in eight localities in England and Scotland.

The consumption of most foods, and especially protective foods, was considerably greater among families with high than among those with low food expenditure per head. The intake of all nutrients except protein was inadequate among the groups with food expenditures of less than about 9s. per head weekly, and the calcium intake was inadequate among all groups, irrespective of the level of food expenditure. Particularly deficient were the intakes of calcium, vitamin A, and ascorbic acid.

Data are presented on the types of meals eaten by persons of different ages in the various food expenditure groups. A summary cannot succinctly be made, but it is shown that the diets of the poor families were much less varied than those of better-off families.

Thanks are due to the Registrar-General's Department and the medical officers of health of the localities in which the survey was made for help in the selection of the survey sample. The field work was done by Miss Jackson, Miss Hartley, Miss Canney, Mrs. Caffrey, Miss Lloyd Evans, Miss Cooper, Miss Campbell, Mrs. Thompson, and Mrs. Bransby. Thanks are due to the director and staff of the Rowett Research Institute for assistance and for providing the lists of informants in the Carnegie survey. The Ministries of Food and of Health are thanked for permission to publish this paper.

EXTRA-ORAL NERVE-BLOCK ANALGESIA FOR DENTAL EXTRACTIONS

BY

H. M. WOOD, M.B., Ch.B., B.Sc., D.A.

K. M. RAINS, M.R.C.S., L.R.C.P., D.A.

AND

P. A. BRAMLEY, B.D.S., L.D.S.

Analgesia of the fifth nerve by the extra-oral approach was first described by Braun in 1905. The technique that we have used in this series was described by Labat in 1922. Although intra-oral nerve block is a daily matter in dental surgery, the external approach has never been popular, chiefly owing to the need for an absolutely aseptic technique, almost impossible to obtain in dental surgery.

The advantages of extra-oral nerve block in dental surgery were impressed upon us by the type of cases on which we were asked to operate; all were patients at the Queen Elizabeth Hospital, Birmingham, the majority of whom were suffering from subacute bacterial endocarditis, the others from congestive heart failure or severe asthma. The patients all had gross dental sepsis, which precluded intra-oral injections, while their condition made general anaesthesia inadvisable. This method proved very satisfactory, and without its use the dental treatment could not have been carried out without subjecting the patient to grave risk.

In order to overcome the acute shortage of hospital beds we used this technique on 21 selected out-patients; they were all co-operative, and indeed preferred the method to a stay in hospital and a general anaesthetic. Other conditions in which extra-oral block is indicated are acute inflammatory conditions of the jaw, fractures of the mandible, and cases in which trismus renders intra-oral injection impossible. When there is oral sepsis any injection within the mouth is dangerous, mainly because the injection of fluid under pressure damages the tissues and renders them more liable to infection. With extra-oral blocks all injections are distant to any possible sepsis.

Premedication

As many of the patients had been ill for a long time, especially those with endocarditis who were having three-hourly intramuscular injections of penicillin, and were apprehensive, adequate premedication was essential. We found that it was not necessary to premedicate as heavily as is customary when the same nerve blocks are used in intranasal surgery. We should like to stress the importance of the tactful handling of the conscious patient, both by the anaesthetist and by the surgeon.

Even heavy premedication will be useless if the patient becomes nervous. The out-patients were not premedicated; they walked into the theatre and had the injection and extractions immediately. Their bearing during the operation and their comments afterwards were very satisfactory. The omission of premedication, however, is practicable only if the patient's temperament is suitable.

Nerve Block

The nerve supply of the upper jaw is from the second or maxillary division of the fifth cranial nerve. The maxillary nerve leaves the skull through the foramen rotundum, crosses the upper part of the pterygo-palatine fossa, and enters the orbit through the inferior orbital fissure. The maxillary nerve is therefore accessible in the pterygo-palatine fossa and can be approached by two routes, both of which we have used in this series: (1) through the incisura of the mandible just below the mid-point of the zygoma (posterior zygomatic approach); (2) through the angle formed by the anterior border of the masseter muscle and the inferior margin of the zygoma (anterior zygomatic approach).

In this series we have used the anterior approach in 35 and the posterior approach in 21 cases. We have found that the anterior approach is easier to perform, reliable, and much more pleasant for the patient. Haematoma of the cheek, which is mentioned as a complication in all the literature, we saw twice, both in the same patient, who at the time complained that she was bruised at the site of her intramuscular injections of penicillin. At the Radcliffe Infirmary, Oxford, where this approach is used as a routine in the E.N.T. department, Dr. W. W. Mushin tells us that a haematoma of the cheek has never been seen. We now use the anterior approach in all cases.

The nerve supply of the lower jaw is from the third or mandibular division of the fifth cranial nerve. The mandibular nerve leaves the skull through the foramen ovale, and after a course of 2 to 3 mm. divides into its various branches. It can therefore be anaesthetized as it leaves the skull, while, for dental extractions only, the inferior alveolar nerve can be anaesthetized just before it enters the mandibular foramen, the lingual nerve being anaesthetized at the same time. The surface marking for the mandibular nerve block is the same as for the posterior approach of the maxillary nerve—namely, through the incisura of the mandible immediately below the zygoma. The site of injection for the inferior alveolar nerve block is 1 cm. behind and below the angle of the mandible. Care must be taken that the analgesic solution is not injected into the insertion of the internal pterygoid muscle.

In this series we have used the mandibular nerve block on 36 and the inferior alveolar block on 20 cases. We have found that the inferior alveolar approach is more pleasant for the patient; it is very reliable and extremely easy to perform. The results have been satisfactory on all occasions, and patients tolerate it better than the mandibular route. As the duration of the operation has not been expected to exceed one hour we have used a 2% solution of procaine with 1:400,000 adrenaline. No solution is injected into the patient unless the aspiration test is negative, so it is essential to use a glass-barrelled syringe.

Comment

Operating conditions given by the extra-oral method of analgesia are good. The duration of analgesia, using procaine, has been up to two hours, and a full hour's operating time can be relied upon. Bleeding has been noticeably less than under a general anaesthetic, although of course the field is not as bloodless as when a local infiltration is used. There have been no complications such as dry socket, necrosis, or tissue-sloughing. Healing has been as quick and uneventful as that after a general anaesthetic.

We have noticed the following minor complications: transient sixth-nerve paralysis; slight facial paralysis in four cases, which passed off within the hour; and temporary swelling of the cheek due to an excessive amount of solution injected. We have already mentioned one case of bruising.

Summary

Dental extractions under extra-oral nerve-block analgesia were performed in 112 cases.

The patients were of the "poor risk" type of out-patients.

The anterior zygomatic approach for the upper jaw and the inferior alveolar nerve block for the lower jaw were found preferable both by the anaesthetist and by the patient.

It should be emphasized that the procedure should be carried out only under absolutely aseptic conditions. The aspiration test must always be negative.

Extra-oral nerve-block analgesia has been found excellent for patients with gross dental sepsis, especially now that the use of penicillin has made it possible to treat the dental sepsis of those patients with subacute infective endocarditis; and also for those with heart failure with orthopnoea and those with asthma.

From the dental point of view there have been no complications, the healing of the tissues being quicker than when local infiltration is used.

Our thanks are due to Mr. Harold Round, M.D.S., for his great help and encouragement, and to Prof. K. D. Wilkinson, who provided us with most of our clinical material. Finally, we acknowledge with gratitude the teachings of the Nuffield Department of Anaesthetics at Oxford.

Medical Memoranda

Paradoxical Embolism

Paradoxical embolism can occur only if there is direct communication between the auricles or the ventricles. A patent foramen ovale, which is found in a third of all necropsies, is ordinarily a fine slit in the edge of the fossa ovalis, the membrane acting as a flap-valve which is virtually closed during life. A wide opening in the interauricular septum is a rare condition. In both cases the physical signs may be normal. In the case of the flap-valve an embolism could pass from right to left auricle only if the pressure in the right auricle became higher than that in the left. In a recent article Birch (1945) mentioned two ways in which this might occur. A previous embolism lodging in the pulmonary artery might raise the pressure in the right auricle, or the embolism might coil up over the tricuspid valve and block it sufficiently to cause the momentary rise of pressure necessary to open the valve in the foramen ovale and allow that embolus, or emboli following immediately after, to pass into the left auricle. This latter mechanism, first suggested by Porter (1941), seems the most probable explanation of the following case, in which previous monary embolism was excluded by clinical and post-mortem mination.

CASE REPORT

A woman aged 42, seen in consultation with Dr. H. L. Heath, of Evesham, had a subtotal hysterectomy performed for metropathia haemorrhagica on Nov. 15. She made satisfactory progress until six days after the operation, when she was noticed during the night to have developed a left-sided hemiplegia. Examination at the same time revealed evidence of arterial obstruction involving the whole of the right leg. The heart and lungs appeared normal. The circulation gradually returned to the right leg, but she died eight days later. Post-mortem examination showed a slit-like opening at the edge of the fossa ovalis, the membrane forming a flap-valve on the left side of the foramen. The pulmonary arteries and lungs were normal. There was an embolism lightly adherent to the wall of the lower end of the aorta and the proximal inch (2.5 cm.) of the right common iliac artery, and there were several recent infarcts in the right kidney and the spleen.

Pregnancy in a Uterus Bicornis

With reference to the case of pregnancy in a uterus bicornis in the *British Medical Journal* of Dec. 22, 1945 (p. 894), the following case of a ruptured bicornuate pregnancy may be of interest.

CASE HISTORY

The patient, Mrs. A., aged 24, primigravida, and 38 weeks pregnant, was admitted to the Anlaby Road Hospital, Hull, at 6.45 a.m. on Dec. 11, 1945. At 12 weeks she began to have central abdominal pains, which were colicky in nature, lasting on and off for one month, with also seven days' vaginal bleeding. At the end of the month she passed a small "piece of membrane." On Dec. 10, while being x-rayed lying on her abdomen, she had severe central

abdominal pains, which were colicky and aggravated by movement and she also vomited several times.

On examination (Dec. 11) the tongue was clean; temperature 98.4° F. (36.9° C.); pulse rate 90 per minute; blood pressure 138/98. The uterus by palpation was found to be the size of a 38 weeks pregnancy, with the presentation a breech. The foetal part were easily palpated and the foetal heart was heard easily. She was very tender above McBurney's point, with no rebound sign. There were shifting dullness in both flanks and tenderness in both loins. Per vaginam, the os was closed and there was no bleeding. Two hours later the temperature was 99° F. (37.2° C.) and the pulse rate 104. In view of the rising pulse and temperature a tentative diagnosis of acute appendicitis was made.

Operation.—This was carried out under gas-oxygen and ether anaesthesia. The abdomen was opened through a right paramedian incision and free blood was present in the abdominal cavity. A male child was found with the head lying among small intestine and covered with omentum, while the breech was still partially inside a thin membranous sac, which was seen to be the ruptured right horn of a bicornuate uterus. After delivery of the child the placenta with the right horn was removed. After removal the uterus was almost like a normal one in shape and about 5 in. (12.5 cm.) long, with both tubes and ovaries in the usual position. The abdomen was closed without drainage. The child revived satisfactorily—weight, 6½ lb. (2.95 kg.). Mother and child were discharged three and a half weeks later.

On dissection of the placenta away from the uterine wall the latter was seen to be extremely thin, and it was surprising that rupture had not taken place earlier in the pregnancy.

I am indebted to Dr. N. Gebbie, medical officer of health, Hull, Dr. D. L. McRae Tod, and Mr. C. H. Corbett for permission to publish this case.

D. W. ROBINSON, M.B., Ch.B.,
Anlaby Road Hospital, Kingston-upon-Hull

Schönlein-Henoch Purpura with Blood in the Cerebrospinal Fluid

Cases of Schönlein-Henoch purpura with blood in the cerebrospinal fluid are exceedingly rare. Dr. Eli Davis, of St. Andrew's Hospital, L.C.C. (personal communication), informed me that, among 1,100 cases of all kinds of purpura, in only two was there blood in the cerebrospinal fluid. I therefore report the case below, the cause of which, in view of the very high anti-streptolysin titre and previous sore throat, was probably streptococcal.

CASE HISTORY

A child aged 7 was admitted to hospital on July 18, 1944, with a two-weeks history of malaise and sore throat. Three days before admission painful swellings in both knees and elbows appeared.

Examination showed a slender pale girl with temperature 100.5° F. (38.05° C.) and pulse 130. She had a dry and coated tongue with severely injected fauces. The submandibular glands were enlarged and tender. The elbows, wrists, and knee-joints were also very tender, with periarticular swelling, while the shoulders were painful. Full doses of salicylates were given. Next day the temperature rose to 102° F. (38.9° C.) and the pulse to 170. The backs of the hands became swollen and there was an extensive and alarming swelling of the neck. Two days after admission petechiae appeared on the buccal mucous membrane, right shoulder, and both gluteal regions, while the neck swelling further increased, but there was less fever. In the next few days the swelling of the neck began to subside, but new crops of petechiae appeared on the ankles, dorsum of feet, and soles. One week after admission the temperature rose again to 100° F. (37.7° C.) and the child complained of spasms of pain round the umbilicus and passed melaena stools. There was some albuminuria but no haematuria. A few days later the skin of the palms began to peel. The general condition showed some improvement, with fading of the petechiae, though the temperature still remained at 100°. Twelve days after admission she complained of frontal headache and showed slight neck rigidity and a positive Kernig sign. A lumbar puncture revealed marked xanthochromia, a heavy excess of globulin, and a positive indirect van den Bergh test. Although no organisms were seen and the culture remained negative, a course of sulphamezathine was given—without obvious effect. Three days after onset of meningeal symptoms her condition began slowly to improve, and one month after admission the temperature settled and the blood count was normal. The child was discharged quite well on Aug. 30, and has remained well.

Investigations.—July 19: W.B.C., 28,000 per c.mm. (polymorphs 81%, lymphocytes 15%, monocytes 4%). July 22: W.B.C., 14,800 per c.mm. (polymorphs 76%, eosinophils 3%, lymphocytes 16%, monocytes 5%). July 25: W.B.C., 12,800 per c.mm. (polymorphs 81%, eosinophils 2%, lymphocytes 27%); platelets, coagulation time, normal; blood culture, negr swabs, negative to streptococci. Anti-streptolysin titre at height of illness, 1,250 units (normal is 50-150 units); anti-histase, normal (Dr. E. W. Todd). Blood sedimentation rate (Westergren), 70 mm. first hour. July 30: Cerebrospinal fluid.—White cell count, 135 per c.mm. (polymorphs 50%, lymphocytes 48%, endothelial 2%); R.B.C., 600 per c.mm.; protein, 120 mg. per 100 ml.; chlorides and sugars, normal; no organisms seen on a stained film; culture negative.

I thank Mr. J. R. M. Whigham, F.R.C.S., and Dr. Eli Davis for their help.

Reviews

PATHOLOGY OF TROPICAL DISEASES

Pathology of Tropical Diseases. An Atlas. By J. E. Ash, Director, and Sophie Spruce, Pathologist, U.S. Army Institute of Pathology, Army Medical Museum. (Pp. 70, 941 illustrations, 4s.) London: W. B. Saunders Company, 1945.

The authors of this publication have felt that in books dealing with tropical diseases the subject of pathology has received only casual reference. To fill the gap thus created they have produced this atlas which describes and depicts in a long series of illustrations (mostly photographs of disease conditions of the body and organs and photomicrographs of histopathological changes) all the salient aspects of the pathology of tropical diseases. In addition to the purely pathological study under each disease is given a short and concise account of its aetiology, epidemiology and clinical features supported where necessary by maps illustrating distribution and life cycles of the causative organisms. In all there are 257 plates comprising 941 illustrations of which 15 are in colour. These are excellently reproduced, and with their descriptive labels cannot fail to be of great value to students of tropical medicine.

The book is divided into a series of chapters each with its list of references to the literature. The first two deal with virus diseases. There then follow chapters on Bartonellosis, rickettsial diseases, tropical treponematoses, and spirochaetal diseases. A chapter on the dysenteries is followed by others on bacterial diseases, leprosy, and fungoid diseases. The protozoa—trypanosomiasis, leishmaniasis, and malaria—are then considered and four chapters are devoted to the helminths—nematodes, trematodes, and cestodes. Finally environmental factors, deficiency diseases, tropical ulcer, and aninism conclude what is undoubtedly a most complete and comprehensive survey of the pathology of tropical diseases. The book is well got up and printed and it should be available to all whose work lies in the field of tropical medicine.

KNEE-JOINT INJURIES

Injuries of the Knee Joint. By I. S. Smillie, M.B., F.R.C.S.E., F.R.F.P.S. (Pp. 320, illustrated 35s., plus 7d. postage.) Edinburgh: E. and S. Livingston, 1946.

Mr Smillie had the opportunity of treating a vast number of deranged knees among civilian and military patients in an E.M.S. hospital throughout the recent war, and as a consequence has written a monograph covering the whole field of knee joint injuries. In this he has been aided by enterprising publishers. Nevertheless, impressive book production does not excuse the defects which soon become apparent.

It seems a pity that the author did not hold his hand a little longer so as to have presented a proper statistical analysis of his results. He might even have combined with a number of surgeons who in the Services have also done good work. If thus he had produced a symposium limited to internal derangements of the knee we should have had a modest book of lasting value. Instead one finds a copious, unbalanced and incomplete review, greatly padded with material relating to every conceivable sort of injury to the knee-joint. A book for experienced surgeons has been combined with one for novices. All of which has recently been done concisely and with greater authority elsewhere.

One of the contributions draws attention to the filling up by fibrous tissue of the peripheral defects left when a meniscus is removed. This was recognized before, but it is not "regeneration." The replacement is not cartilaginous nor does it reproduce the shape or appearance of a normal meniscus. The degree to which meniscal shape is restored to the fibrous structure certainly is interesting and its different appearance is sufficient to distinguish it from an incompletely removed meniscus. Of all his cases 65% of the menisci removed were medial and the rest lateral—a rather higher proportion of the latter than usually expected. Differentiation of the types of tear and of cystic degeneration in each would have been of interest. Mr Smillie has designed a very useful set of special cartilage knives but he overlooks their forerunner in the Lowe-Breck knife.

In the discussion of ligament injuries no number of cases treated are given. The author states that the circumstances demanding operation for cruciate damage are rare. He has nevertheless found 17 patients with anterior cruciate loss upon whom to carry out a procedure of dubious value—namely, the transposition of the peripheral portion of a medial meniscus after detaching it posteriorly and passing the structure along the line of the old ligament through the lateral femoral condyle. The report on end results is incomplete and so unsatisfactory. In discussing fracture of the patella statistics are again lacking but the author does well in dealing with it as one only of the possible lesions in injuries to the extensor apparatus. Like most writers upon the patella he does, however, tend to regard its function too much in terms of its influence upon the tibia and not at all in relation to its mechanical effect upon the femoral condyles when the foot is fixed upon the ground—the commonest circumstance in which the quadriceps apparatus is ruptured. His treatment of this fracture is reasonably conservative. In connexion with operation for recurrent dislocations of the patella no acknowledgment is given to the work of Goldthwaite or of Hauser. The rest of the book deals with the remaining intra-articular fractures and with some injuries further afield which may involve the knee joint in some form of disability. A perfectly illustrated anterior displacement of femoral condyles in Fig. 270 is described as a backward displacement.

The book starts and finishes with emphasis on an interpretation of quadriceps muscle function, based upon the writings of another surgeon in which it is implied that the vastus medialis section only comes into action to complete the last 15° of knee extension the earlier range being the function of the rest of the quadriceps. Neither of these surgeons is an anatomist or a physiologist, and in the absence of carefully checked scientific data we will not genuflect to such authority.

HOMANS'S TEXTBOOK OF SURGERY

A Textbook of Surgery. By John H. Homans, M.D. Sixth edition. (Pp. 1,278, 530 illustrations, \$3.00 or 4s.) Springfield: Charles C. Thomas; London: Baillière Tindall and Cox, 1945.

First published in 1931 this textbook by the beginning of 1940 had reached a fifth edition, and a sixth has just appeared, so that the war years intervene between the last two editions. In those grim years there have been some profound modifications in surgical practice chiefly because of experience gained in the treatment of wounds and infections after the introduction of the sulphonamides and penicillin. This new edition embodies such experience and brings the work well up to date in all directions. As an example of this, in the section on the brain there is a paragraph on the use of fibrin foam and fibrin film in neurosurgery. The preface calls this a war edition, but it might with equal accuracy be described as postwar, since we have here an excellent account of the practice of surgery in the postwar period of to-day.

Dr Homans is now emeritus professor of clinical surgery at Harvard and the names of the original contributors no longer appear on the title page of the book, otherwise its format remains as in previous editions, and we are pleased to notice the retention of the historical approach to the various chapters. We would repeat what we said of the fifth edition, that no teacher should be without a copy of the book. Likewise the student, whether he be approaching his qualifying examination in surgery or more experienced and revising in preparation for a higher examination, should find it most valuable. Neither unwieldy nor too concise, the book is readable and can be thoroughly recommended.

PSYCHOANALYTIC THERAPY

Psychoanalytic Therapy: Principles and Application. By Franz Alexander, M.D., and Thomas Morton French, M.D., and Staff Members of the Institute for Psychoanalysis, Chicago. (Pp. 353, \$5.00.) New York: The Ronald Press Company.

This is an important book. It is based on seven years' work by the staff of the Institute for Psychoanalysis of Chicago in a concerted effort both to define those basic principles which make possible a shorter and more efficient means of psychotherapy and whenever possible to develop specific techniques of treatment. This represents a real break-away—not so much from psychoanalytic doctrine as from its technique and practice.

for several cases are quoted in which successful results have been achieved by twenty or fewer interviews. In many cases these interviews were spread over a year or more; but it is not the total length of treatment which is of such practical importance as its cost and time consumption for the patient. It is clear that only those who have had experience of the more rigid psychoanalytic techniques and a real knowledge of the theories and observations of Freud and his pupils could successfully employ these shortened methods. Many psychotherapists are finding that, given this knowledge and experience on the part of the therapist, propositions as to the likely cause of his troubles and the nature of his faulty reactions to life may be put with good effect before the intelligent patient for his acceptance or rejection. This allows for a much less passive attitude on the part of the patient, a greater degree of give and take between the participants in the treatment, and therefore more opportunity for synthesis as well as analysis. Obviously, since psychotherapy is so individualistic, great flexibility of method is necessary as between one patient and another, but the experienced therapist ought to be able to make a relatively quick appraisal of each patient's personality and problems and thereon plan a course of treatment appropriate to his needs. In this way it may be possible to deal with the vast numbers of mild incipient cases which are so much commoner—and more important—than the severe chronic cases. Also psychotherapy may be brought to bear more directly on the many psychosomatic conditions which have come to be regarded as due to emotional stress but for which psychiatrists have done all too little. The description of a case of peptic ulcer proved by x rays, and another of asthma shown to be allergic to certain foods, are of great interest in this respect.

A close study of this book will repay a wide circle of readers, both in encouraging those who are seeking to reduce the cost and time factors of psychotherapy and in persuading others that psychotherapy is less impracticable for their patients than they may have at one time thought.

EXPERIMENTAL CATATONIA

Experimental Catatonia. A General Reaction-Form of the Central Nervous System and Its Implications for Human Pathology. By Herman Hollend De Jong, M.D. (Pp. 225; illustrated, \$4.00 or 22s.) Baltimore: Williams and Wilkins Company; London: Baillière, Tindall and Cox. 1945.

In this monograph Prof. De Jong has collected the results of his classical work, which began in Amsterdam nearly a quarter of a century ago and has been continued in America since his escape from Holland in 1940. The author's previous monograph, written with H. Baruk in 1930, dealt with experimental catatonia produced by bulbocapnine, but the present volume describes experiments on catatonia brought about by other chemical and physical methods, and includes the application of some of this work to man. The first seven chapters give detailed account of animal experiments with bulbocapnine, scoline, asphyxia, centrifuging, electric stimulation, and by teration in metabolism; the next six deal with catatonia in man, with special reference to the effects of urine extracts, histamine, and the cephalin-cholesterol flocculation test.

The book has great value for all experimental psychiatrists, especially as Prof. De Jong says "the goal has not been to contribute to any particular trend of thought, but only to seek the truth."

Notes on Books

Die Verteilung der Sulfonamide im Organismus, by PAUL EGGER (Basle: Benno Schwabe and Co., 8 Swiss francs), is concerned with a study of the fate in the body of three sulphonamides, evidently those most popular in Switzerland. These are "cibazol," which is well known to us as sulphathiazole; "irgafen," made by Geigy, which is dimethylbenzoyl-sulphanilamide; and finally "elkosin," another Ciba product, sulphanilamido-dimethylpyrimidine, which is a relative of sulphamezathine. Much of the information in the monograph is similar to that already acquired for other sulphonamides. The author has, however, examined the amount of sulphonamide present in a large number of organs obtained at operation or from recently dead subjects. He has made the interesting observation that the concentration in the skin is high, being about equal to, or, for sulphathiazole, greater than, the concentration in the blood. No wonder these substances cause skin rashes, and that sulphathiazole is particularly prone to do so. Probably the high concentration in the skin is due to the fact that they are being excreted in part in the sweat.

La Médecine dans l'Ancien Pérou, by RAOUL D'HARCOURT (Paris: Librairie Maloine), is a summary of works by old Spanish authors and archaeological and anthropological researches into the maladies of the Indians of ancient Peru. Since writing was unknown to these people the facts related have had to depend on tradition and on primitive graphs, made on pottery and the glaze of vases, dug from the sands of the Peruvian coast. Medicine was in the hands of priest healers, who were herbalists and had a wide range of remedies. They did not hesitate to do such operations as cranial surgery, judging by the illustrations. Amputated stumps in mummies show evidence of having been neatly sutured. This book deals with a civilization which preceded the establishment of the Inca kingdom in the 12th century B.C.

The W. B. Saunders Company of Philadelphia and London have republished in book form the Chicago Number, dated January, 1946, of the *Medical Clinics of North America*, containing the Symposium on Pediatrics. In a brief foreword Dr. Stanley Gibson introduces these discussions of modern problems in disease in childhood and the medical care of children, and himself contributes one of the eighteen papers on varied subjects in his specialty. At the end of the symposium there are two papers outside the range of paediatrics: one on Dupuytren's contracture and the other on control of gonorrhoea. Six numbers of the *Medical Clinics of North America* are published in the year; they are sold by annual subscription at 55s. in paper binding or 75s. in cloth binding.

Preparations and Appliances

COLOUR INDEX NOMOGRAM

Dr. B. J. FREEDMAN, M.R.C.P., writes from St. Giles' Hospital, Camberwell, S.E.5:

The calculation of the colour index of the erythrocytes is a little daily task of no great difficulty that presents itself on innumerable occasions to pathologists and laboratory technicians. As with any other repetitive task, a labour-saving device is welcome. The diagram shows a nomogram that I have

devised for its rapid determination. A ruler is placed on the appropriate points on the red cell and haemoglobin scales, and the point of intersection of the ruler with the middle scale gives a direct reading of the colour index. The straight edge of a transparent strip of x-ray film is better than a ruler as it renders interpolation easier.

Those who wish to construct their own nomograms may do so by drawing the two parallel vertical scales about 5 in. (12.5 cm.) apart, 1 in. (2.5 cm.) on the scale representing 1 million R.B.C. and 20% haemoglobin respectively. The oblique scale is made by joining the two zeros, and is calibrated by laying a ruler across the 5-million mark and various haemoglobin percentages.

For bench use the whole is best drawn on card and varnished.

SATURDAY JUNE 1 1946

ALUMINIUM THERAPY OF SILICOSIS

It was in 1937 that Denny, a metallurgical engineer, Robson, chief surgeon to the McIntyre Porcupine Gold Mine at Schumacher, Ontario, and Irwin,¹ associate professor in the Department of Medical Research at Toronto, under Sir Frederick Banting, reported that in dusting experiments they could produce typical nodular silicosis in rabbits, but that if the quartz dust was mixed with aluminium dust of particle size less than 5μ , the proportion of aluminium in the mixture being less than 1%, nodular fibrosis did not occur. In 1939² they further showed that the metallic aluminium on being converted into hydrated alumina reduced the toxicity of quartz in tissues by flocculation, partly by absorbing silica from solution, but chiefly by coating the quartz particle with an insoluble and impermeable coating which is gelatinous hydrated alumina. This, on drying, forms the crystalline alpha aluminium monohydrate ($\text{Al}_2\text{O}_3 \cdot \text{H}_2\text{O}$), which stains red with aurine. They also exposed eight rabbits to an atmosphere containing freshly ground finely particulate aluminium powder in a concentration averaging 7,000 particles per ml. 12 hours daily for 14 months. After cessation of the dust exposure some of the animals were observed for a further seven months. Chemical assays of the lungs showed them to contain from 270 to 1,200 mg. of aluminium per 100 g. of dried tissue. During their lifetime these animals gained normally in weight, and from the appearance and texture of their fur and general behaviour there was no evidence of any harmful effect. At necropsy there was no evidence of fibrosis of the lungs, the only abnormality being aggregates of dust cells containing irregularly shaped opaque particles. In repeated experiments in rats Belt and King,³ however, found that the particles were treated as foreign bodies in the lungs, forming small concretions with fibrous tissue round them. Nevertheless in 1944 Leroy Gardner⁴ and his colleagues confirmed with experimental evidence beyond question that aluminium and aluminium hydrate (XH-1010), probably in amorphous state, specifically inhibit fibrous reaction to quartz, and that their administration will prevent progression of silicotic lesions and cause retrogression in immature tissue responses.

Evidence on the effect of aluminium in pneumoconiosis also comes from the recent report of the experimental studies on chronic pulmonary disease in the South Wales

coal-mines published by the Medical Research Council.⁵ These studies revealed that the most severe reactions in lungs result from quartz, but that the pathogenicity of this substance is reduced by clean coal and is practically abolished by shale. There is little doubt that the production of silicosis depends on the solubility of silica, and it is proved that quartz particles coated with iron oxide⁶ or alumina are less soluble than those which are not. King found that the shales depressed the solubility of the quartz by releasing aluminium from their aluminous components to form a protective covering over the quartz particles which could be stained with aurine. It was also demonstrated that mineral dusts containing higher proportions of aluminous components were more inert, even after being in the lungs for a long time; this is well shown by the fact that the shales are probably less dangerous to health than the sandstones. King also explained the pathogenicity of anthracite coal, which *in vitro* depresses markedly the solubility of quartz, by suggesting that the aluminous and siliceous components of steam and bituminous coal must be much more closely bound to the coal substance than is the case with anthracite.

Before applying the method for the prevention of silicosis in man it is essential to show that metallic aluminium is without harmful effects. In 1936 the Medical Research Council,⁷ after reviewing the findings in a group of fifty workers exposed for many years to alumina, were unable to find any evidence that the inhalation of alumina dust had caused pulmonary fibrosis, while Hunter, Milton, Perry, and Thompson⁸ were unable to find disease in the lung in 92 duralumin propeller grinders. Crombie, Blaisdell, and MacPherson⁹ investigated 125 employees engaged in making aluminium powder by a stamping process: they had been on this work for periods ranging from six to twenty-three years, and they were submitted to x-ray examination each year. Aluminium powder did not cause lung damage, nor did it favour the development of tuberculosis or any other condition. During the war of 1939-45, however, many papers from Germany described a condition of pulmonary fibrosis with frequent spontaneous pneumothoraces in workers making alumina powder.¹⁰⁻¹² These papers remain an enigma. It must be pointed out, however, that there are many differences in aluminium powders. Denny, Robson, and Irwin's powder is black; it contains 95% metallic aluminium, and its particle size is under 5μ , accounting for its black colour. Stamped aluminium powder is coated with stearine, while blown aluminium powder is coated with aluminium oxide. It is possible, therefore, that aluminium may not be completely harmless, and its use should be allowed only under the supervision of expert observers.

At the Porcupine Mine Denny, Robson, and Irwin have treated miners by blowing with compressed air metallic aluminium dust from small canisters into the rooms where

the men change for about 20 minutes before they go down the mine, and after they come up. Their results are not yet published, but miners returning to this country are enthusiastic about this method of preventing silicosis. Crombie, Blaisdell, and MacPherson⁸ treated men in the same way but prepared the aluminium from a mill. By this method there is a small explosive risk if the motor is close to the mill, aluminium dust forming an explosive mixture if the concentration is more than 0.02 oz. per cubic foot (0.02 g. per litre). Thirty-four men with diagnosed silicosis were treated by daily inhalations beginning with 5 minutes and gradually increasing to 30 minutes. Some men received 300 treatments, the majority about 200. Out of the 34 cases studied, 19 showed clinical improvement with diminution of the dyspnoea, cough, pain in the chest, and fatigue, though they continued to work as miners; the remaining 15 cases remained stationary. Progress of the disease was assessed by means of respiratory function tests, repeated at three-monthly intervals. Bamberger¹⁴ also treated a group of non-ferrous metal miners with both metallic aluminium and hydrated alumina (XH-1010), and claimed that about one-third in each group showed symptomatic improvement though there was no significant change in exercise tolerance or vital capacity in any case. Aluminium dust cannot be regarded as a cure for silicosis, but these results suggest that it may prevent the development of human silicosis and may possibly arrest the progress of the disease when it is established.

These promising developments have been marred by two recent happenings. Denny and Robson¹⁵ have taken out a patent for this method of treatment in the United States and Canada, and created a company with the McIntyre Porcupine Mines, Ltd., known as McIntyre Research, Ltd., while in Australia and Tasmania laws have been passed to compel employers to install this method of treatment in their change houses. In this country the law does not allow the patenting of therapeutic methods, and British search workers are therefore free to investigate, assess, and develop the method. There is even an obligation to carry on investigations when restrictive influences are at work elsewhere. It is also appropriate to draw attention to the recent report of the Council on Industrial Health of the American Medical Association,¹⁶ which states that the administration of high concentrations of amorphous hydrated alumina unfavourably influences resistance to tuberculosis; and recommends that the general application of aluminium therapy in industry be delayed until adequately and impartially controlled clinical observation demonstrates its effectiveness in preventing or alleviating silicosis in man. It is evident that the real way to prevent silicosis is to prevent siliceous dust, and engineers must be encouraged to attain this end. Their achievements with wet drilling up to the present have been very great, and there seems no reason to doubt that within the next century their efforts will be rewarded with complete success. In the meantime mining must go on, and so must research into all possible methods likely to prevent or arrest silicosis in those engaged in the industry.

DIET AND INCOME

On another page Dr. E. R. Bransby gives the results of a dietary survey, made in 1941 by the Ministry of Health, of a number of working-class families chosen at random from various parts of the country. This period, it may be remembered, was one of transition from the days of pre-war plenty to wartime austerity and food rationing. By 1941 there had been considerable changes in the economic condition of the country. Food prices had risen by about 25% and wages by about 40% above 1938 levels. The present-day figures are approximately 22% and 50% respectively, though the former figure is really fictitious, as food prices have been kept low by the Ministry of Food subsidies, which, of course, ultimately come out of the taxpayer's pocket. The extra he would pay for food owing to the rise in the cost of living is taken out of his wage or salary. In 1941 the milk-in-schools scheme and the national milk scheme were in operation, but not the vitamin schemes for expectant mothers and babies, and the school meals service was operating only to a very limited extent. The bulk of the bread consumed was made from 75% extraction flour.

The survey confirms much that was already known to the social worker and the general practitioner familiar with the conditions in working-class families. It is not surprising to read that those families with an income sufficient to spend 13s. a week per head on food averaged only one child. Based on the present-day cost of living this is not an excessive sum to provide an adequate level of nutrition without monotony. On the other hand the families with four to five children spent less than 5s. a week per head on food—a totally inadequate amount judged by any standards. The consumption of most foods, and particularly the protective ones, was notably greater among the families with few children than among the families with several children. Both groups ate approximately the same amount of potatoes, margarine, oatmeal, fats, and sugar—all foods which are cheap or rationed. These are the energy-producing foods. For the protective foods the difference in consumption in the two types of family was considerable. The intake of meat, milk, eggs, vegetables and fruit was much greater among the families with higher than among those with a lower food expenditure per head. On an average the consumption of these foodstuffs was 450% more in the former group than in the latter. For fruit and vegetables the figure was 1,700% higher.

Judged by the League of Nations standards of minimum requirements, and by costs calculated in 1942 by Magee and George, the intake of all nutrients, except protein, was inadequate among those families spending less than 9s. per head a week on food. Most families with more than two children spent less than this a week. Particularly deficient were the intakes of calcium, vitamin A, and vitamin C. Magee and George, at the request of the Ministry of Health Advisory Committee on Nutrition, compiled figures to show that the standards for an adequate diet, as recommended by the League of Nations Commission, cannot be satisfied if less than 9s. per head is spent on food. This figure is for adults and older children; in

¹⁴ *Industr. Med.*, 1945, 47, 185.

¹⁵ Robson, W. D., *Trans. Canad. Mining Inst.*, 1944, 47, 172.

¹⁶ *J. Amer. med. Ass.*, 1946, 130, 1223.

ranges from 7s. 6d. to 4s. for younger children and infants. These figures presuppose some knowledge of nutrition, which is unfortunately possessed by few housewives, and a wise choice of "points" and unrationed foods. The Beveridge report recognized this and wrote off 1s. 6d. per person per week for wastage due to lack of nutritional knowledge. This brings the weekly food budget up to 10s. 6d. for adults and older children, 9s. for younger children, and 5s. 6d. for infants. These are the minimal figures based on recommendations of the Ministry of Health.

A further interesting fact noted in Bransby's survey is that as expenditure on food increases, the number of cooked meals eaten each day increases; as the family income falls more of the "bread and spread" type of meal is eaten. Apart from being a poor source of the protective elements, the latter may actually lead to a decreased food consumption through monotony and lack of appetite and interest in food. We all know how the sight and smell of palatable cooked food stimulate the desire to eat. Man cannot live by calories and vitamins alone. It is true, as McCance and Widdowson have shown recently, that it is possible to live for a limited period on a diet of bread, potatoes, and vegetables. Whether it is possible to thrive on such a diet is another matter. The volunteers in McCance and Widdowson's experiments were eating only an experimental diet for a limited period; they knew that if necessary they could resume their normal accustomed diet; and, what is most important, they were healthy adults and not children or invalids, so it was not proved that such a diet provided for growth and repair. Further, the extraction rate of the flour in the bread eaten was 92%, not 75%, the figure for white flour eaten before 1942. McCance and Widdowson recognize that the results might have been different if their volunteers had eaten bread made from low-extraction flour.

The survey demonstrates only too well that any increase in the number of children beyond two in the average working-class family leads to a lowering of the nutritional standard of all its members. It is futile for the Minister of Health to suppose that health can be bought with his new Bill when many of those who will have to pay for it are spending less on food than the minimum recommended by experts in his own Department. The masses need food and houses before health centres. The level of nutrition in many families could be improved by increasing the income-tax allowance for children, providing free school meals, and payment of part of the proposed children's family allowance in the form of vouchers exchangeable for protective foods.

PLASTICS IN SURGERY

Surgery has often benefited from methods and materials elaborated in other branches of applied science. Blaine¹ has recently extended his earlier observations² on the behaviour of plastic materials in the tissues of experimental animals, and Small and Graham³ have been using plastics for the closure of skull defects.

It is convenient to recognize two kinds of plastics, protein and non-protein; the former are absorbed by animal tissues, while the latter are not. Blaine found that casein plastic, one of the protein group, could be machined to make screws, plates, blocks, and nails. Though less strong than the metals, when fresh it has a tensile strength similar to that of bone, but after a few weeks in the warm and moist tissues of the animal it softens and loses its tensile strength. This loss will have to be overcome if the material is to be used in man to support any considerable and prolonged strain. Casein plastic has certain advantages for use in bone surgery. It may be autoclaved for twenty minutes at 15 lb. (6.8 kg.) pressure and 120° C., provided it is dried and cooled afterwards. It is ultimately completely absorbed and replaced by bone. It produces no unfavourable tissue reaction *in vivo*, and *in vitro* it does not inhibit the growth of a tissue culture.

A non-protein plastic which Blaine investigated is methyl methacrylate, better known as acrylic resin or "perspex." As Beck and others⁴ had previously shown, perspex resembled "nylon" in causing no tissue reaction (this is not true of all non-protein plastics), and it did not inhibit the growth of a tissue culture. Drury and others⁵ found it highly resistant to bacterial growth on its surface, and its interior remains sterile after many months of external contamination. Blaine concludes from animal experiment, however, that it has no outstanding advantages over the metals, and it has a lower tensile strength. Small and Graham state that methyl methacrylate is suitable for the closure of skull defects in man. They employed a method similar to that devised by Shelden and others⁶ to provide a transparent calvarial window for direct observation of the brain in monkeys.

Methyl methacrylate is supplied as a clear liquid monomer and as a polymer in powder form. When mixed they yield a soft mass which, on heating, undergoes irreversible polymerization to produce a light, tough resin, transparent and radiotranslucent, of which the final shape can be defined by pressure in a mould during polymerization. The elaboration of the plate for inlay requires several hours of laboratory work, and consequently the impression is taken at a first operation, and the perspex plate inlaid at a second. To overcome the disadvantage of a two-stage operative procedure, which does not lessen the value of a plastic in oral or ophthalmic surgery but is a considerable handicap in surgery's other branches, Blaine has reduced to twenty minutes the time necessary to prepare the final plate for inlay. In one method, the plastic, fully polymerized and heated to 130° C., is moulded to a plaster model, under aseptic conditions in a special press. In Blaine's second method a dough of monomer (with benzoin as catalyst) and polymer is applied directly to the bone defect, and polymerized *in situ* by ultraviolet light, under which the hardening process takes place in only fifteen minutes. If this last method proves applicable to man, perspex may be used to repair incomplete defects in the facial bones, and perhaps also in arthrodesis.

PLAN FOR SURREY HOSPITALS

The voluntary and municipal hospitals of Surrey, with the county borough of Croydon, set up a joint divisional council in 1941, and while Government schemes were being laid, the council produced a plan for co-ordinating and extending the hospital services in the county. The plan has been framed on the assumption that "as free a

choice as is practicable by the citizen of his medical adviser will continue and the voluntary hospitals will not only be permitted but encouraged to function in the future." The general scheme, for which the late Sir Laurence Halsey, chairman of the council, was largely responsible, is based on the provision of four types of hospitals—key hospitals (one or more of the London teaching or special hospitals), and district, local, and special hospitals, these last including mental hospitals, tuberculosis sanatoria, and hospitals for infectious diseases. It is proposed that the county should be divided into seven sections, each with one or more district hospitals equipped with means for treating on modern lines both in-patients and out-patients. The target for the district and local hospitals on the basis of six beds per 1,000 of population calls for 9,078 beds, whereas the present provision is only 5,259. Other targets are adopted for sanatoria and special hospitals.

According to the scheme the key hospitals are to be responsible for major plastic and thoracic surgery, neurosurgery, and radium and deep x-ray treatment. The district hospitals would cover general medicine and surgery, children's diseases, ear-nose-and-throat cases, fractures and orthopaedic cases, and various other categories; each of them should also have an out-patient ophthalmological department. Major operative work should be concentrated in certain district or special hospitals, and radiotherapy should be undertaken, when required, in collaboration with the key or special district hospitals. Each district hospital should also have an obstetric unit under the control of a senior obstetrician and gynaecologist, with other units associated with local hospitals and having local obstetrical staff. An out-patient department for rheumatism is also called for in all district hospitals. It is thought essential for radiotherapy to be practised in special centres, but there should be no segregation of cancer cases, though patients beyond active treatment and who cannot be cared for at home should be kept in special wards. Local hospitals should all be prepared to deal with emergency cases and arrange for regular attendance of consulting staff.

Whatever the fate of the hospitals of Surrey in a scheme embracing a larger region, the careful work put into these proposals will be of value, perhaps beyond the county as well as within it.

THE INSECTICIDE GAMMEXANE

The publicity given to D.D.T. somewhat overshadowed the subsequent British discovery of another synthetic insecticide of perhaps equal potentialities—"gammexane," an account of which was given by Slade last year.¹ Early in 1942 the biological field workers of Imperial Chemical Industries were looking for new chemicals to control the turnip flea-beetle. They found that certain samples of benzene hexachloride (or, more properly, hexachlor-cyclohexane) were very effective. The material was called "666" from the chemical formula $C_6H_6Cl_6$, and this name was used in early reports and commercial preparations. The compound hexachlor-cyclohexane exists in a number of isomers differing in the spatial configuration of the atoms in the molecule. When these had been isolated and tested separately, it was found that practically all the insecticidal action of the material was due to the gamma isomer. Hence the name gammexane.

Pure gammexane is a white crystalline substance melting at 112° C. It has a low vapour pressure (0.14 mm. Hg at 40° C.), but this is appreciable and means that thin films

are less permanent than D.D.T., which is practically non-volatile.² Gammexane is virtually insoluble in water but dissolves to different degrees in various organic liquids. Like D.D.T. it is chemically stable under most normal conditions. Gammexane is toxic to insects when eaten or merely by contact with the insect's cuticle; the vapour is also toxic. The insecticidal action is exceedingly high, since according to the data available the lethal dose to various insects is lower than that of D.D.T.—e.g., one-twentieth the dose to lice,³ one-fifteenth the dose to grain weevils,¹ one-tenth the dose to bed bugs,² one-ninth or one-third to houseflies,^{4,5} and one-half to the mosquito *Aedes aegypti*.⁵ Gammexane has also been shown to be highly toxic to ticks of sheep⁷ and cattle.⁸

Cameron⁶ and Taylor¹ have investigated the toxicity of gammexane to mammals. Like D.D.T., gammexane is much less toxic as a dry powder or as an aqueous suspension than when in solution. The pure compound is more acutely toxic than D.D.T., since the lethal doses to various animals are one-half to one-fifth the corresponding doses of D.D.T. The chronic toxicity of repeated doses, however, is about the same or possibly rather less than that of D.D.T. The characteristic warning signs of intoxication by D.D.T. are unfortunately absent with gammexane. In chronic intoxication, however, there are lethargy, anorexia, and loss of weight. Prof. Cameron concludes that gammexane "is of relatively low toxicity when applied to the skin or administered orally in single doses. Fairly large doses given repeatedly may be tolerated." It seems to be clear that the substance is safe to use in ordinary insecticidal preparations.

At present only one preparation of gammexane is commercially available. This is the powder known as 666 Dust Grade DO34, which contains about 0.6% gammexane, together with other isomers and some impurities, diluted with kaolin. The powder in bulk has an appreciable musty smell which becomes rather pungent and irritating when it is blown into the air. This dust has been used with success against insects (houseflies, crickets) breeding in refuse dumps, which are often a serious nuisance to neighbouring residents. Gammexane is very toxic to lice, fleas, bed bugs, cockroaches, and other medical and domestic insect pests. The characteristic odour already referred to, however, is regarded as objectionable by many people, and this limits the use of the Grade DO34 preparation. It is understood that investigations are proceeding to develop other formulations which are without this disadvantage.

The Albert Gold Medal of the Royal Society of Arts, which was struck in memory of the Prince Consort in 1864, has been conferred by the Society this year on Sir Alexander Fleming and Sir Howard Florey, as a joint award, for their services in the discovery and development of penicillin.

The National Association for the Prevention of Tuberculosis proposes to hold in London, in midsummer, 1947, a conference dealing with tuberculosis in all its aspects. This conference will probably last three days, and invitations will be sent to representatives from the British Commonwealth and Empire. Visitors are expected also from the United States and from some European countries, and this direct exchange of ideas should promote a closer contact between various countries and the local health authorities responsible for tuberculosis in Britain.

THE SCIENTIFIC METHOD IN CLINICAL MEDICINE

BY

W. D. CRUIKSHANK, M.D., F.R.C.S. Ed., F.A.C.S.

Recently Professor of Surgery, Royal College of Medicine Baghdad

The writer of this article, immediately upon graduation, was sent to an isolated tent hospital in the Rocky Mountains. This hospital had no laboratory beyond what he made for himself. In his inexperience he found the clinical responsibility very heavy, but it never occurred to him that he had isolated himself from the scientific practice of medicine. Among many cases studied in that lonely hospital the treatment of one stands out as the most satisfying scientific success of what has since been a long professional life.

This writer, therefore, has been surprised frequently to hear physicians posted to outlying stations complain that in these stations they could not practise scientific medicine. He has investigated many such complaints, and in each case he believes that he has discerned a failure to understand the essence of the scientific method in clinical medicine. He has found that, in the minds of many, scientific medicine is confused with the ancillary sciences. He finds many physicians unaware that clinical medicine possesses its own scientific method and that this scientific method may be successfully practised independently of the ancillary sciences.

In a teaching school the ancillary sciences—chemistry, bacteriology, radiology, etc.—are particularly important. They provide the student with objective confirmation of the truths arrived at by purely clinical science. This should not make the student dependent upon them. Rather should it make him increasingly independent of them. When the student finds his own rational and objective findings constantly confirmed by the ancillary sciences he should then become more confident in his own science and less dependent upon the science of others. In a school training physicians, the chief function of the ancillary sciences should be to train the clinical scientists in their medical practice to be largely independent of the ancillary sciences.

Technique of Clinical Science

To all the sciences one method of procedure is common. This method is: (1) the collection of facts, (2) the selection of those facts that are significant, (3) the orderly arrangement of these facts in time sequence, (4) the contemplation of these facts until causal relationship becomes apparent, (5) the checking or control of the newly discovered causal relationship until its truth is established beyond question.

True clinical science follows exactly this technique. Each patient becomes the subject of an original research to discover previously unknown truth. In the interest of the patient it is essential that this truth (the diagnosis) should be established scientifically beyond the possibility of doubt. In clinical medicine this is accomplished by the scientific method.

(1) *The Collection of Facts*—The means by which genuine facts relative to a patient's complaint are acquired is an art in itself. The art requires gentleness, diplomacy, a sympathetic bearing, and often great patience. To cross-check and verify the truthfulness of the facts obtained one needs to know something of what the lawyers call the theory of evidence. It is seldom that the patient is a scientist, but the true physician must always be a scientist searching for truth. The responsibility for the truthfulness of the facts accepted rests not with the emotional patient but with the objective scientist. To call a patient a liar is generally an error of art, but to mistake fiction for fact is a scientific error. The accumulation of the facts requires tact, experience, judgment, and profound knowledge of human nature. This art can no more be learned from a book or a lecture than can that of playing the violin. Only by serious and persistent practice can the art be perfected.

(2) *The Selection of Significant Facts*—This also is an art that improves with experience. The beginner wisely includes all facts that might possibly have some significance. As experience increases the physician becomes more expert at recognizing what is significant. The facts seized upon, although fewer in number, are more significant.

(3) *The Arrangement in Time Sequence*—The facts as acquired are seldom in correct time sequence. They are usually procured in reverse time sequence. To demonstrate cause and effect they must be arranged in normal time sequence. This implies record with exact dates. Great scientific discoveries have depended entirely upon the fact that exact records had been kept with dates.

(4) *Contemplation for Causal Relationship*—One must study the facts now recorded in orderly time sequence. This is the essence of the scientific method. After a long life of clinical experience I am more and more impressed by the causal relationship that becomes apparent when clinical facts are carefully recorded in correct time sequence. When Darwin published his *Origin of Species*—probably the greatest scientific contribution of the nineteenth century—he stated that he believed he had truly followed the scientific method, because he had contemplated his facts for eighteen years before presuming to publish his hypothesis. The practical physician must contemplate more rapidly, but it has always been significant to me that the best physicians whom I have known seldom committed themselves to diagnosis on the first day. Colleagues criticized them for their slowness, but patients flocked to them because they were so frequently right.

In clinical cases it is seldom that such contemplation does not reveal causal relationship. We have now made a clinical history, and almost inevitably this will suggest causal relationship. In scientific language the latter is a hypothesis. Clinically we call it a working diagnosis.

(5) *The Proving of the Hypothesis*—The first and by far the best method of check or control is a thorough physical examination. The physician to be scientific, must train himself until he is familiar with the normal findings of health. Independently of the working hypothesis, and as objectively as possible, the patient is thoroughly examined from head to foot to find what variations there are from the familiar normal. Such examination, of course, is worthless unless the physician be familiar by practice with the normal. Here again we have an art that cannot be learned from a book. Like all the arts it can be perfected only by persistent and patient practice.

Certain variations will almost always be discovered—variations that indicate certain pathology. If this pathology conform to the original hypothesis (it will do so nineteen times out of twenty) then the working diagnosis has been reasonably well established. Our original hypothesis by an entirely independent and objective method of approach has been controlled scientifically and established as truth. By purely scientific method a hitherto unknown truth, the diagnosis, has been discovered and confirmed.

Further Control of the Reasonably Confirmed Hypothesis—Our scientific physician will then wish even more accurately to prove the truth of his diagnosis. As a practising physician he will do this by what is known in clinical science as the therapeutic test. For instance if the confirmed hypothesis be "pleurisy with effusion" an aspiration will almost certainly demonstrate the absolute truthfulness of the original hypothesis. At the same time such procedure brings relief to the patient and thereby establishes the clinical scientist as also a beneficent physician.

Relation of the Laboratory to Clinical Medicine

We have now described clinical medicine as it has been practised by scientific physicians ever since the scientific method was demonstrated by Hippocrates. This or a similar scientific method is practised by our best physicians everywhere. It is this method that distinguishes them from the quacks and impostors. When we subscribe to the Hippocratic Oath we bind ourselves to the Hippocratic tradition. Only those who follow in this scientific tradition are worthy disciples of Hippocrates.

What, then, of our scientific laboratories? We indicated above their essential place in a teaching school. The disciple of Hippocrates is always at school. The art is so long and time so short and judgment so difficult that the Reaper inevitably overtakes the Disciple before the discipline has been perfected. The discipline is infinite and always stretches out in advance of the disciple. The scientific laboratories are places where specialized scientists are willing to assist the clinical

scientist to discover additional and possibly very significant facts that may elaborate or perfect a picture of disease already built up by the clinical scientist. The clinical scientific method readily elucidates hundreds of significant facts. Among these cause and effect is usually evident; diagnosis becomes obvious and in the great majority of cases is ultimately thoroughly established by the therapeutic test. In an occasional case some causal relationship may be obscure or an effect may seem to be disproportionate to its apparent cause. In this occasional and so-called "difficult case" the specialized laboratory may be of inestimable value in supplying an additional and very significant fact not elicited clinically. This is the true function of the laboratory in clinical medicine.

It is not the function of the laboratory to make a diagnosis. The laboratory findings are liable to human error just like the patient's statements, and must be subjected to rigid control. Even when entirely correct the laboratory finding may be of no significance in relation to the patient's complaint. I have occasionally seen a non-significant fact, quite correctly discovered by a laboratory, acted upon disastrously. The making of a diagnosis and the control of clinical treatment are functions and responsibilities of the physician. Overwhelming disaster has marked the assumption of these responsibilities by the non-clinical scientist.

Furthermore, the overworking of our purely scientific laboratories through entirely unnecessary routine and innumerable requests for diagnoses such as every physician should make for himself is deplorable also because the laboratory's true function is embarrassed and the physician's clinical and scientific ability remains embryonic. We see so-called physicians abandoning entirely those arts that constitute the veritable basis of scientific medicine. They deliver themselves and their patient entirely into the hands of non-clinical scientists. They degrade themselves into becoming mere agents for the laboratories. The only ability they cultivate is that of reading laboratory reports. Since they have all learned to read, the discipline for them has become easy.

A shrewd observer points out the irony of a situation so organized that only two men ever examine the sick patient—the radiologist in the dark and the pathologist after the patient is dead. The result is inevitably disastrous to "the Art respected by all men in all times."

Such circumstances I believe to be the essential cause of that deterioration in clinical ability which is now so generally deplored. Laboratory science cannot be made a substitute for clinical science. Such substitution again leads the profession into the wilderness of disorder and superstition.

We arrive at the paradox that science (so called) becomes the test superstition to replace and destroy scientific medicine.

RESEARCH INTO THE COMMON COLD

"A Common Cold Research Unit" is being established by the Medical Research Council and Ministry of Health, and will start work in July at the Harvard Hospital, near Salisbury, which was built and equipped in 1941, and given to the Ministry of Health by Harvard University and the American Red Cross as a place for research into communicable diseases.

Laboratory Studies and Human Tests

A statement issued by the Ministry and the M.R.C. says that the problem of the common cold is a particularly complex one, made more difficult because, apart from chimpanzees, which are unsatisfactory for experimental purposes, it has not yet proved possible to study it in animals. Progress towards the discovery of effective means of preventing a number of other diseases has not been made until some way of observing the disease in animals became available. For example, an effective vaccine against yellow fever became possible only when rhesus monkeys, and later mice, were found to be susceptible to the virus. Similarly, not until it was discovered that ferrets were susceptible to influenza virus was any progress made with the study of influenza. Therefore the first objective of the present investigations into the common cold is to find a susceptible animal or, better still, some other laboratory technique which will permit a scientific approach to the problem.

As a check on their laboratory studies, workers at the National Institute for Medical Research will, at least for the time being, require to test on human volunteers the cold-producing activities of materials they are studying. These tests will be carried out at the

Harvard Hospital. The volunteers will for the time being be drawn from men and women students at the universities. First they will be isolated until it is certain that they are free from infection. Then, after a few days' quarantine, their noses will be sprayed with material to see whether or not it contains a virus. While these observations are being made—for a period of 10 to 14 days in all—the volunteers will be out of contact with the outside world and each other except that, to obviate boredom, they will normally live together in pairs. Isolation will not involve complete loss of freedom, for the volunteers will be allowed to move about the countryside around the hospital provided they avoid all human contacts; and they will live in restful holiday conditions. Volunteers are now being recruited from among university students. If more are needed later, an appeal will be made through suitable organizations. Careful selection is necessary, because special qualities are needed and an exact discipline must be maintained. The Medical Research Council is therefore choosing its own recruits, and applications from the general public cannot be entertained.

TUBERCULOSIS CARE IN NORTHERN IRELAND

It was plain from what was said at the inaugural meeting of the newly formed Northern Ireland Tuberculosis Authority (already christened "Nita"), which has been set up under the Public Health (Tuberculosis) Act,¹ that there is to be no restriction upon its field of activity. Indeed, as the Minister of Health (Mr. William Grant) pointed out, the authority's "terms of reference" were to tackle tuberculosis by all recognized methods, from prevention, including education, to treatment in its widest sense—care, maintenance, after-care, and rehabilitation. Its first duty was, of course, treatment of those suffering from tuberculosis and the provision of sanatorium beds. He hoped soon to see proposals for a drive to secure examination of all contacts of tuberculous persons, since this offered such an excellent opportunity for controlling the disease. The Government, he recalled, was going to meet all capital expenses, the full cost of treatment allowances, and 50% of the ordinary maintenance expenses.

At the meeting, which was held at the Parliament Buildings, Stormont, Councillor Percival Brown (Belfast) and Alderman Mac Christie (Coleraine) were appointed chairman and vice-chairman respectively of the authority. As a prelude to the meeting the Minister of Health entertained members and other guests to lunch. Proposing the toast of the new authority, Mr. Grant warmly acknowledged the co-operation he had received from local authorities (he mentioned particularly the Belfast Corporation) in getting the Act on the Statute Book, and the public spirit they had shown in meeting him "magnificently." The burden of tuberculosis care would now fall on those who had so willingly agreed to serve "Nita." Tuberculosis was a serious problem in Northern Ireland; there was much to be done, but he and the Government had the fullest confidence in them and the work they were going to do. The Prime Minister (Sir Basil Brooke), who also attended the luncheon, said that this Act was not the only health measure the Government had in mind, but any health services proposed would be at least as good as those offered in Great Britain.

TUBERCULOSIS IN INDIA

Lady Wavell in an address to the Tuberculosis Association of India on March 27 said that the time had now come when public opinion would demand much greater activity on the part of the State. Referring to the Bhoré Committee's report Lady Wavell said that consequent on the increasing strength of public opinion in matters of the health, and specially on the publication of the report, it was to be anticipated that various Governments and Administrations in India would assume responsibility for the prevention of tuberculosis and treatment and rehabilitation of sufferers from that disease. "Notwithstanding this," Her Excellency added, "the care and after-care of the sufferer, the education of the public, the research and the co-ordination and direction of the education of workers will, in many years to come, make great claims on the association."

The annual report, presented by Major-Gen. R. Hay, chairman of the association, recorded all-round progress during 1945. For more associations were affiliated to the centre, bringing the total to 34. A feature of the report is the training of tuberculosis workers. Refresher courses have been organized in different parts of the country. During the year 32 doctors received postgraduate instruction and four health visitors qualified, while 12 are undergoing training. Arrangements exist for admitting doctors for practical training in the Lady Lillithgow Sanatorium, Kasauli, and the New Delhi Tuberculosis Clinic. The affiliated associations have also been doing useful work. There are 124 tuberculosis clinics and hospitals and sanatoria with 4,384 beds in India. The report, ho

¹ *Journal*, April 6, p. 529.

ever, points out that this number "is grossly inadequate for a country like India, where the average number of deaths from tuberculosis is in the neighbourhood of 500,000 and the number of open cases is about 2,500,000."

The association took the important step of appointing on it corresponding members from other countries with a view to securing the benefit of contact with the best work and workers abroad.

Reports of Societies

PENICILLIN IN SUBACUTE BACTERIAL ENDOCARDITIS

At a meeting of the Liverpool Medical Institution on April 25, with the president, Dr. G. F. RAWDON SMITH, in the chair, Dr. G. SANDERSON and Dr. M. G. McENTEGART read a paper on the treatment of subacute bacterial endocarditis with penicillin.

Dr. Sanderson described the clinical findings in 20 cases treated in Liverpool for the Penicillin Clinical Trials Committee of the Medical Research Council (see *Journal*, March 16, p. 381). Of this group 8 had died, and 12 had survived for periods ranging from a few weeks to over a year. Of the 8 female cases 5 had died, and of 12 males 3 had died. Cases of congenital heart disease (3) had all done well. These findings were of doubtful significance. There seemed to be no clinical indication before starting treatment as to its probable outcome. Penicillin was given in the earlier cases by continuous intramuscular drip, subsequently by three-hourly intramuscular injection into the thigh. Patients preferred the latter technique, which was well tolerated if fine sharp needles were used.

There had been major embolic accidents in seven cases; cerebral embolism had been most frequent, including two cases of subarachnoid haemorrhage, but splenic, renal, femoral, and popliteal embolism had also been encountered. One patient, who had had a subarachnoid haemorrhage during treatment, had residual diplopia and difficulty in walking. A second patient developed recurrent massive haematuria during convalescence, and this eventually necessitated nephrectomy for left renal aneurysm. These two cases illustrated "recovery with sequelae." Such vascular complications would be encountered from time to time in successfully treated cases, and both physicians and surgeons would need to be aware of this new syndrome. In the second case mentioned timely surgical intervention was a life-saving and health-restoring procedure. The 8 fatal cases were summarized as follows:

Case No.	Age	Dosage (Mega Units > Days)	Time of Death	Remarks	Result
3	42	0.5 x 10	7 days after completing treatment	Death from cerebral embolism and uraemia. Post-mortem cultures: pyocyanus but no streptococci. Sections show healing	
7	18	0.25 x 25	5 months later	No relapse during two months under observation. Death from ruptured aortic aneurysm	
9	22	0.2 x 7	7th day of treatment	Moribund on admission	
10	30	0.2 x 25 (interval 65 days)	2½ months later; 9th day of re-treatment	Blood positive at end of course. Refused to stay in hospital. Re-admitted gravely ill	Failure of 0.2 x 25
11	25	0.25 x 28 (interval 12 days)	7 weeks after 2nd course	Blood positive immediately after both courses	Failure of 0.25 x 28 and 0.5 x 28 C.C.F.
13	62	0.25 x 28	5 months later	No relapse of infection. Death from congestive failure	
14	30	0.25 x 28	6 weeks later	Congestive failure. Necropsy showed no active endocarditis	C.C.F.
17	34	0.26 x 26	26th day of treatment	Necropsy refused	

These cases indicated that most failures were not failures of penicillin, and suggested that even when optimum schemes of dosage had been worked out a considerable mortality must still be anticipated, probably of the order of 25%. The two deaths from congestive cardiac failure (C.C.F.) were important, as most published series had included deaths from this cause. In discussing dosage Dr. Sanderson quoted Christie's figures as show-

ing the value of a large-scale investigation. Of the Liverpool cases treated with 0.5 million units daily for 10 days, three out of five had recovered, but no other centre had any success with this regime. The present tendency of dosage was upwards both in quantity and in time.

Laboratory Control

Dr. McENTEGART described the laboratory control of the investigation in relation to blood cultures, penicillin sensitivity of the organisms isolated, and serum and urine penicillin levels during treatment. Attention was drawn to the apparent lack of correlation between the coefficient of resistance (within the limits shown by the organisms isolated from Liverpool cases) of the infecting organism and the ultimate outcome, and cases were quoted in support of this conclusion. Observations on serum penicillin levels suggested that the onset of renal failure was accompanied by some degree of penicillin retention.

In the discussion the PRESIDENT commented on the greater success in the earlier cases to be treated than in the later ones. He wondered if penicillin might be at any rate partially responsible for the emboli so often observed. He was surprised that extensive dental extractions were considered an aetiological factor in infective endocarditis, as it was unknown at the Liverpool Dental Hospital, where major dental operations were frequent.

Dr. H. FULFORD said that one of the patients demonstrated at the meeting was seen by him before admission to the Royal Infirmary. He gave a history of tooth extraction for apical abscess three weeks before the onset of his symptoms. In a recent American review of 347 cases of subacute bacterial endocarditis the incidence of tooth extraction was 10%. Dental sepsis appeared to be the most important primary focus of infection. Most edentulous patients who developed bacterial endocarditis were infected with organisms other than *Str. viridans* (enterococcus, staphylococcus, and gonococcus). He felt that in future "oral clearance," particularly in patients with congenital heart disease or a history of rheumatic fever, should be considered an operation requiring pre- and post-operative penicillin therapy. Total clearance at one sitting in the dentist's chair should be a thing of the past.

Dr. R. M. EVANS recalled two cases of apparent cure in which the sudden onset of congestive cardiac failure several weeks after the penicillin treatment was found at necropsy to be due to a ruptured aortic cusp. In both cases vegetations were absent, and the bacterial infection apparently abolished, leaving the cusps damaged by scarring.

TREATMENT OF CANCER OF THE CERVIX

The April meeting of the North of England Obstetric and Gynaecological Society, held at Leeds, was devoted to a discussion on the treatment of cancer of the cervix uteri.

Mr. D. W. CURRIE, of Leeds, described a series of 41 cases on which he had performed a Wertheim's hysterectomy, collected between the years 1935 and 1946, with no primary mortality. Of these, 8 had died of the disease, and 6 out of the 11 operated upon five years or more ago were still alive. He was of the opinion that the operation was the treatment of choice in the early type of case, and that the operation should be preceded by treatment with radium to clear up sepsis and to minimize the risk of implantation of cancer cells in the vault of the vagina.

Dr. M. C. TODD, of Manchester, and Dr. G. W. BLUMFIELD, of Sheffield, described their technique for the treatment of this growth with radium. Dr. Blumfield stressed the importance of obtaining a reliable opinion on whether the type of cell in any biopsy was such as to be likely to react favourably to irradiation. He was of the opinion that there should be the closest co-operation between the gynaecologist, the radiotherapist, and the pathologist before coming to a decision as to which was the best form of treatment in any given case. Mr. Currie deplored the fact that many cases were sent direct to the radium expert for treatment with radium without letting the gynaecologist have the chance of giving his views on whether surgery should be employed or not.

Many members discussed the problem, and Mr. Currie was congratulated on proving that the risk of a Wertheim's hysterectomy was no greater than that of an ordinary hysterectomy, when it was performed by an expert surgeon.

Assistants and the Health Service

SIR,—I have read the condensed White Paper on the proposed National Health Service and have also followed with interest and ever-increasing apprehension the numerous reports, letters, etc., appearing in your columns, but have so far failed to find any reference to the position of assistants.

I am now aged 31, with 6½ years' war service to my credit, and was demobilized from the R.N.V.R. last December. Having no available capital and lacking any desire to invest borrowed money in a partnership with a State medical service "round the corner," I was forced to take an assistantship. What, I wonder, will be my position and that of the hundreds of other similarly placed ex-Service medical men now acting as assistants when the new service comes into force? Many of us, like myself, have no surgeries of our own. We live in furnished rooms and see patients in the consulting rooms of our principals. We have no patients of our own because, theoretically at any rate, all the patients we see are those of the practice.

With regard to the proposed direction of doctors, positive or negative as it may be, I feel that I have had my fair share of "draft chits" in the Navy, and on my demobilization looked forward to a free choice of locality in which to practise. This, it seems, was a vain hope.—I am, etc.,

Falmouth.

W. J. PATTON.

Medical Students and the Bill

SIR,—We have been sent a questionnaire on the Health Bill by the British Medical Students Association and we favour the attention of both undergraduates and graduates in the wide issues involved.

1. The bulk of it refers to points of method, technique, administration; only one question touches on policy: "Do you approve or disapprove in principle of the establishment of a comprehensive National Health Service?" The quality of that service is not defined or queried; and it is the quality that matters to the patient, not the mere presence of a service. We are reminded of the "control of the agenda technique" of any policy of force.

2. We doubt if responsibility can or ought to be given to students (or doctors) to answer some of the questions, as they concern future events and/or highly technical matters of administration.

3. Some of the questions are not worded in intelligible language. "Benefits and contributions" are to be "applied" (? like the thumb-screw), and "efficiency" is freely used without definition so that its meaning can range from "compulsory" to "a bigger and better Civil Service."

4. Only two questions out of a total of about 20 are answerable if the policy of the Bill is not accepted. Further, there is no opportunity for "contracting out" of answering a question, the choice being "Yes," "No," and "Don't know." This does not give an opportunity to exercise the "negative vote," which is valid in this questionnaire as only one policy is presented. By such a vote we mean the purposeful refusal to answer a question.

5. The executive of the B.M.S.A. points out that its finally expressed views must of necessity be the views of the majority answering this questionnaire, and such views are to be put forward to the Minister and the country as the views of the medical students of the country. Once more the fallacy of mob or majority rule prevails. That minority views are not represented with equal fairness we can only regard as one of the triumphs of totalitarian philosophy, and we have no compunction in denouncing this as alien, as the rule of force, as being of the creed of our recent enemy. If democracy means the rule of the majority and the suppression of the minorities, then cut out democracy. This is in absolute contradiction to the ethical concept of medicine—that the individual is of supreme importance—the condition of acceptance being that he harms not his fellows (thus arises common law).

In conclusion, we hold that the concern of the individual doctor and student is one of policy, and that the administration of that policy, its method of application, is to be formulated after the policy is agreed to, and by the co-operation of those concerned with its administration. And we agree to this policy: "that full facilities of medical care be extended to the whole community under conditions of privacy, freedom of contract,

and personal responsibility of doctor directly and solely to the patient, subject only to the common law and the ethical tradition." We therefore reject the Bill and any other proposed scheme where a central authority can interfere in the doctor-patient contract. We regard the Bill, by transferring responsibility to the State, as being a measure that violates our principles of association, as being a measure conflicting with the British tradition and the fundamental nature of man. We reject it in its entirety, fully realizing it contains in administrative technique much good.—We are, etc.,

GEORGE H. BLAIR.

The G.P. in Consultation

SIR,—May I be permitted to join issue with Dr. R. G. Blair on his statement (May 11, p. 733) that "the whole trend of modern medicine is to pass the complaints of each and every patient through a series of watertight compartments of mechanical and laboratory investigation, while the diagnosis and treatment are postponed for the assessment of the findings." Such indeed was the trend of medicine in this country a quarter of a century ago, and this trend now carries all before it in the United States. But it was exactly the recognition of this trend and of its dangers which twenty years ago led in this country to the foundation of the Association of Clinical Pathologists. The precise aim and purpose of clinical pathology as developed by the association is to eliminate the watertight compartments and to bring all branches of laboratory diagnosis into close and efficient contact with clinical practice.—I am, etc.,

Wolverhampton.

S. C. DYKE,
Vice-President, Association of Clinical Pathologists

What is Clinical Pathology?

SIR,—Since the B.M.A. proposes to publish a new journal, one on clinical pathology, it is perhaps proper to ask what this subject really is. One commonly held view is that a clinical pathologist is the laboratory worker who does the morbid anatomy, the bacteriology, the chemistry, and the haematology for a hospital which is too small, too poor, or too stupid to employ an expert in each. This is a shameful misuse of two words that separately were of good caste, and that wedded might well be used to distinguish the pathologist (laboratory investigator of disease) working with human material from those whose interests are in animal pathology (veterinary and comparative pathologists, and those working on experimental cancer or other diseases). The Goodenough report not only uses the term clinical pathologist, but seems to believe that there should be professors of clinical pathology, and yet the nearest it comes to giving a definition is to describe the ideal clinical pathologist as one who is an expert haematologist, a liaison officer between the clinician and the morbid anatomist, bacteriologist, and chemist, and capable of doing the simple diagnostic work that properly belongs to the subject of these three colleagues. Accepting this description for the moment, we may presume that there will be few if any publications in this proposed new journal on the liaison aspects of this man's work, and it would therefore be accurate enough to call it "The Journal of Haematology and the Simpler Clinical Laboratory Procedures." The absurdity is obvious. Let us therefore reject these hazy ideas and agree that "clinical pathologist" means a laboratory worker attached to and performing diagnostic work for a hospital. It has not been stated yet whether the sponsors of the new venture mean to exclude any of the four specialties that comprise clinical pathology. If not, and if the morbid anatomist, the bacteriologist, the chemist, and the haematologist are all to be accepted, then let us call it "The Clinical Laboratory Journal." At least let us be clear about the purpose to be served and the field to be covered by this new journal. There is not much room on the bookshelf.—I am, etc.,

Glasgow.

ALAN C. LENDRUM.

Resumption of Treatment at Spas

SIR,—Recently a number of doctors have asked me for information as to whether the spas of this country are still functioning as such, how patients should be referred to them and the general procedure of getting them there.

In answer to the first question, all the spa hydrotherapy and physiotherapy establishments are now open, but accommodation is, in many cases, still somewhat limited, owing to the delay in "de-requisitioning" hotels. There are three hospitals to which cases may be referred—the Royal National Hospital for Rheumatic Diseases, Bath, the Royal Devonshire Hospital, Buxton, and the Royal Bath Hospital, Harrogate. In most hospitals there is a waiting list, but application for particulars and entry forms should be made to the respective registrars.

With regard to private patients, these should be referred with a letter from their private doctor, preferably to a specific doctor at the spa chosen, or, failing this, to the spa director, who will forward on demand a list of doctors willing to supervise treatment. Accommodation consists of hotels, lodgings, or nursing homes, and facilities available at each spa can be forwarded to the patient by the spa director or physician concerned if some information is sent to him of the degree of incapacity of the patient, his means, and his preferences in the matter. The average stay for treatment is three weeks, but in some cases, of course, several months will be required if orthopaedic procedures need to be instituted. On this basis there are usually inclusive charges in addition to individual charges, arranged for a course of some eighteen treatments of whatever type the physician may order at the cost of a little under £6.—I am, etc.,

Bath.

G. D. KERSLEY.

The Catheter and the Prostate

SIR,—I am sure that every prostatectomist will agree that congratulations are due to Mr. Wilson Hey (May 18, p. 757) on his low mortality rate for such a large series of prostatectomy cases. His figures proclaim the extent to which he has triumphed over the twin enemies—haemorrhage and sepsis. It is proper, I feel, to regard the mortality rate as the primary concern in the results of prostatectomy. I personally am in hearty agreement with the writer on the general principle of the evils of the catheter in prostatic cases. I suppose that every surgeon who is largely concerned with prostatectomy is constantly exercised to improve his results, so that I am sure I cannot claim to be exceptional if I confess to having spent my surgical life in such an endeavour. My most recent efforts involving modifications of technique towards this end are represented by a modest total of 95 cases of suprapubic prostatectomy for simple enlargement, comprising 40 one-stage and 55 two-stage cases, with a total mortality of 1 (1.05%). The death was in one of the two-stage cases. Over the same period I performed suprapubic cystostomy on 18 other cases of simple enlargement, with the ultimate hope of prostatectomy for some of them. There were two deaths amongst these. Thus there was a total mortality of 2.6% in 113 cases of simple enlargement of the prostate submitted to open operation.

Briefly, the points I pay special attention to are: (1) Avoidance of urethral instrumentation as much as possible; (2) decompression by the suprapubic route; (3) wide indications for two-stage prostatectomy; (4) open operation in all cases; (5) careful toilet of prostatic cavity, which is then packed with Paul's tubing.

My experiences prevent me from endorsing Mr. Hey's views on the dangers of suprapubic drainage. I am still unaware of any evidence that the urine during the convalescence following any method of prostatectomy can be kept free of pus or organisms. I feel that while the benefits of a preliminary cystostomy are sufficiently well known not to need elaborating, the evil consequences from the introduction of fresh organisms through the suprapubic approach are much less than those which result from urethral instrumentation. Pre-operative indwelling catheter drainage, although it may result in a fall in blood urea in a most dramatic way (this object may be achieved equally well by other means), tends nevertheless to set up inflammation not only in the urethra but also in the prostate. The evidence that the latter organ is so affected is the regularity with which a certain amount of oedema is to be found in the prevesical space when the indwelling catheter is used pre-operatively. Moreover, the tendency to renal infection, septicaemia, and pyaemia from the instrumentation of the unhealthy prostate needs no emphasis from me.

My experience is that infective complications of all kinds, particularly those of the chest, commonly follow suprapubic cystostomy if urethral instrumentation has been employed in the pre-operative period; also after prostatectomy the same events may occur, as, for example, when an ill-timed effort is made to safeguard against post-prostatectomy obstruction. On the other hand, such incidents have been far less frequent amongst my cases when the instrumentation has been restricted to the actual operation session. In the more distant past I found that cystoscopic prostatic cases at all sorts of intervals—sometimes several weeks—before the prostatectomy gave me a certain number of cases with infected urine, and occasionally with something worse, for the prostatectomy. More recently, therefore, I have chosen what I consider the lesser evil—cystostomy immediately preceding operation.

With regard to chronic urinary infection after two-stage prostatectomy: if strict attention is paid to removing any vesical diverticula which are present (I removed diverticula in 14% of this group of prostatectomy cases) and a close watch is kept for the slightest sign of post-prostatectomy obstruction, such cases should be very exceptional. At the present time many of the younger surgeons are coming out of the Services, and have for a period been out of touch with prostate work. Some of these will be faced at once with the problems of prostatectomy, and with the difficulty of choosing how to proceed from the many modern methods of removing prostatic obstruction, all requiring a good deal of skill and experience. It is important, therefore, that they should know that suprapubic prostatectomy combined with bladder drainage can be done with relative safety, provided a sound technique is employed.—I am, etc.,

London, W. 1.

H. P. WINSBURY-WHITE.

SIR,—In your issue of May 18 Mr. Wilson H. Hey suggests that all cases of retention of urine, complete or incomplete, should be operated upon before a catheter is passed. He also states that the operation he performs entails a twelve-hour preparation with chemotherapy. The combination of these two ideas does not seem to be practicable. If, as he lays stress upon, the important factor is sepsis, surely his remarks can refer only to the prostate not complicated by acute retention. Even assuming we dispense with the chemotherapy, I find it hard to believe that it is better for the patient with an acute retention to have to wait an extra hour or so, while the theatre is prepared and a surgeon called in order to operate, than to give him immediate relief by the catheter.—I am, etc.,

St. Mary's Hospital, W. 2.

SEYMOUR EDELMAN.

Shock Treatment of Bronchial Asthma

SIR,—The article of Dr. Z. Godlowski (May 11, p. 717) is a further contribution to the most difficult problem of treating the so-called "allergic" asthma—i.e., that in which no organic cause can be found (strictly speaking, all asthma cases are allergic). The insulin treatment represents another example of non-specific protein shock, which, like Godlowski, I have pointed out to be the most rational treatment in this type of asthma. Unfortunately, insulin therapy has several disadvantages. It lacks simplicity, it is slow, and it is not safe except under expert supervision in hospital.

A simpler method of applying (non-specific) protein shock which can be used in general practice is one I described in 1939 and 1945 and which was first published in Austria and Switzerland in 1933. The drug used was "pyrifur," a *Bacillus coli* vaccine (now manufactured in this country) which originally was used in the treatment of G.P.I. in place of malaria.

"Pyrifur" is given intravenously, on an empty stomach, in the morning, and usually one injection (lowest strength, 50 million germs per ml.) is adequate. Four to five hours after the injection a rise of temperature occurs, associated with rigor, headaches, sometimes sickness and profound depression (symptoms resembling influenza or malaria), but three or four hours later this subsides again and the following day the patient feels almost normal except for some weakness. The method is safe, and no special laboratory tests are required. Only in decompensated heart cases with obvious clinical symptoms and signs have I refrained from using this treatment.

The administration of the drug is simple and it can be employed in general practice, as I have always done. I have found that within a few days the asthma disappears, and I have seen quite a number of cases without recurrences for four or five years.—I am, etc.,

Spennymoor.

E. BRAUER.

Penicillin in Eye Work

SIR,—Penicillin has been used extensively in eye work, not only in conjunctivitis and infections due to specific organisms but as prophylaxis in pre-operative and post-operative cases (Keyes, *J. Amer. med. Ass.*, 1944, 126, 610). It has been realized that penicillin in isotonic saline solution, administered as drops, was not ideal because its effect is so transient and repeated instillations are necessary to maintain an effective concentration. Some other base with a higher viscosity was sought. Before discussing the substance used, it is necessary to mention the other preparations of penicillin commonly used for eye work. Penicillin cream made with a lanette wax base was sometimes found to be irritating to the conjunctiva. Penicillin lamellae would be ideal if a gelatin or similar base was used, but the present type, a small compressed tablet, excites a foreign-body reaction. A solution of "carbo wax 4,000" was suggested as a liquid base for penicillin.

Carbo wax is soluble in water, and a 70% weight in volume solution has a viscosity similar to castor oil. Briefly, its properties are as follows: a condensation product of diethylene glycol, its formula is $(\text{CH}_2\text{OH})_2(\text{CH}_2\text{OCH}_2)_n$ and its melting-point 50–55° C. (McClelland and Bateman, *Chem. Eng. News*, Feb. 10, 1945). Experiments by Smyth *et al.* (*J. industr. Hyg.*, 1942, Sept. 24, p. 281) show that it is relatively non-irritant to the skin and to the mucous membrane of a rabbit's eye.

The solution of penicillin and carbo wax was prepared as follows. Carbo wax 4,000 (supplied as flakes) was dissolved in sufficient Sørensen's buffer (pH 8) to produce a solution containing 70% weight in volume. This solution was filtered, hot, through filter paper, distributed in small screw-capped bottles, and sterilized by autoclaving at 115° C. A solution of penicillin was added aseptically to the sterile carbo wax solution when cold. The final pH was 7 as measured by a comparator using a universal indicator. The preparation was found non-irritant to normal eyes and was used in cases of conjunctivitis, corneal ulcers, and in pre- and post-operative cases, 3 to 4 drops every four hours being instilled. The base described above is suggested, because of its higher viscosity and its inert and neutral properties, as a suitable vehicle for the ocular instillation of penicillin. Carbo wax 4,000 was supplied by General Metalurgical and Chemical, Ltd.—We are, etc.,

JOHN C. H. HANSON.

Hertford County Hospital

Toxicity of Uranium

SIR,—With regard to the significance of uranium in its relation to atomic energy your annotation (March 16, p. 397) dealt with experiments by the American authors Gustafson, Koletzki, and Free, who found that dogs given big doses of uranyl nitrate intravenously developed severe tubular necrosis of the kidneys, resulting within a short time in anuria, uraemia, and death. Sodium citrate given orally or intravenously protected the kidneys against uranium poisoning.

In experiments carried out more than thirty years ago J. Pohl found a different type of renal damage—namely, a subacute nephritis resulting in death, due to very small doses of uranyl nitrate hypodermically administered in rabbits (*Arch. exp. Path. Pharm.*, 1911–12, 67, 223). Unlike the acute nephritis with uraemia mentioned above, the main feature of the subacute nephritis is the lack of anuria and uraemia, but an obvious diuresis with a more or less increased excretion of N and NaCl—in other words, death occurs while the kidneys are fully functioning. The name "scouring nephritis" proposed by Pohl seems to be appropriate. Later, I myself (*Z. klin. Med.*, 1915, 81, 355) and in collaboration with K. Siegfried (*Z. exp. Path. Ther.*, 1920, 21, 380) tried to modify the course of this subacute nephritis in rabbits and found that daily intravenous injections of calcium lactate, and also of hypertonic NaCl solution, increased the manifestations and accelerated the

course of the poisoning, 0.9% NaCl solution being without any influence. These findings are remarkable in view of the therapeutic effect of sodium citrate seen by the American authors. As a result of specially arranged experiments we formed the theory that uranyl nitrate has a peculiar affinity for the kidneys, the other organs not being primarily affected. Microscopically we found glomerulonephritis when uranyl nitrate was injected directly into the renal artery.

Some unpublished experiments by Siegfried on that problem will be found to be of interest. He told me that rabbits poisoned by uranyl nitrate did not die but recovered when they were given a diet of vegetables and salad; they were eager to eat earth, to which fact he attached special value. I cannot remember whether Siegfried (he died about ten years ago) killed the animals in order to examine their kidneys histologically.—I am, etc.,

Kingston-upon-Hull.

L. DUNNER.

National Research into Tuberculosis

SIR,—Nearly six months ago (Dec. 1, 1945, p. 781) one of us (G. R. W. N. L.) wrote a letter to the *Journal* emphasizing the urgent need for organized research with a view to discovering a chemotherapeutic compound which will cure tuberculosis. This was followed by a few letters from colleagues and a very encouraging reply from Dr. Frederick Heaf (March 2, p. 327). Many important aspects of this problem were mentioned in these letters:

1. "The defeatist attitude which exists in the field of tuberculosis is to be deprecated, and it is a sad state of affairs that we are content to spend millions on palliative measures alone." (Dec. 1, 1945, p. 781.)

2. "The difference between the tuberculous patient and casualty from all other causes in persons of the same age is so tragically glaring that it cannot be missed. Whereas a patient in the casualty group, with the help of sulphonamides, penicillin, and surgery stands a very fair chance of getting over his disability, one in the tuberculous group, in spite of all modern medical and surgical treatment, stands with the sword of Damocles perpetually hanging over his head." (Jan. 5, p. 32.)

3. "Tuberculosis costs the country many millions of pound every year and destroys or cripples thousands of persons in the prime of life, and yet our efforts to combat the ravages of this scourge are still spasmodic and half-hearted. We are still unable to prevent persons becoming tuberculous or to offer them a cure and the infection continues to take its toll of children and young adults as it passes through the population practically unchecked." (March 2, p. 327.)

4. "Now that methods of treatment in pulmonary tuberculosis are coming under critical review it is being increasingly realized that they are over-used and, to a great extent, over-rated. The answer to the problem of tuberculosis has not yet been discovered. No effort or expense should be spared in the attempt to discover a chemotherapeutic substance to cure tuberculosis, and we should tolerate no delay. It is a prime responsibility of the medical profession and the Government, in meeting this national problem, to set up a special research unit with this object in view." (Dec. 22, 1945, p. 901.)

After reading through these extracts it is somewhat surprising that the response from the medical profession should have been so small. Is it because doctors in general are not easily drawn into discussion on matters which they consider important? Apparently not; for the columns of the *Journal* were occupied every week from November 24 to December 22, 1945, with fifteen letters on "Artificial Pneumothorax Refill," and on "Stethoscope v. X Rays" eighteen letters appeared between January 5 and May 11, 1946, when the correspondence had to be closed. It is an unhappy reflection on the outlook of the medical profession that it is so ready to dilate on medical minutiae, whereas fundamental issues leave it entirely unmoved.

Previous Governments have always been niggardly in their grants for medical research, and the present Government has so far given no indication that it intends to depart from the general rule. It might have been expected that included in the plan for reorganization of medical services would have been specific and generous provision for medical research. So far as we know the Government is content to continue with its annual pittance of £215,000 for medical research throughout the length and breadth of the country. Medical men must be aware of the pressing need for investigations likely to throw light upon practical problems of the moment. This work is of the very

first national economic importance. The Government must be urged to make every effort to contribute towards medical research so that not only general scientific knowledge but also curative treatment can be advanced to add to the heritage of this country.

While it is no wish of ours to introduce a red herring into this correspondence, any discussion of the problem of tuberculosis would be incomplete without reference to the question of pasteurization of milk. The evidence in favour of this measure for ensuring a safe milk supply is overwhelming and incontrovertible. The system of grading milk under the Milk (Special Designations) Orders is particularly dangerous in that it lulls the public into a false sense of security. Why, then, is the Government so tardy in introducing a measure which will render milk safe without diminishing its nutritive value? The *Bulletin of the Health Organisation of the League of Nations* (June 1937) sums up the position:

"The fear that pasteurization was detrimental to the food value of the milk has undoubtedly deterred many doctors in the past from supporting compulsory pasteurization. The fear appears to be entirely groundless and should now be removed to the limbo of disproved and forgotten prejudices."

Our plea is for immediate legislation insisting on pasteurization of all milk supplies and the speedy organization of systematic research for the prevention and cure of this terrible scourge on the young people of the world. At a conservative estimate tuberculosis costs this country £15 000 000 annually whereas it was reported the other day that one of the greatest authorities in matters of chemotherapy considers that £1 000 000 to spend on tuberculosis research should produce definite results within ten years. However distant the goal a start must be made now. It is up to us of the medical profession to insist that the Government take immediate steps to this end. By so doing the health of the whole country—for that matter of the whole world—would be changed for all time. We are, etc.

S. M. HILTON

GEORGE R. W. N. LUNT

Preston Hall Hospital, Kert.

Treatment of Congenital Hypertrophic Pyloric Stenosis

SIR,—I read with interest Dr. N. M. Jacoby's article (May 11, p. 721) on the treatment of congenital hypertrophic pyloric stenosis, with its excellent criteria for the differentiation of medical and surgical cases. His anxiety for the child's attendants was admirable—whilst the case was under his care—but as this never appears to extend beyond the day the infant is discharged from hospital—a period of some ten days—I feel he takes rather too optimistic a view of what takes place after this time.

I am still rather in the dark as to how long the feed volume reduction continues. Does vomiting return at all when the volume is increased? If it is kept small what weight does the child put on in subsequent weeks? I should like to quote two cases showing that the history of a pyloric stenosis extended considerably beyond the tenth day.

Case 1 Surgical.—Birth weight, 7 lb (3.2 kg). Normal birth at full term. Breast fed. Vomiting started at five weeks (8 lb 5 oz—3.7 kg), becoming increasingly projectile in twenty-four hours, and by the third day there were constipation, a palpable pyloric tumour and visible peristalsis. Operation was performed immediately. Weight was stationary during the week preceding the operation followed by a 5–7 oz (140–200 g) gain weekly. Weight 12 lb (5.4 kg) at three months, 17½ lb (8 kg) at six months.

Vomiting continued to be projectile for about three days after operation and then decreased, but there was some non-projectile vomiting after every feed until six months, when the child had started to take solid food. At a year the vomiting had ceased entirely.

Case 2 Medical.—Birth weight, 6 lb 11 oz (3.1 kg). Three weeks premature. Caesarean section for placenta praevia. Artificially fed. Digestive upset with frequent loose curdy stools and occasional non-projectile vomiting from 7 to 21 days. Projectile vomit once on seventeenth day, once on eighteenth day, slight improvement in general condition, then gradual deterioration. At seventh week constipation, small non-projectile vomits after each feed, abdomen distended, palpable pyloric tumour, visible peristalsis. Medical treatment advised: "Pylostropin" (Clay and Abraham) atropine methyl nitrate 1/750 gr (0.09 mg) lamella ten minutes before each feed for seven days, then before decreasing numbers of feeds for

the next fourteen days. Vomiting became less; distension disappeared, and there was a motion every twenty-four hours at first, then at slightly longer intervals.

Weight gain very slow at first, weight at three months was 9 lb 8 oz (4.3 kg), since then a rapid gain, now 12 lb (5.4 kg) at four and a half months. Still vomiting happily (literally!) from 4 to 2 oz (15–60 ml) after most meals, though the larger vomits are getting less frequent.

I am afraid my experience in this field is limited but probably (I hope) unique, in that these two cases are my sons and neither of them was in hospital, so that I had ample opportunity for studying their after-care—I am, etc.,

Liverpool

MARGARET SMYTH

"Cord Round the Neck"

SIR,—Eight years ago, at a meeting of the Society of Obstetrics and Gynaecology of Athens, I presented a case of a multipara who gave birth to a living child with six rings of the umbilical cord around his neck. The total length of the cord was about 5 ft. (150 cm).

In 1944, when attending a primipara the foetal heart stopped abruptly at the first stage of the labour, the cervix being three fingers dilated. When the delivery took place a tight cord was found around the neck, and that was the only apparent cause of death—I am, etc.,

Jesop Hospital, Sheffield

P. P. PANAYIOTOU

SIR,—With regard to this controversy, I should like to mention a peculiar condition which I once met with. I was called in by a midwife for delay in the second stage of labour, but was able to deliver without the use of forceps by pressure on the fundus. The child was just dead when delivered, and the cord was three times round the left arm and twice round the neck. The arm below the mark made by the tight cord was atrophied and was only half as long as the right arm and perhaps a third of its thickness. Death, I should think, would be due to the final stoppage of the circulation in the cord during the last stage of delivery.

Cord round the neck is a frequent cause of delay and weak pains in the second stage, and it appears sometimes to be responsible for shoulder presentations, etc.—I am, etc.,

Wallasey

F. WILLIAM INMAN

Sjogren's Syndrome with Rheumatoid Arthritis

SIR,—Prof. Arnold Sorsby, as he kindly offered to do in his letter (May 18, p. 774) has demonstrated to me the association of the keratoconjunctivitis sicca of Sjogren's syndrome with rheumatoid arthritis. What interests me also is that, on the other side, he has found that Sjogren's syndrome is an exceedingly rare complication of rheumatoid arthritis—I am, etc.,

London W 1

F. PARKES WEBER

Compulsory Vaccination

SIR,—At the recent Special Representative Meeting a resolution was proposed deploring the decision of the Minister of Health to abolish compulsory vaccination. The Chairman of Council, however, made it clear that the decision had been made on expert medical advice and on the ground that compulsion was acting as a deterrent. It was considered that propaganda on lines similar to that adopted in the case of diphtheria would be more likely to produce desired results. The resolution was therefore negatived.

With due respect to those who tendered this advice it may well be argued that no sort of parallelism exists between smallpox and diphtheria, since the former is not a prevalent disease, nor has it been so for the past fifty years. Many doctors have never seen a case, and for the general public it has lost its terror. Moreover, in all but exceptional cases diphtheria inoculation is without reaction, whereas vaccination produces a nasty little sore and a varying degree of malaise. It is not hard to see that propaganda will have no easy task. It is probable that the more intelligent public are quite unaffected one way or the other by the compulsory clause, while the ignorant are at least as much influenced by mental laziness as by passive resistance and are even less likely to "contract in" than they are to refrain from "contracting out." It may yet require a

severe smallpox outbreak to re-establish the necessity for vaccination. Active opposition to the compulsory clause is long a thing of the past, but once the rule is rescinded it will prove a most thorny and difficult matter to re-enact it if propaganda fails.—I am, etc.,

Derby

E. D. BROSTER.

The Population of India

STR.—Sir John Megaw's call (March 9, p. 343) for a commission of inquiry into the social and other customs responsible for excessive multiplication of population in India is likely to be a cry in the wilderness. Since the creation of separate electorates, and the provision of seats in the legislature according to the number under each religious denomination, capture of positions of power has become dependent entirely on numbers and not on merit or capacity. With separate electorates at every stage and with the statutory declaration that appointments—even specialist appointments, such as surgical appointments, V.D. appointments, appointments in eye hospitals, irrigation engineers, electrical technicians—will be distributed among different communities according to their number in population, matters have reached such a stage that multiplication and not qualification has been the sole determining factor. The scandal of holding back the constitution of a famine control body because sufficient Moslems were not available in Bengal, even though famine was then knocking at the door, was commented upon by the Woodhead Commission.

In such a state of affairs any advice to control prolific baby production will be considered inimical advice. Some years ago, at the Bengal Conference of the Indian Medical Association, a resolution to request the Government to start birth control clinics was thrown out by a majority of doctors who are overwhelmingly Hindu and who probably felt that the advice would be taken by the Hindus and not by other more backward intellectually and culturally unprogressive communities, and the result would be to tilt the balance further in favour of communities in which polygamy has not yet become something to be ashamed of, where temporary marriages are customary. Already Moslems, who were a minority in Bengal 70 years ago, have become the majority, and in the whole of India in 50 years the Moslems have increased by 80% while the Hindu population has gone up by 40%.

Social reform propaganda has also proved a boomerang in its results. Many years ago child widows could be counted by the 100,000 among Hindus, and as widow remarriage was unknown except among the lower castes this was a salutary check on the growth of population. So was also the institution of *Sanyasis*—celibate male monks—among Hindus. There were several millions of these people who at least could not procreate. Such institutions are becoming rarer with westernization. Sir John Megaw's well-meant advice is therefore likely to meet with a chilling reception in the present atmosphere of scramble for political power.

There is one redeeming feature to which one could call the attention of our friends. The over-all density of population is 168 per sq. mile, which is less than that for Europe minus U.S.S.R. If therefore India was industrialized even to something like the backward countries in Europe, India could easily feed herself, because even in the worst days of famine in Bengal there was hardly scarcity of grain. It was far more commonly inability to pay the State-controlled price, just as at present so-called destitutes are still daily dying in the streets of Calcutta for want of money, not grain.

Lord Wavell, who has proved to be one of the best Viceroys India has seen, even if he is the last Viceroy, is initiating country-wide schemes which are expected to raise the production of the soil. The yield of rice per acre in Bengal is about one-third of that in Spain and less than one-half of that of Japan, and the yield is getting less and less. A progressive Government could any day increase the yield to three or four times the present figures, and then scarcity of cereals would be impossible for at least the next 50 years and the poor man would have a far more satisfying diet than he has ever known.

In the present morbid atmosphere the way of deliverance lies therefore in calling not for limitation of families but for industrialization and co-operative methods of increasing the yield from the soil.—I am, etc.,

Calcutta

N. R. SEN GUPTA.

Obituary

T. H. BRYCE, M.D., F.R.S.

Prof. T. H. Bryce, who died in hospital at Oxford on May 16, held the Regius chair of anatomy in the University of Glasgow from 1909 to 1935, when he received the title of emeritus professor. He helped Glasgow to a leading place in the modern science of anatomy and did much original research in embryology and cytology; he also gave memorable service to anthropology and was a distinguished archaeologist.

Thomas Hastie Bryce, son of William Bryce, M.D., of Edinburgh, and a cousin of Viscount Bryce, the eminent jurist, statesman, and diplomat, was born at Dalkeith on Oct. 20, 1862. From Edinburgh Collegiate School he went on to the University of Edinburgh, graduating M.B., C.M. in 1886, and M.D. (with gold medal) in 1901, having become a Fellow of the Royal Faculty of Physicians and Surgeons of Glasgow in 1890. Later he was awarded the Keith prize by the Royal Society of Edinburgh, which elected him a Fellow. After working as demonstrator of anatomy at Edinburgh under Sir William Turner he was appointed lecturer on anatomy at Queen Margaret's College, Glasgow, in 1890; two years later he became lecturer in the same subject at the University of Glasgow, holding the post until 1909, when he succeeded Prof. John Cleland in the Regius chair. On his retirement in 1935 he was succeeded by Prof. D. M. Blair. For many years he was curator of the anatomical and archaeological collections in the Hunterian Museum in Glasgow and devoted much time and skill to the arrangement and classification of the specimens. He had a European reputation as an anatomist and was especially distinguished for his work on human embryology, an important contribution being the monograph written with Prof. Teacher and Prof. Munro Kerr on the early development and embedding of the ovum.

Prof. Bryce was one of those responsible for the eleventh edition of *Quain's Anatomy*, contributing the sections on embryology, osteology, and arthrology. He was elected F.R.S. in 1922, and two years later gave the Rhind Lecture at Edinburgh University, taking as his subject "The Anthropological History of the Scottish People." He wrote a number of memoirs and papers on anatomical and anthropological subjects which appeared in the *Journal of Anatomy and Physiology*, in the *Quarterly Journal of Microscopical Science*, and elsewhere; and also the *Book of Arran*. He was appointed to the Royal Commission on Ancient Monuments of Scotland in 1908 and was a Fellow of the Scottish Society of Antiquaries. He had been a member of the British Medical Association for well over forty years, and served as vice-president of the Section of Anatomy at the Annual Meetings at Oxford (1904) and Sheffield (1908), and president of the Section of Anatomy and Physiology at Birmingham in 1911. His wife, who died in 1934, was an accomplished artist and embroiderer, who worked the beautiful banner for the Glasgow University Memorial Chapel. He is survived by his son, Major W. J. P. Bryce, of Downington, Lechlade, with whom he lived for some of his latter years.

WALTER DANDY, M.D., F.A.C.S.

Dr. Walter Dandy, whose parents came from the Furness district of Lancashire, died suddenly in Baltimore a few days after his 60th birthday and was robbed of the years in which he might have continued to be famous. For a deservedly famous surgeon Dandy surely was. Few men have continued to be so productive into their later years of such good and such new work. His name will always be remembered as the inventor of some of the major technical advances in the surgery of the brain, notably pneumography. By its means the significance of ventricular shifts and of local or general deformities was clarified. Dr. Dandy was well prepared to profit by the powers that this new diagnostic method conferred because his experiments on the secretion, on the circulatory pathways of the cerebrospinal fluid, and on the passage of dyes through it had given him an insight shared till then by scarcely more than his original collaborators, Blackfan and Weed—and to

some extent by Cushing. With increasing experience the third ventricle became an object of special study, and Dandy's books on tumours of the third ventricle (1932) and on benign tumours in the lateral ventricle (1934) are already classics. One of his latest papers (1945) was on strictures of the iter of Sylvius: a review of all the cases that he had gathered during the last 23 years.

It was in the innovation of surgical diagnostic methods and in the development of special techniques appropriate to particular regions of the brain (the ventricles, the pinealomas and other deeply seated tumours) that Dr Dandy excelled his early master, Harvey Cushing, whose assistant he had been in the latter's Johns Hopkins phase, his beginning. No surgeon has ever been bolder than Dandy in his designs (as in excision of the cerebral hemispheres): a boldness usually justified by successes where none had been won before. He was most people thought, a little too contemptuous of the final value of non-surgical diagnostic methods in neurology, nor was he as deeply interested in pathology as many would have wished. Dandy was in these respects very different from Cushing, and no two men could have made such great contributions to the same subject in more different manners. Dandy was always sure of the correctness of his own views and inclined to be contemptuous of opposing ones, but at the same time he was very shy and preferred, if he could, to hold himself aloof.

Walter Dandy had the advantage of association with Max Brödel, who founded the department of medical art at Baltimore, and all Dandy's papers are adorned and given a particular point by illustrations by that master draughtsman or by his pupils. No one made greater use than Dandy of the possibilities of the artist, as all his books and writings testify.

It would be wrong to bid farewell to Dr Dandy without a mention of his work on intracranial aneurysms of all sorts. Here he was again the first to do something—to put a clip upon the neck of an intracranial aneurysm intracranially, or to clip or ligature the carotid itself just after it had pierced the dura.

We mourn the loss of one who in energy, enterprise, imagination and technical ability has not been surpassed.

G J

J O W BLAND, M.D.

John Bland, who recently died at the early age of 46, was one of the small band of highly trained virus workers whose importance is out of all proportion to their numbers. He did particularly good work on the tissue culture of brain tumours and on the aetiology and treatment of trachoma and ophthalmia, and his death in the fullness of his powers is a sad loss to this country. He came of a literary family—his father was a well-known Fabian and his mother was the author Edith Nesbitt—and science and art were curiously blended in him. His handwriting resembled a mediæval manuscript, and he was a keen musician, both as player and listener. He had been a good oarsman at Cambridge, and after qualifying and doing house appointments at St. George's, he returned there to specialize in pathology under Dean. He learned his virus technique under Bedson at the London and tissue culture under Canti at Bart's. Canti died with his photomicrographic studies uncompleted and Bland seemed the likely man to succeed him, but a serious chest illness in 1937 changed his plans and he took up a research post in Egypt. Before leaving England he acted as secretary of the Section of Pathology, Bacteriology, and Immunology at the Plymouth Annual Meeting of the B.M.A. in 1938. He spent six happy and fruitful years in Cairo, which was soon to be the hub of the Allied defence system. In a subtropical climate, in which eggs always seemed to be spontaneously infected and tissue cultures were difficult to maintain, he worked steadily at trachoma and blindness, and gave much of his leisure time to civil defence. A succession of soldiers and pathologists enjoyed the hospitality and the musical Sundays at the Blands' flat at Zamalek, but only the pathologists realized that the exquisite design on the screen in the lounge was an enlargement of the growing edge of one of John's tissue cultures.

Much as he loved the white sunshine and the keen air of the desert, they proved less favourable to his malady than had been hoped. The relative isolation in which he worked also bore heavily on his spirit, for he was a man who found a great stimulus in the exchange of ideas with fellow workers. His health broke down again, and he was forced to return home. In a last letter, written

lying in his garden in Sussex, he wrote that never had the spring seemed so green and lush and beautiful. It may well be that his sense of beauty, was sharpened by his forebodings, for shortly afterwards the end came with surprising suddenness. A former colleague in a message of condolence spoke of his kindness and gentleness. To these one would add the virtue of graciousness. In these days of harsh uniformity it is good to be reminded that our profession still provides a framework within which men can satisfy their scientific and artistic sensibilities and can display those vital differences which make them an object of interest and affection to those who have the good fortune to be called their friends.

L J W

H E COUNSELL, F.R.C.S.

Dr Herbert Edward Counsell, who died at his home in Pusey Street, St. Giles, Oxford, on May 4 at the age of 83, had joined the B.M.A. in 1887 and was secretary of the Section of Surgery at the Annual Meeting at Oxford in 1904. He resigned from membership in 1931, some years after losing the sight of both eyes from glaucoma. He had been for many years one of the best loved figures in the University and town, and after his affliction the many visitors to his house were scarcely conscious of talking to a blind man. Born in 1863 at Chepstow, he studied medicine at Guy's Hospital, qualified in 1884, and some years after serving as resident obstetric officer at Guy's took the F.R.C.S. Always a lover of the country, Dr Counsell chose general practice to a career at Guy's which seemed open to him, and worked for ten very happy years at Liss in Hampshire. It was by chance that he made the move to Oxford. He visited a sister, then a student at the University, in glorious summer weather, and the beautiful city cast its spell over him. He disposed of the Liss practice and put up his plate at a house in the northern academic suburb of Oxford. There was no immediate response, but success came, not only did he become prominent in his profession but also a considerable figure in University and city life. At the age of 40 he entered New College and graduated with second-class honours in modern history in 1906. The Oxford University Dramatic Society had in Dr Counsell a staunch supporter and a warm friend of all the members. After the first world war the O.U.D.S. was nothing more than a tradition, but he directed his energies to its successful revival. A short time ago he published a book of memoirs under the title *37, The Broad*, the old house in Broad Street where he lived for many years. It had an enthusiastic reception for everyone who knew Dr Counsell felt that his was a life that should be recorded.

Dr B.S. writes: There must be innumerable people, literally all over the world and from all classes of society, who will feel that they have lost a personal friend in Dr H. E. Counsell. He was one of the last of the great Oxford "characters"—known as "Dogs"—to countless friends both inside and outside the University. For a number of years he had the biggest general practice in Oxford, and he would have been able to retire with a considerable competence had he only been willing to send in bills. Nevertheless, whereas anyone could be sure of profiting by his professional advice, it was very difficult to persuade him to charge proper fees. He was a gifted surgeon, but it is fortunate in a way that circumstances directed him into general practice, which enabled him to use his very remarkable personality to the best advantage. He was a natural "psychologist," who knew exactly the right thing to say at any given moment, for he used his heart as well as his head. In addition to his professional attainments, he was an excellent historian and a man of wide culture. The present writer was in the habit, year after year of spending his summer holidays with "Dogs" and his family, wandering all over Europe with a rucksack. He looks back on these holidays as being among the most "educative" as well as the most delightful souvenirs. In 1943 he published a book called *37 The Broad: The Memoirs of an Oxford Doctor*. This gives a better idea of the man than could any outside account. Unfortunately the book was sold out within a very short time of publication. It is hoped that it may be possible to arrange for a memorial edition.

The last twelve years of his life were clouded by what would have been for men of lesser calibre a major tragedy—name-blindness. No one ever heard him complain. He just set to and learnt typing and Braille. In fact, he himself typed the whole of his book, which ended with the words: "Surely Thy goodness and loving kindness have followed me all the days of my life."

Dr. JOHN BASIL, who died on May 13, earned for 27 years the heaviest practice in one of the most populous districts of London—Bermondsey. Proud of his mission, he administered with zeal his help to all his patients and often had to visit some

who lived as far even as Purley and Putney. By day and night he never refused to answer a call even during the worst period of the blitz. Taken suddenly ill with coronary thrombosis nearly six months ago, he was then admitted into Guy's, and three months later, feeling better, in spite of all admonitions, he returned to his work. But after two months a second attack supervened and he died with agonizing dyspnoea which lasted 11 days. Dr. Basil was an Armenian, and though he came to this country at the age of 23 to join his brother, who was a clergyman of a Protestant church, and to avoid the persecution of the Turks, he had already served as professor of Turkish at Marash, Syria. Having studied medicine at St. Thomas's, King's, and Charing Cross Hospitals he qualified in 1918. I well remember him, a few weeks before then, coming one morning after a sleepless night to show me a letter from the War Office informing him with regret that all his relations in Turkey, together with many other Armenians, were burned alive in a forest. Under such trying circumstances he had to concentrate his mind on his final examination. With the makings of a Christian missionary in him he then settled in Bermondsey convinced that the proudest mission of man was to serve humanity. Simple yet dignified, kind and patient, he soon gained the confidence and gratitude of all who came near him.—J. P.

ERNEST CHITTENDEN BRIDGES, who died recently in South Kensington in the neighbourhood where he had practised for a lifetime, was born in 1868 at Ipswich, the fifth son of John H. Bridges. He studied medicine at St. Bartholomew's Hospital, whence he qualified as M.R.C.S., L.R.C.P. in 1891, and later became M.D. Durham. He served St. Bartholomew's as house-physician, and was also house-surgeon at the Royal Northern Hospital and house-physician at the Brompton Hospital for Consumption. Settling in practice in Kensington in conjunction with the late Sir Robert Fox-Symons, he had the misfortune early in his professional career to contract pulmonary tuberculosis; from this he made a good recovery, but his energies thenceforth had to be carefully conserved. He was medical officer to St. Dunstan's Hospital for over 30 years, and served for a similar period on the staff of the Margaret Street Hospital for Diseases of the Chest, where he became ultimately consulting physician. But it will be less for these distinctions than for his personal qualities that he will be best remembered by his patients and his professional colleagues. Bridges—often affectionately known as "Briggs" by his friends—was a man of handsome features and manly frame who knew his job as a general practitioner "inside out"; always reliable, always kind, always honest and honourable, and with it all both human and humorous. Very definitely a personality and a credit to his profession, he will not soon be forgotten in South Kensington. He married twice; there was no issue of either marriage. For the last three or four years Bridges had been missing from the committee meetings of the Royal Medical Benevolent Fund, to which he had rendered long service, and from his club; a long series of illnesses and accidents had made him a chronic invalid, but his cheerful and indomitable rage sustained him to the end.—H. R.

he death last April of ERNEST CLARKSON BOURDAS deprives e Balham and Streatham districts of South London of a very senior practitioner, for he settled there immediately after filling his resident appointments soon after qualification. He was born in 1874, the son of the late Mr. I. Bourdas, and was educated at St. Paul's School and the Medical School of St. Thomas's Hospital. Qualifying as M.R.C.S., L.R.C.P. in 1899, he took the Brussels M.D. in 1900 and the Edinburgh F.R.C.S. in 1901, having meanwhile been house-surgeon at his own hospital. In the 1914-18 war he was a temporary captain in the R.A.M.C. and was employed as surgical specialist at the hospital at Frensham Hill. He remained in practice up to very shortly before his death, refusing to retire when normally he could have done, owing to his patriotic desire to do all he could for the Allied cause. This resulted in much overwork and definite overstrain, and probably brought about his breakdown in health, for although of impressive physique he was not overstrong constitutionally. Dr. Bourdas is survived by his widow with one son and one daughter: his brother is a retired surgeon captain in the Royal Navy.

The untimely death of ARTHUR WESSON, M.D., F.R.C.P., F.R.C.S., has removed a personality of great charm, ability, and enthusiasm, and it has dealt a bitter blow to the young specialty—physical medicine—which owes him so much. He came to University College Hospital from Merchant Taylors' in 1921, and after the usual resident appointment went to the Queen's Hospital, Birmingham, as R.M.O., later returning to U.C.H. in the same capacity. A travelling scholarship took him to America and Sweden. By now his interest was in arthritis and the then neglected specialty of physical medicine.

He returned to the L.C.C. at Mile End Hospital and in due course became deputy medical superintendent. When his own hospital decided to raise the charge of the physical medicine department to the status of an honorary staff post Wesson was appointed. At U.C.H. Wesson had just time before the war to organize a department which was unexcelled by any other hospital. But his main contribution was to the R.A.M.C., where in the early days of the war he took medical charge of the first physical development centre and later of rehabilitation in B.N.A.F. It was on his return from Italy that he contracted the illness which killed him, but his report on his work in that theatre of war will remain as a blue-print for any future campaigns. Wesson was essentially a team-worker. He effaced himself to a remarkable degree in securing the co-operation and co-ordination of all his colleagues, both medical and auxiliary, for he realized most clearly that therein lay the key to successful rehabilitation. His cheerfulness and unfailingly happy approach sometimes obscured his considerable width of knowledge—for he was a Fellow of both Colleges—but it secured the devotion of the physiotherapists and physical training instructors whom he delighted to teach, and of his patients who received every ounce of his energy.—F. D. H.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

R. R. A. Coombs, B.Sc.Ed., of Trinity Hall, has been elected into the John Lucas Walker Studentship from Oct. 1, on the nomination of the Professor of Pathology.

At a Congregation held on May 18 the following medical degrees were conferred:

M.D.—E. V. Bevan, S. R. F. Whittaker, J. D. Fergusson, D. Russell-Davis, N. C. Oswald, J. S. Minnett, *H. E. W. Robertson, *D. A. Smith.
M.B., B.Chir.—*S. R. Mawson, *A. L. T. Easton, *W. H. Davies, *R. I. Milne, *N. K. Dryden.

* By proxy.

UNIVERSITY OF LONDON

Sir Ernest Graham-Little, M.D., F.R.C.P., M.P., has been re-elected to represent medical graduates of convocation upon the Senate of London University; Sir Archibald Gray, M.D., F.R.C.P., and Mr. John B. Hunter, M.Ch., F.R.C.S., have been appointed to represent the Faculty of Medicine; and Dr. H. E. A. Boldero, F.R.C.P., the general medical schools.

The University has gratefully accepted an offer from the trustees of the estate of the late Sir Henry Wellcome of a capital sum of £74,000, for the endowment of the chair of pharmacology tenable at the College of the Pharmaceutical Society, and henceforth to be entitled the Wellcome Chair of Pharmacology. The income will be used to pay the salary of the holder of the chair, now occupied by Prof. G. H. Buttle, and to contribute to the cost of his research work. The Department of Pharmacology at the College was founded in 1926 and has made important contributions to research and teaching in pharmacology and physiology. It is hoped that, with the funds now provided, the activities of the department will be maintained and expanded.

Prof. A. J. E. Cave, M.D., has been appointed to the university chair of anatomy tenable at St. Bartholomew's Hospital Medical College from May 1, and Dr. J. N. Davidson has been appointed to the chair of biochemistry tenable at St. Thomas's Hospital Medical School from April 1.

The title of Professor of Medical Protozoology in the University of London has been conferred on Dr. H. E. Shortt in respect of the post now held by him at the London School of Hygiene and Tropical Medicine.

UNIVERSITY OF SHEFFIELD

At a meeting of the University Council, held on May 17, the following appointments were made: *Part-time Tutors in Surgery*, E. P. Hall-Drake, F.R.C.S., and C. D. P. Jones, F.R.C.S. *Part-time Tutor in Obstetrics*, H. J. Green, F.R.C.S.Ed., M.R.C.O.G. *Part-time Assistant Tutor in Obstetrics*, W. J. McCord, M.D., M.R.C.O.G.

The Council received the resignations of Prof. G. A. Clark from the Chair of Physiology on taking up a post in the Ministry of Health, and of Dr. Ethel M. Spedding from the post of temporary demonstrator in anatomy.

UNIVERSITY OF ABERDEEN

Dr. D. R. MacCalman has been appointed to the newly founded professorship of mental health in the University of Aberdeen. This is the third chair of the kind to be instituted in Great Britain, and it has been done in co-operation with the local authorities and voluntary hospitals. The professor will be physician in charge of psychological cases in the key hospitals of the area, though the administration of the mental hospitals continues as before.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The Health Service Bill

A meeting of Fellows was held on May 8, when the President Sir Alfred Webb-Johnson, after reporting on College affairs, said the Council desired to ascertain whether its attitude in regard to the National Health Service Bill was such as to have the approval of the Fellows in general. The Council concurred with the observations of the Negotiating Committee and gave the committee full support. The attitude of the Negotiating Committee was well known, and the basis on which objections were made to some features of the Bill was that some of the proposals were regarded as a threat to the freedom of the profession; for example, the prohibition of the sale and purchase of practices. The attitude of the Council was that if there was freedom of choice for the citizen in seeking professional advice, practices were transferred to the practitioner whether the member of the profession was paid directly by the patient or indirectly out of the Insurance Fund or by the State. The good will was therefore an original asset of that member of the profession and, if the sale of practices was made illegal or otherwise rendered ineffective, adequate compensation should be paid. The Council regarded with misgiving the setting up of a tribunal appointed by the Minister which could prevent a man from receiving public patients although he might remain on the Medical Register. It objected to the requirement to obtain permission to practise in a district, and saw great dangers in a substantial part of the general practitioner's remuneration being in the form of a salary. With regard to specialist practice, it feared that the Government proposals as a whole amounted to a Government monopoly of all hospitals, which practically implied that it was illegal to set up any independent hospital in the future, and the power which the Minister sought to obtain to acquire by compulsion purchase any institution for the treatment of patients, whether run for private gain or not, gave him the power to prevent a specialist earning his living, because the background of his living was an equipped institution. It was also a great anxiety to the Council that these proposals were only a stepping-stone towards a whole time salaried service. There would be a disturbance even in the first instance of the doctor-patient relationship if part of the doctor's remuneration came from salary. Other points which had caused the Council grave concern were the interference with voluntary effort, the appointment of bodies with very great powers who would be appointed directly by the Minister and not elected by the people, and the interference with hospital trusts. These considerations had led the Council to pass a number of resolutions which were before the meeting.

After general discussion Mr T B Lavton moved a resolution that the meeting should give general support to the Council in the action it was taking, and this was carried unanimously.

Mr Charles L Mayer of New York has made a further award for the encouragement of British scientists and surgeons. A few months ago he gave £1,000 to the Royal College of Surgeons as a prize for Mr Terence Millin for his contribution to the advancement of the surgical treatment of enlargement of the prostate. He has now made a gift to the College of £1,000 as a prize for Prof E C Dodds, FRS, in recognition of his work in discovering and studying stilboestrol, and as an encouragement to him to continue his researches in the field of the synthesizing of hormones. The award will be presented to Prof Dodds on June 13.

The following lectures will be delivered at the College (Lincoln's Inn Fields, WC) at 5 p.m. on each day.

Hunterian Lectures—June 6, Prof D S Poole Wilson, *Missile Injuries of the Urethra*; June 13, Prof J D Ferrarsson, *Original Observations in Carcinoma of the Prostate Treated with Oestrogens*. *Lectures by the Research Professor in Ophthalmology* (Prof Arnold Sorsby)—June 20, *Pure Penicillin in Ophthalmology*; June 27, *Genetic Aspects of Ophthalmology*.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

At a meeting of the College held on May 7, with the President, Dr D M Lyon, in the chair, Drs T Carlyle Mitchell and O Olbrich were introduced and took their seats as Fellows of the College. Drs A H Campbell, N G Pandala, N F Lilawala, G O Horne, and S G Graham were elected Fellows of the College.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the Royal College of Surgeons of Edinburgh held on May 16, with Mr James M Graham, President, in the chair, the following candidates who had passed the requisite examinations were admitted Fellows:

H. M. Bradmore, A. El Marn, A. A. Finlayson, A. L. Goodall, R. S. Hunt, R. R. Hunter, W. C. Lawrence, B. Lawson, K. Mack, Leitch, D. M. N. Loring, W. Magauran, K. S. Masalawala, N. R. K. Mitchell, Mary G. Murphy, I. W. J. McAdair, L. R. Rabson, D. R. Ryder, R. S. Stewart, E. B. Tovey.

The Henry Arthur Dalziel Ferns Bursary was, after a competitive examination in organic chemistry in its application to medicine, awarded to I. S. Trotter.

Medical Notes in Parliament

HEALTH SERVICE BILL

When discussion of the National Health Service Bill was resumed in a Standing Committee of the House of Commons on May 21, Mr Bowles again in the chair, consideration of Clause 4 was begun. In the provision that "the Minister may make certain accommodation in hospitals which is not for the time being needed by any patient on medical grounds available for patients who undertake to pay," Mr REID moved to substitute "shall" for "may." He said that if accommodation existed which was not needed on medical grounds there should be no question of Ministerial discretion. Something could be said for leaving a discretion with a hospital management committee or board of governors. Mr BEVAN replied that in practice the decision whether an individual case went there or there would be entirely a matter for the local hospital authorities to determine but the Minister must have a power of veto for the accommodation as a whole. The Government had gone further in provision of beds available on part-payment than many on his side of the House desired, and he was not prepared to extend the power already given. The amendment was withdrawn.

Mr MESSER moved to leave out the proviso "on medical grounds" because there were other conditions which made it inadvisable for a patient to be in the same ward as other patients. On Mr BEVAN's assurance that the word "medical" would cover all the situations Mr Messer had in mind the amendment was withdrawn.

On the motion that Clause 4 stand part of the Bill Mr SOMERVILLE HASTINGS pointed to the difference between Clauses 4 and 5, in Clause 4 only part of the charge was recoverable whereas in Clause 5 (1) the whole charge was recoverable. Mr BEVAN said Clause 4 referred to accommodation which might be made available in a hospital. Clause 5 referred to separate accommodation, in a pay block expenses were greater and the Ministry wanted power to recover them. Dr MEDFORD TAYLOR asked whether in a case under Clause 4 no medical fees could be recovered from persons who paid for special accommodation. Mr BEVAN said medical fees could be recovered in certain circumstances because some hospitals might have no pay block. The Clause was approved.

PAY-BED ACCOMMODATION

On Clause 5 (Accommodation for private patients) Mr REID moved to substitute "If the Minister is so advised by the Regional Hospital Board, he shall" for the words "If the Minister is satisfied that it is reasonable so to do, he may." He said that this was obviously a decision which must be taken on a district or at most on a regional basis, having regard to the accommodation and services available. It could not be determined by the local hospital committee. Mr BEVAN said it would be a reversal of the whole procedure under the Bill to make the Minister the instrument of the Regional Board. Mr Reid's words suggested the Minister would be bound to do what the Regional Board advised. The Minister would normally receive the advice of the Regional Board on what accommodation should be set aside, but it must be the Minister who, in the light of the relations between Regional Boards must ultimately decide on the scheme submitted. The Ministry of Health had proposed pay-bed accommodation not only because there must be diversification of services inside the National Health Service but also because the Government desired the association of specialists with the hospital. Unless there were pay beds they might not come to the hospitals; therefore there was no danger that pay beds would not be provided. The amendment was withdrawn.

Mr MESSER moved to leave out the word "urgently" from the proviso that nothing in subsection 1 of the Clause about accommodation for private patients should prevent that accommodation from being made available for anyone who urgently needed it on medical grounds and for whom suitable accommodation was not otherwise available. Mr BEVAN said it would be difficult to administer a hospital if the management committee had not reasonable security for some of the pay beds provided. In the case of the pay blocks it was implicit between the Regional Boards and the specialists using the pay blocks that there should be a firm contract. The specialist would have made available to him a certain amount of accommodation in a separate wing. If that were open to be assailed at any moment on the same grounds as pay beds the specialist would not know where he stood.

Dr BARNETT STROSS thought the word "urgently" might act partially against the majority of people. The provision was already qualified by the words "on medical grounds" and

might safely be left to the discretion of the matron or hospital board. Mr. Messer withdrew the amendment.

SPECIALISTS' PRIVATE PATIENTS

Mr. MESSER then moved to omit subsection 2 of Clause 5, under which the Minister can allow any specialist on the staff of a hospital providing hospital and specialist services to make arrangements for the treatment of his private patients either at that hospital or at any other such hospital. He said the Minister was taking over voluntary hospitals which had been used by specialists for the treatment of their own cases. The hospitals would be public property and the specialists would be paid from the public purse. There was a grave danger in specialists, who might be servants of the State, being entitled to treat their patients privately and being paid by those patients for that service. He foresaw better treatment for those who could afford to pay for it.

Mr. SOMERVILLE HASTINGS said he was sure no doctor did a better operation for private patients than for ordinary patients, but he was sure that they gave more personal attention to the private patients and left more to the house-surgeons and registrars in the case of the other patients. When these hospitals came under State control everyone would have a right to treatment in them. Why should anyone wish to pay the doctor unless he expected to get better treatment by so doing? The Committee was making the individual who received the payment the arbiter whether beds should be used for patients for whom payment was received. Mrs. BRADDOCK said that a part-time specialist service would be what the country would have to use for the time being. While that existed Parliament must allow part-time specialists to charge a fee. If the specialist was paid a full-time salary he had no right to charge a private patient; the Clause might need some alteration to fit that position.

Dr. TAYLOR hoped that in the side wards fees would not be charged because otherwise appalling abuses would be liable to arise. Everyone who had worked as a hospital administrator had seen from the inside the difficulties which continuously arose when the specialist's pocket pulled against his good judgment. In this Clause Mr. Bevan not merely was giving the specialists what they wanted in private accommodation but would subsidize their activities. If the patient was in a private ward and needed a blood count or an x-ray examination he would still be entitled to that service under the Bill. Labour Members did not like this arrangement but accepted it reluctantly as a necessity of the situation. The way to overcome the problem was to make full-time hospital practice so attractive that every specialist elected to become a full-time hospital specialist.

Dr. MORGAN said his experience of both general practitioners and specialists was that their standard of conduct and ethics was as high as that in any other section of the community—certainly as high as that among trade unionists or M.P.s. The part-time specialist must be given a concession of this kind, and Dr. Morgan saw nothing which would tempt the specialist to do something which would be regarded as unethical.

A FULL-TIME SALARIED SERVICE OF SPECIALISTS

In reply to Sir Lucas Tooth, Mr. BEVAN said the patient himself would determine whether he was a private patient. If he wished to insist upon selection of a doctor he would become a private patient. He (Mr. Bevan) admitted that specialists were being given favourable treatment, but he believed that by this means Parliament would eventually obtain a far higher standard of service. Radiological examinations, blood counts, and all the other facilities of a hospital would be available to a patient free, and therefore the Committee was not favouring a patient by not charging him for them if he himself was paying for a specialist. No additional facilities were being given. But what the Committee must try to procure was that the specialist was induced so far as possible to spend all his time at the hospital, both for his own sake and, in the case of the teaching hospitals, for the sake of the students and for the whole atmosphere of the hospital. It would be disastrous if there grew up in Great Britain a rash of nursing-homes where the specialist intellectually isolated himself and where the patients would not get the same standard of treatment. Unless the Committee agreed to the subsection that situation would arise, and not only in this country. In the past the *prima donnas* of the medical profession had influenced administrative policy because they could use their influence to attract money for the hospitals. In future the financial pulling-power of the medical *prima donna* would no longer be necessary to the hospitals. Replying to Mr. Somerville Hastings Mr. BEVAN said that the attraction of funds would also disappear in the case of the teaching hospitals, which had had bitter experiences of theoretically possessing a specialist on their staff who was not available for general hospital purposes. In future a hospital would not have to placate the idiosyncrasies of a specialist to build up its own

patients and to find its revenues. He had made special efforts to enable the specialist to attend patients in several hospitals. There was a lot of intellectual in-breeding in some big teaching hospitals. The specialist would be in contract with the Regional Board, and would move quite freely throughout the whole of the system. The necessity for the specialist to have continuous care of the patients he treated must not undermine the principle of mobility within the service. The specialists were in contact with the Regional Boards and in contact with teaching hospitals. He hoped to make arrangements with the teaching hospitals whereby the specialists attached to a teaching hospital would not spend all their time there. By spreading the specialist over the hospitals the Ministry was limiting the possibility of abuse. The whole momentum of the scheme would be in the direction of a full-time salaried service for specialists at hospitals.

Sir H. MORRIS-JONES: That is what we are afraid of.

Mr. BEVAN said at present many young men from the Forces would be in a better position if this scheme were in operation and the Ministry could use their services immediately. The Ministry wished the apparatus it was providing to be used by the medical profession in the freest possible professional manner, but it wished to secure that the administration of the hospital itself was, so far as possible, in secular hands.

Mr. Messer withdrew his amendment.

G.P.'S PRIVATE PATIENTS

Mr. Linstead moved to insert additional words to subsection 2 which would grant the same facilities [for treatment of private patients] to "any medical practitioner providing general medical services in the area of any hospital." The intention of the amendment was to ensure that general practitioner beds should be available at hospitals. Col. STODDART-SCOTT said that Mr. Bevan himself during the Committee Debate on May 16 had conceded it to be vital that general practitioners should be encouraged to visit their patients in hospitals. Mr. BEVAN said that presumably these patients were entitled to free hospital services; and they could afford, or for some reason wished to acquire, private accommodation in a general practitioner hospital. He hoped that a general practitioner would have access to his patients in every hospital; he would not charge hospital fees because it would be a private patient and he would be charging general practitioner fees. On the other hand the patient would pay for the bed and would have the general hospital service free. Therefore the Ministry was not interested whether the patient was paying the general practitioner. If the patient was on the general practitioner's list then the doctor could not accept the fee, but if the general practitioner had a patient who was paying a private fee that practitioner could treat his patient in the hospital in the same way as he could treat his free patients. The Ministry encouraged the general practitioner to have these facilities, and Mr. Bevan understood that they were available. In a general practitioner hospital where no specialist's services were required a general practitioner would normally be in charge of his patient and would prescribe the treatment. Where the patient was in the hospital under a specialist the relationship between the specialist and the general practitioner was a matter for the hierarchy. It was a fact that there were some hospitals from which the general practitioner had been barred in the past. He wanted to make it clear that the general practitioner should give treatment in a general practitioner hospital to persons who could not get treatment at home but suffered from something that did not require specialist treatment. He would consider whether it was necessary to put down an amendment to make that clear. The amendment was withdrawn.

Mr. HENRY STRAUSS moved to leave out the words which enabled the Minister to prescribe regulations fixing the maximum charges to be recovered by specialists for treatment of private patients. He supposed the idea of the words was to secure some limitation of maximum income for the surgeon. His own view was that that was not good sense and not even good socialism. The Minister had made it clear that he wished to get as many specialists into the National Service as possible. The Minister was putting strong pressure on the specialist to come into the scheme, otherwise the specialist could not get his patient into the hospital. Why then should the Minister deprive first-rate men of first-rate prizes?

Mr. BEVAN said he would like to warn Members that if long polemical speeches were made on Committee points the Committee would not be able to get the Bill through on its time schedule. The Committee adjourned.

On May 22 Mr. HOPKIN MORRIS, resuming the discussion of Mr. Strauss's amendment to Clause 5, said that if the words which Mr. Strauss proposed to omit were retained they would defeat the aim of the Minister. His aim was to bring private patients into the State hospitals, but the words now challenged would drive them out. Mr. BEVAN replied that if he thought

he Clause would drive specialists away from the State hospitals into private nursing-homes he would accept the amendment, but he did not think that that would be the effect. It was reasonable that the Ministry should seek to protect patients against exorbitant fees for operations to be performed in State hospitals with State facilities. He thought that the "ceilings" would probably be fixed fairly high as they now were in many hospitals, and very good incomes would be obtained under them. He was not capable of stating what would be reasonable fees for different operations by different specialists and he did not propose to try; there would be a range of fees with a maximum. The amendment was negatived.

A SAFEGUARD FOR THE PUBLIC

Col. STODDART-SCOTT moved to add at the end of the subsection a provision that the Minister

"shall allow any specialist to make arrangements on similar terms with the Hospital Management Committee or Board of Governors constituted under the following provisions of this part of this Act or the treatment of his private patients at any hospital for which such Committee or Board are responsible."

He said this proposed that any specialist, even those outside the scheme, should have the use of the national services and be able to make arrangements to send their patients into the hospitals so that the patients might have the inalienable right to the hospital beds and the specialists' services. This was not to the benefit of any individual consultant or specialist but so that the people could have some safeguard. The desire of the people for an independent opinion from a specialist not in the Government service would still exist—for example, in war pension cases and industrial injuries. Sir H. MORRIS-JONES said Mr. BEVAN could not expect to get every consultant and specialist in the kingdom into the scheme straight away; the scheme would ostracize a number of reputable medical men in this country. Mr. LINSTED, supporting the amendment, thought it should not cut from the Minister that freedom of choice of doctor and freedom of choice of hospitals had been rejected. Those two things were regarded as basic principles of the Bill.

Mr. BEVAN said the amendment would provide an inducement to doctors and specialists to remain outside the scheme. They would say, "We can sabotage the service by staying outside and we can always use it if we want to." If the medical profession were more hostile to this scheme than they appeared to be that would be extremely dangerous. A specialist or consultant physician who was not attached to a hospital and did not avail himself of the clinical experience and knowledge which accumulated there would not be the person anyone would wish to consult. As for the argument that people would like to have an independent opinion, the fact was that the doctors would not be employees of the State. They would be under contract to the governing boards of the teaching hospitals and not under contract with the Ministry of Health. They would be perfectly free. They were largely part-time people, and it was absurd to suggest that these highly qualified men with vigour of mind and character would concede for a moment that they would not be able to give a second opinion hostile to the first because the State might be involved in some way. In any case an insignificant number of persons were going to be outside the scheme.

Mr. REID pointed out that Mr. BEVAN had said a specialist must keep in touch with hospital practice. He asked whether Mr. BEVAN would offer these men the opportunity of keeping a substantial part of their time, say half, for private practice. That would influence many specialists. The Committee had not yet heard about the terms on which people were allowed to come in as specialists. Mr. BEVAN replied that so long as a specialist was attached to the public service, no matter in how small a degree, he was conceived to be in that service. There would be no question that he must spend half his time in the hospital; it might be much smaller than that.

The Committee divided and the amendment proposed by Col. Stoddart-Scott was defeated by 28 to 14. Clause 5 was then ordered to stand part of the Bill.

LOCAL OWNERSHIP OF HOSPITALS

On Clause 6 (Transfer of hospitals to the Minister) the chairman, Mr. BOWLES, said he proposed to call two amendments in the names of Mr. Willink and Mr. Reid. The main discussion would turn on the second one.

Mr. LAW moved the first amendment, which provided that the transfer should be made "where on the appointed day the Hospital Management Committee for any voluntary hospital has not been appointed under this Act or such later dates as a Hospital Management Committee shall be so appointed." Since, he said, this amendment was consequential to the second one he intended to address himself to the second, which pro-

posed to leave out the words transferring to and vesting in the Minister all interests in premises forming part of a voluntary hospital, and inserting instead words transferring these interests to "the Hospital Management Committees or the Boards of Governors constituted under the following provisions of this Act." Mr. LAW said that Mr. BEVAN could accept these amendments without losing his main objectives; he would still be able himself to provide the integrated hospital service which he thought was necessary. He would still have the duty to provide the service, responsibility for it would still be on his own shoulders; administration of the hospital service for the region would still be in the hands of the Regional Hospital Board. The hospital premises would not vest in any outside body, but either in the Management Committees appointed by and responsible to the Regional Board or in the Boards of Governors appointed by and responsible to the Minister. The Committee had decided already that responsibility for the regional administration should be with the Regional Board and with the Minister, but it was of the utmost importance that the Management Committees and the Boards of Governors should have the fullest responsibility for the administration of their own local unit.

Mr. BEVAN said the argument here was that the hospitals should cease to be in their existing ownership and should vest in the Management Committees or the Regional Board as the case might be. It would be simpler if all hospital property was vested in the Minister. A time might arise when the Management Committee might be replaced by some other administrative body, bringing the complications of transferring the property to a body which Parliament would have to define. Ownership would not conduce to the authority of the Management Committees under the Regional Boards. What would conduce to their authority and autonomy were the administrative functions which the Minister gave them and the financial flexibility of the whole machine.

Cmdr. MAITLAND said under central financial control there must be some form of central bulk purchase with the Treasury overshadowing the buying. He would prefer local control in these matters. Mrs. MIDDLETON asked for an assurance that where the names of hospitals had a commemorative association those names would be maintained on the transfer of ownership. Mr. BEVAN gave this assurance, saying it was hoped to preserve the identity and names of association of such hospitals.

Mr. REID pressed for an assurance that the Ministry of Works would have nothing to do with the hospitals. He asked whether alterations were to be done by the Regional Board through local architects or by the Ministry of Health through its building section, or through the Ministry of Works. Nothing could be more disastrous for hospital progress than that the Ministry of Works should be the Government's agents. He further inquired whether maintenance of existing buildings would be left to the discretion of the Regional Board or a local committee, and whether it was proposed that transfer of ownership should take place before the new Hospital Committees were in the saddle.

Mr. BEVAN said he could not agree that ownership would carry with it other powers, such as employment of architects. The wide body of knowledge at the disposal of the Ministry of Health with the many technical advisers available was more likely to produce a good hospital design than was a local Management Committee. The idea that when the Ministry of Works stepped in ruin followed was astonishing. Cmdr. Maitland had said he hoped there would be no standardized buying. Mr. BEVAN confessed that he hoped there would be some. The amendment moved by Mr. LAW was defeated by 26 to 17, and the amendment linked with it was not taken.

Mr. KEY moved to insert words to make clear that easements and rights attaching to hospitals and the premises of hospitals were transferred with the premises themselves. An example might be a right of way over adjoining land for approaching a hospital. Dr. MORGAN asked for an assurance that where hospitals or institutions owned land, such as farms, or had houses on land adjacent for the housing of the staff these properties would be transferred. Mr. KEY said the transfer would occur if the properties were for the purpose of running the hospitals. If they were only for the purpose of endowment they were dealt with in Clause 7. The Committee agreed to the amendment.

PREMISES OF TEACHING HOSPITALS

Sir HUGH LUCAS-TOOTH moved to add the words "other than a teaching hospital" in the subsection providing for the transfer to the Minister of premises forming part of a voluntary hospital. His intention was that buildings and equipment now belonging to teaching hospitals should be transferred not to the Ministry but to the new bodies which were to administer the teaching hospitals. There was a genuine feeling within the hospitals that if legal possession of these buildings was taken

away it might be the beginning of the end of their particular identity and a threat to the existence of their particular name. It was common sense to say that responsible boards governing teaching hospitals should be given power to carry out minor structural alterations without consulting Government Departments. If the Minister gave an assurance that the Ministry of Works was not in the Bill that would go some way towards meeting the objection. There would be difficulty in apportioning the buildings and assets of the teaching hospitals so as to transfer to the Minister only that part which was strictly the property of the hospital while leaving the other part to the medical school. Mr. SOMERVILLE HASTINGS said King's College Hospital had been completely rebuilt during the last 30 years, but did not lose its tradition. It had moved from the centre of London to the outside, but the tradition still remained. Whoever might own these hospitals their identity would continue as long as their teaching schools remained and as long as the tradition remained. The hospitals would lose nothing by being taken over by the Minister.

Mr. BEVAN said he had devised a scheme for administration of teaching hospitals which would leave them with the utmost economy consistent with the general hospital service. He believed the scheme commended itself to practically all the teaching hospitals. Some persons connected with these hospitals had apprehensions which were not based upon facts. Mr. Linstead said he and other members had received a letter from the Voluntary Teaching Hospitals Association saying that the amendments before the Committee were essential for the smooth and efficient working of the proposed service. That letter was dated May 2. Mr. BEVAN said he had been under the impression that the scheme in the Bill was highly satisfactory to the teaching hospitals. Transfer to the Ministry would not make St. Thomas's any less St. Thomas's, Bart's any less Bart's, or Guy's any less Guy's. Their identity and continuity of tradition would be unbroken. They would be enlarged and on much firmer foundations. Furthermore, the Ministry wished power to create new teaching hospitals. It had been suggested that under the Bill the Board of Governors could not spend money on structural alterations, but Clause 12 gave them power to maintain any premises forming part of or used in connexion with the hospital. That included making structural alterations. There would be a global budget, and within that budget teaching hospitals would be expected to discharge those responsibilities. If pressure came from the teaching hospitals to enlarge what they had it might be easier for him (the Minister) to yield to pressure from other directions to take away from them something they had already got. If the hospitals insisted on certain modifications in their direction to get their consent, other modifications might be made to get greater enthusiasm for this scheme from other quarters. He asked whether the teaching hospitals would prefer to own their buildings and have the obligation put on them to spend their endowments on capital expenditure. Most of the endowments which had been given to teaching hospitals were provided for general hospital purposes. They amounted to a sum in the region of £11,000,000. In the Bill he accepted the obligation of maintaining the buildings and of adding more buildings when needed, leaving this £11,000,000 to the teaching hospitals. The amendment was defeated by 25 to 17.

LIABILITIES OF HOSPITALS

Mr. KEY moved to leave out the phrase in Clause 6, subsection 1, dealing with the transfer to the Minister of all liabilities to which the governing body of a voluntary hospital is subject immediately before the appointed day and to insert "rights and liabilities to which any such governing body or trustees were entitled or subject immediately before the appointed day, being rights and liabilities acquired or incurred solely for the purposes of managing any such premises or property as aforesaid or otherwise carrying on the business of the hospital or any part thereof, but not including any endowments within the meaning of the next following section or any rights or liabilities transferred under that section."

Mr. KEY said the amendment amounted to this, that on the appointed day the hospitals would be taken over as running concerns. Contractual rights which had been made with suppliers of goods, drugs, fuel, and so on would be included with the liabilities. The amendment would not apply to some rights acquired by the management of the hospitals under some covenant to pay a yearly sum by way of endowments—that is, it would not apply to endowments within the meaning of Clause 7.

Mr. REID said that under the Bill, as introduced, rights under gratuity covenants would have lapsed because the latter were covenants to pay a voluntary hospital. He thought a court of law would hold that the covenant fell because the foundation of it was abolished by this Bill. If that was so the Minister was really resuscitating these covenants for the benefit of the

Exchequer, because the greater part of the purposes for which the endowments fund would be used were purposes for which the Exchequer would have to pay if there were no endowments. He did not see why someone who wished to support a local hospital should now be told that he had to support a fund which applied to the whole country. This would be so whether Clause 7 (Endowments of voluntary hospitals) was carried or not. Mr. BEVAN said it would be appropriate to raise that point on Clause 7. All the Committee was doing at present was tidying up the Bill to make certain that the running contracts of the hospitals were carried over. The amendment was agreed to.

Sir HAROLD WEBB moved to leave out words in Clause 6 subsection 2, which transferred local authority hospitals to the Minister. He said these hospitals were already publicly owned, and the purpose of a transfer must be to remove them from the control, administration, and direction of local authorities. Mr. BEVAN said the principle of transfer had already been determined and could not be varied in the case of local authority hospitals. The amendment was negatived.

Further drafting amendments were made on the motion of Mr. KEY. By one of these provision was made so that property owned by a visiting committee should be transferred at the same time as the property and liabilities of the local authority. He said that at present visiting committees of mental hospitals took charge of funds and undertook liabilities in connexion with a mental hospital owned by and run by a local authority or a joint board.

Mr. Linstead moved to insert words to provide that the Minister could also decide not to take over a hospital where it appeared to him that its transfer was inexpedient on the grounds that provision of medical services or the services of specialists was not the main purpose of such hospitals. Mr. BEVAN said although "hospital" was defined in the Bill, the kind of institution to be taken over would largely depend upon the recommendations of the Regional Boards and the ultimate hospital plan. It was not intended to take over institutions which were not specifically hospitals or ancillary to hospitals. Mr. Linstead said he was thinking of Papworth, for tuberculosis patients. Mr. BEVAN said that was really a hospital. Mr. Linstead cited homes for the dying and homes for the incurables. In his constituency incurables did not go to one well-known home for medical attention, but to spend their last years and for nursing services. Mr. BEVAN said if the institution were not required for general purposes it would not be taken over. In some cases it might be in the interests of the inmates and those responsible for the institution that it should be taken over. He would not like to be pressed to exclude institutions of that sort.

Mr. MESSER said the Registered Hospitals Association covered some 13 hospitals which specialized in certain cases, and there was no question of any loss of revenue. One of them was St. Andrew's Hospital at Northampton, where especially valuable work was done. He could not find any way of fitting it into the general scheme. Dr. MORGAN cited the Roffey Park Rehabilitation Centre, which was run privately, the Homoeopathic Hospital, and the Jewish Maternity Hospital. Mr. BEVAN asked members not to press the case of those special hospitals at the moment. There was provision for arbitration in Clause 9 of the Bill. The powers of the Bill were wide enough. If the special-hospitals were taken over that would be done because the services they rendered were necessary in the general hospitals service. There was no reason why the Regional Boards should not administer them for national purposes. Mr. Linstead withdrew his amendment. The Committee then adjourned.

TRANSFER OF PROPERTY

Resuming on May 23 discussion of Clause 6, Mr. J. S. C. REID moved an amendment to subsection 4, which provides that all property transferred to the Minister shall vest in him free of any trust existing on the appointed day. The subsection goes on to provide that the Minister may use such property for any of his functions under the Bill, but shall so far as practicable secure that the objects for which the property is used immediately before the appointed day are not prejudiced. Mr. Reid moved to substitute for the latter provision the words:

"But the Minister shall use any such property for the purpose for which it was used or within the district in which it was situated immediately before the appointed day unless the Minister shall be satisfied on the advice of the Regional Hospital Board and of the Central Council that there is no need for hospital accommodation to be provided for that purpose or within that district."

The Opposition agreed that there ought to be some change from the existing position with regard to both buildings and property, but thought that diversion of property from its original use and purpose should be under more precise limits.

In his proposed amendment Mr. Reid would not object if the reference to the Central Council were omitted. The Minister would have power to consult the Council in the case of large national endowments, but in general the Regional Boards ought to be consulted.

Mr. KEY said the amendments restricted the value of the first three lines of the subsection, which transferred the property to the Minister free of any trust. The Government desired that there should be freedom to use property for the purpose of working out a hospital system which would be to the general benefit of the particular district in which the hospitals were situated. The trust mentioned might involve that a particular institution should be used only for patients from a particular district or only to give a certain type of service. In the development of a full hospital system it might well be that institutions were given a definite function, and this might be other than that put down in the particular title deeds. The Government desired that the wishes of the donors should be followed "so far as practicable," and that was provided in the Bill. These matters of detailed administration were not subjects on which the advice of the Central Council could be sought. The Regional Hospital Boards would be the instruments through which the service was to be developed in any area. The Government could not accept the amendment.

Mr. Linstead said the clause was a basic interference by the Government in the freedom of the citizen to dispose of his property in his own way. There seemed to be nothing in the Bill to prevent the Minister selling property and applying the proceeds of the sale in a different part of the country. Mr. Messer said if the amendment were carried it would mean that the orthopaedic hospital at Stanmore must continue to treat nothing but orthopaedic cases, and that the sanatorium at Harefield, not far away, would come within the region but could not transfer to Stanmore any cases other than orthopaedic cases. A lot of orthopaedic work concerned children, for whom there were hospital schools. Under the amendment it might be possible to bring children to Stanmore Hospital and Harefield Sanatorium, but at neither place would the children get the education they would receive if the work were co-ordinated.

Mr. KEY said that in a given area there would be a number of institutions which would come under one hospital committee or would certainly be in the area of one Regional Board. To work out a really efficient hospital system modifications and changes in the use of existing institutions would be necessary. So far as practicable the objects for which an institution was founded would be followed, instead of changing its purpose merely by whim. The amendment gave no freedom of movement to the Regional Boards or to the Ministry in this matter, and would make impossible the working out of a hospital scheme. The Government must be free to organize and adapt on the complete undertaking that so far as practicable the purposes for which the foundation was made originally should be observed. The proposed amendment was rejected by 29 to 11.

Mr. REID then moved to omit the whole of subsection 5, which deals with the regulations permissible under the clause for interests in premises between the Minister and personnel. He remarked that the subsection started with the words "regulations may provide," but the Committee did not know the lines on which these would be made. The Committee was now discussing premises used partly for hospital purposes and partly for some other purpose.

Mr. KEY said there might, for example, be a hospital institution where arrangements had been made for general hospital treatment but which was connected with teaching hospitals and used for that purpose. It might be necessary to make an apportionment to the governors for carrying out their functions as a teaching hospital, while another part of the institution was used as a part of the general hospital system under the management and control of the Regional Board. All the regulations would be placed before Parliament. Mr. REID said the subsection could not apply to the example given by Mr. KEY. The provision applied only to premises where part was to be taken by the Minister and part was to remain under the old owner.

Mr. KEY said that until the Ministry came up against the problem of adaptation in actual experience it could not say what types of apportionment would be involved. There would be the safeguard of arbitration and the presentation of the regulation to Parliament. The amendment was negatived.

SUPERANNUATION

In subsection 6 of Clause 6, which provides that this section shall not apply to rights and liabilities arising out of contracts for rendering personal services, Mr. KEY moved to omit the rest of the subsection and to substitute:

"Or to rights and liability arising out of any enactment, scheme, or contract providing for the payment of superannuation benefits,

except superannuation benefits payable in respect of officers employed for the purposes of a voluntary hospital who had ceased to be so employed before the appointed day, but this subsection shall be without prejudice to the provisions of Part VI of this Act relating to the transfer and compensation of officers and the superannuation of officers."

The purpose of the amendment was to exclude from the transfers of rights and liabilities the rights and liabilities relating to superannuation in order that they might be considered when the Committee dealt with Clauses 63 and 72. One important exception was where a voluntary hospital had a liability for payment of superannuation to somebody who had actually retired. Liability for that was transferred to the Minister.

Mr. MESSER stated that local authorities were disturbed at the prospect of having to carry the liability into the new service when, in fact, they were not responsible for the officers transferred. Mr. REID said he had in mind officers of certain voluntary hospitals who had no legal right to a pension but had a pension granted at pleasure. In fact the pensions were always paid and the officers had a moral right to them. The question arose in mental hospitals. He trusted it was the intention of the Government to take over that moral liability. Obviously the governors of the mental hospitals would not have any funds in the future and these people would be left stranded.

Mr. KEY said the arrangements under Clause 6 for superannuation did not relate to the carrying on of superannuation schemes for the employees who would be taken over with the institutions. Mr. Reid had raised an important case, and the feeling of the Ministry was that it should give *ex gratia* payments to those people with the permission of the Treasury. That was the intention. The amendment was agreed to.

INTERIM DIFFICULTIES

On the motion that Clause 6 as amended stand part of the Bill, Cmdr. Maitland said it was the duty to some extent of people who controlled hospitals to turn endowments into buildings. He asked the Minister if he would help voluntary hospitals which were now in difficulty about their position in the interim period. Many hospitals had saved during the war to be in a position to build, for example, new maternity blocks. Mr. MESSER said that a month ago his own authority passed a development plan involving £20,000,000. The Minister would not let it spend that sum because it could not give building labour, but the authority had the money and the sites, and the scheme was planned. No time should be lost in informing those hospitals which were to be outside the scheme. Turning to the regulations proposed in Clause 6, Mr. Messer said a recent conference called by the L.C.C., the Association of Municipal Corporations, and the County Councils' Association regarded with disquiet the fact that the Minister was not compelled as the clause stood to provide regulations, and that local authorities or voluntary hospitals would not be able, by right, to choose arbitration.

Sir H. MORRIS-JONES asked how much time the hospitals had before the appointed day and what powers they would have in the interim period so that they could proceed with some of their schemes. Dr. MORGAN, Mr. PIRATIN, and Mr. Linstead asked the Minister to make a pronouncement on special hospitals, such as the Royal Masonic Hospital and the Manor House Hospital. Ministry of Pensions hospitals, and the Swiss, French, and German hospitals in London were cited. Mr. COLLINS said much of the discussion and many of the amendments had not been remotely concerned with the welfare of the people who entered the hospital. His friends desired some assurance on behalf of the patients of prompt entry, swift and accurate diagnosis, skilled medical treatment, careful nursing, and suitable food. Mr. HENRY STRAUSS asked for a specific reference to the registered mental hospitals, some of which were financially independent and were anxious to continue without interference and to make developments; but Dr. TAYLOR hoped the Minister would not give such an assurance.

MINISTER'S REASSURANCE

Mr. BEVAN said there need be no apprehension on the part of hospitals concerning their power to extend, because the limit was lack of labour and materials. But if they had ambitious building projects they would not be able to carry them out. Emergency schemes must be put in hand, and approval had been given for a number of extensions and adaptations. If a hospital had a project which it thought to be one of high urgency it should make an application, and this would be considered. It would be impossible, ahead of the hospital plan, for any regional area to approve great building projects, even if the country had the labour and materials, because the Ministry did not know what would be the relation between one hospital and another until the plan had been made. As soon as the

Bill was passed the Ministry would establish the Regional Boards in order that plans might be made as soon as possible. As they were being made the hospitals would learn what their position was to be. Therefore they would have an idea as the schemes were being formulated, quite a substantial time before 1948. The Bill gave the Minister power to bring parts of the scheme into operation at different appointed days so that all the scheme would not be suspended until one day in 1948.

There was no doubt that any scheme in which the State accepted responsibility for free hospital service would damage and undermine the incomes of voluntary hospitals. But those responsible for voluntary hospitals were keen about their job, and he could rely upon them to keep their hospitals up to the highest pitch of efficiency. In the meantime voluntary hospitals should be maintained by those who had been accustomed to do so, and he hoped that those who could would help the hospitals by donations, and that those who made weekly contributions would continue to do so until the insurance scheme was in operation. Voluntary hospitals might have to eat into their capital resources or incur overdrafts, and these overdrafts would have to be transferred with the hospitals. His statement did not indicate a wish that the hospitals should begin to pile up overdrafts. If they did so they would get into difficulties, not from the point of view of surcharge but because the overdraft would be deducted from the assets when considering how much of the endowment funds were to be made available in the future. So far as possible the Ministry would try to push the endowments down into the management committees where they would fertilize the whole service. Therefore, the vigilance of the voluntary hospitals would assist in building up the funds of which they would have possession later.

He could not say what special hospitals would be left outside, because the Regional Boards must be able to look at all the hospitals available to see what they would need for an efficient hospital service. Furthermore, many of the special hospitals, like sectarian hospitals and hospitals giving special forms of recognized therapy, might want to come into the scheme, because if left out of it they might be ruined. All patients who now went into those hospitals and paid for treatment would be entitled to free hospital treatment. If these special hospitals were brought into the scheme it must be regarded as a principle that their special sectarian and individual character must be preserved. It must be the obligation of the Regional Boards to see that their management committees were of a character which maintained the continuity of the characteristics of those institutions. He gave that absolute guarantee.

He would not say that he intended to lay hands on the Admiralty hospitals or the hospitals of the Ministry of Pensions. These were Crown hospitals. Later, when the scheme was in full operation, he might see how the other Departmental hospitals could be dovetailed into the general health service. He made no definite promise. The Government hoped to serve the plastic surgery groups, which had done magnificent work during the war.

Clause 6 as amended was ordered to stand part of the Bill.

ENDOWMENTS OF VOLUNTARY HOSPITALS

On Clause 7 Mr. REID moved to leave out the words which restricted to hospitals designated by the Minister as teaching hospitals the provision that all the endowments shall be transferred to and vest in the board of governors. He welcomed the stress laid by Mr. Bevan on the importance of having a responsible management committee in charge of a particular hospital group. The Minister should allow the management committee of that group to keep the funds which were now vested in the particular hospitals concerned. In his amendment he was trying to bring the other hospitals into line with the teaching hospitals.

Mr. BEVAN said Conservative members forgot that what the Committee was anxious to do was to take the provision of hospital services away from the atmosphere of private charity. The Chancellor of the Exchequer would have been entitled to take all this money and use it to finance the scheme, because all this money was provided for general hospital purposes. The finances for general hospital purposes would be found by the State. The money under discussion was pocket money. The Ministry would try by global budgets to give the Regional Boards and the hospital Management Committees freedom of movement within the budget, and by making this money available to them would give them even more elbow room to provide more amenities and spend additional sums.

Mr. STRAUSS said the provision in the clause was without precedent. The Courts of Chancery and Parliament had always been careful to follow so far as possible the wishes of donors and testators. Capt. MARSDEN, noting that money coming from voluntary sources was to be pocket money outside the funds provided by the State, asked whether the income allocated year by year from King Edward's Hospital Fund would be seized

and disbursed by the Minister. To this Mr. BEVAN said "No."

The chairman, Mr. BOWLES, said the amendment did not deal with the purpose for which the funds were to be used.

Col. STODDART-SCOTT pointed to the situation in some industrial cities of the North, like Leeds and Bradford, where there was a teaching hospital in a university city next to another city with a large hospital but a university college. In Sheffield and Hull there were a university hospital and a teaching hospital in one city, and a university college and a large hospital in the other. One would retain its endowment and use it as it wished, while the other would get a share-out as the Minister arranged. He hoped the Minister would consider places with university colleges which in time would become universities and might establish medical faculties. What would be the position after the appointed day if the Minister had not made any additional teaching hospitals and some of the university colleges developed medical faculties? Would he be able to give back their endowments to places like Bradford and Hull?

Mr. BEVAN said the Committee would have to deal with that separately. It would have to be managed somehow. That was not the situation at present in connexion with some hospitals. Some had more money than they needed while others had no money at all. That could not be allowed in a properly organized hospital service. If teaching hospitals were created the Ministry would have to provide for them.

On a division the words which Mr. Reid proposed should be left out were retained by 27 to 13. Further consideration of the Bill was adjourned.

Experimental Health Centres

Mr. SOMERVILLE HASTINGS asked on May 16 whether the Minister of Health proposed to set up health centres so that further experience could be gained before the national health scheme came into operation. Mr. BEVAN said he did not think this would be practicable in the light of present statutory powers. He considered it better to press on with the National Health Service Bill and then to gain experience under it as quickly as possible.

Penicillin and the Public

Mr. BEVAN told Dr. Barnett Stross on May 16 that he had not completed his arrangements for the distribution of penicillin. The arrangements would provide that, for the present, penicillin would be available to the public only on the prescription of a qualified practitioner. That should be a safeguard against the danger apprehended by Dr. Stross that by taking small doses of penicillin indiscriminately the public might jeopardize efficient treatment for serious disease.

Dr. STROSS asked Mr. Bevan to take steps to advise the public that penicillin did not cure the common cold, or tuberculosis, or many other constitutional ailments.

Streptomycin

On May 16 Mr. PERCY WELLS inquired to what extent streptomycin was being produced in this country; whether it had been used in the treatment of tuberculosis; and with what results. Mr. BEVAN said a number of firms were carrying on research and development in connexion with this product, but the quantity resulting from these activities, which were on a laboratory scale, was as yet very small. It had therefore not been possible to use streptomycin in the treatment of tuberculosis.

Colonial Medical Service

Mr. GEORGE HALL told Mr. Dodds-Parker on May 15 that there were 128 vacancies in the Colonial Medical Service. The vacancies were being advertised. Appointments were over-taking retirements at the rate of about 15 a month. Mr. Hall added that he was not satisfied that the conditions offered in a number of Colonies were sufficient to attract highly competent specialists, either for short or long terms. He had recently made proposals to a number of Colonial Governments designed to remedy this defect. Some of these Governments had agreed to the proposals; others still had them under consideration.

Notes in Brief

On Jan. 1, 1946, there were 2,693 patients in mental homes and institutions managed for private profit under the Lunacy and Mental Treatment Acts. The number who left or were discharged as recovered or relieved during 1945 amounted to 66% of the number admitted.

Mr. Bevan is considering rules submitted by the General Nursing Council to establish a register of nurses who are trained in the nursing of tuberculous persons.

In England and Wales, at March 31, 1946 (the latest date for which figures are available) the number of persons who had been on waiting lists for institutional treatment for tuberculosis longer than 10 days was about 6,200.

The Services

The following have been mentioned in dispatches in recognition of gallant and distinguished services in the Mediterranean Theatre

Colt (Temp) G Anderson OBE, G T Garraway and H J R Thorne DSO, Lieut-Colt (Temp) F A Bevan TD, H Banbridge TD, S M, Comes A L D'Abruzzo OBE, J Fleming G M, Friell TD, F D Hari A G Johnson B R M, Johnson J B, King A J C, Lakhmire MBE, W A Mill J D W, Pearce R W, Raven L F W, Salmon MBE, J R St G S and A Watson Lieut-Colt (Acting) J B Bishop, Maj R A Facey TD, G D Falconer and R A P Gray, Maj R (Temp) J L C Beale K, Cameron A A, Dickie J A P, Evans D J, Frier A, Findlay R S, Garden A, Gourevitch MBE, J A Gird, n I C Hyland, D Jefferson, H C Johnston, C D P Jones MBE, F Kane A B, Kettle, I Leveson J, Macartney MBE, S MacKenzie W, MacKenzie A A, MacNair R L, Marks W E, Mashier R G, Miller R, Michay P B L, Muldoun A D, Newsholme J G O'Sullivan W A, Owen E, Pereira F H D, Phillips H P, Player A H M, Richards G I M, Ross M J, Saunders J A W, Shearer S B, Smith O H, Theodor F L, Turner W M, Walsh W J, Walter R H, Watson G A, Wilson and C L Worthington, Majors (Acting) C W A, Faloner B S C, Gaster and R I McAlley, Capt H Abramovich, MC, J H Adams P B, Angus J R, Armstrong C L F, Beaton W H C B, H J H Bennett, O H Bostock, J Brod T O, Candler M A, Chamberlain R C, Connolly J H, Cule R B, Davies, W A J, Donald L, Dorman J F B, Edeson P K D, Edmunds G, Godfrey C L, Grandage J, Halliday J M, Hilditch J R, Horn D R, Hughes F G, Hunter, P E, J E, Jaxon D, Klein M, Knowles R A, Lambourne R, Lush H C, Mansfield C R, McClure R, McIlroy J M, Munden H B M, Murphy, D F, Nicholson D A, O'Sullivan R T, Parkin G H, Parkinson I M, Sayers P S, Seen W R, McL Stevenson J H, Stranger B S, Tulloch J P, Turney C P, Wallace R, Watson D, Weitzman M H, West T K, Whaley P J, White and W W, Willson, Capt (Temp) L H Moore, Lieut H Baker R, Frarckham and W A Reynolds R A M C, Lieut-Col R S, Sahu M C, Lieut-Col (Temp) A N de Quadros, Lieut Col (Acting) S M Mohammad, Capt M A Alvi, G L Banerjee, K Chari M A R, Chowdhuri H, Dubey G, Singh N, G, Govind Raj G S, Nair G S, Grewal S M, Kanur P V, Krishnamurthy S, Mitra and H P B Neku, Capt (Temp) S F D Gola and S C, Guha, Lieut N N Banerjee, J S Bains and M K Bhat, Amb Sub A Mohd, Sub M T Khan, Sub (Acting) A Singh, Jerns D Singh G Singh M, Dadd, and S Mohiuddin I A M C

CASUALTIES IN THE MEDICAL SERVICES

Killed in Burma—W/Capt Michael Dean, R A M C

Killed in action Singapore Feb 1942—Major Seth Kenneth Squires R A M C

Murdered in India—Capt Joyce Margaret Hierons R A M C

Murdered, reportedly missing now reported missing presumed killed—Temp Surg Lieut Geoffrey Sulliffing Cross R N V R

Wounded—Brig R M B MacKenna, A M S, Major K B Thornton, R A M C, W/Cap S J T Merryfield, R A M C

EPIDEMIOLOGICAL NOTES

Discussion of Table

In England and Wales there was a decrease in the incidence of acute pneumonia 165, measles 141, and dysentery 75 while an increase was reported for scarlet fever 77 and whooping-cough 33.

A small rise in scarlet fever occurred in most areas, and no large variations from the totals of the preceding week were recorded. The only notable change in the local trends of whooping-cough was an increase of 79 in Lancashire. Notifications of diphtheria increased by 1, the only marked fluctuations being an increase in Lancashire 21 and a decrease in Warwickshire 21. The decline in measles was contributed by London and Lancashire, where 128 and 114 fewer cases were notified than in the preceding week, the only large increase was in Essex 50.

The returns for dysentery were the lowest for the last seven teen months. The largest returns were Lancashire 32, Middlesex 25, London 16, Kent, 12, Warwickshire 10.

The Rock Ferry district of Birkenhead reports 7 cases of smallpox, 2 fatal. The staff of the Health Department and private practitioners have been working at great pressure to deal with the queues of people wishing to be vaccinated, over 10 000 vaccinations were carried out during the first few days.

In Scotland the incidence of infectious diseases declined. The chief falls were measles 250, scarlet fever 34, whooping-cough 22, dysentery 13, diphtheria 9.

In Ire an increase of 20 in the notifications of measles was the only appreciable change in the trends of infectious diseases. This was due to an outbreak in Dublin, Dun Laoghaire U D, involving 27 persons.

Cholera in India

An outbreak of cholera in the Province of Bihar caused the deaths of 2,167 people during the week ending May 4.

Week Ending May 18

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,112, whooping-cough 2,306, diphtheria 369, measles 2,658, acute pneumonia 461, cerebrospinal fever 49, dysentery 120, paratyphoid 2, typhoid 5, smallpox 5.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 11.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for: (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for: (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1946					(1945 Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)
Cerebrospinal fever Deaths	61	3	21	1	—	53	2	22	2	—

Deaths (U-1 year) Infant mortality rate (per 1,000 live births)	53	35	52	53	1	50	35	70	29	24
Deaths (excluding still births) Annual death rate (per 1,000 persons living)	4,301	676	551	210	13	4,664	662	672	217	140
Live births Annual rate per 1,000 persons living	8,366	1241	105	468	29	5,833	621	809	468	22
Stillbirths Rate per 1,000 total births (including stillborn)	276	38	30	—	—	171	14	34	—	—

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county) and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

Medical News

Mr. John Douglas McLaggan, F.R.C.S., has been appointed Aurist to the King.

Dr. Sterling Bunnell of San Francisco, consultant for hand injuries to the U.S. Secretary for War, is visiting this country, and on Wednesday, June 12, at 3 p.m., he will lecture in the anatomical theatre, Guy's Hospital Medical School, on reconstructive surgery of the hand.

The annual assembly of the Faculty of Homoeopathy will be held at the London Homoeopathic Hospital on Wednesday, June 5, at 2.30 p.m., when Dr. F. H. Bodman will give an address on "Teaching and Learning Homoeopathy," followed by Dr. F. R. Neubert, who will speak on "Homo-Apathy—The Orthodox Practitioner Looks at Homoeopathy."

The second quarterly meeting of the Continental Franco-Anglo-American Medical Society will be held at 11, Chandos Street, W., on Tuesday, June 11, at 2.30 p.m., when Lord Horder will preside.

The annual general meeting of the Royal Medical Benevolent Fund will be held at 4 o'clock (not 5 as stated last week, p. 821) on Wednesday, June 12, at 11, Chandos Street, Cavendish Square, W.

The annual general meeting of the British Association of Physical Medicine was held at the Royal College of Surgeons of England, Lincoln's Inn Fields, on May 15, when the report of the Council was presented to the members by the president, Lord Horder. A meeting to consider the treatment and rehabilitation of spinal cord injuries will take place at Stoke Mandeville Emergency Hospital on Wednesday, June 12, at 11.30 a.m. It will begin with a paper on demonstrations by Dr. L. Guttman, and in the afternoon Dr. Francis Bach and the staff of the physiotherapy and occupational therapy departments, together with the surgeon-instructor, will demonstrate the treatment of patients.

The Kettle Memorial Lecture will be given by Prof. W. E. Gye in the anatomical theatre of St. Bartholomew's Hospital Medical College, Charterhouse Square, E.C., on Wednesday, June 19, at 5 p.m. His subject is "Recent Advances in Cancer Research." Medical practitioners and medical undergraduates are cordially invited to attend.

The new address of the Institute for the Scientific Treatment of Delinquency is 8, Bourdon Street, Davies Street, London, W.1 (temporary telephone number (for urgent calls only): Mayfair 7072). To facilitate reorganization the directors have decided to close the clinic to new cases until Monday, June 24. Treatment of current cases will be continued. The lending library also will be closed, for removal, stocktaking, and reorganization, until July 1.

A delegation of seven scientists from Holland has arrived in this country, under the auspices of the British Council, to visit research and other scientific or medical institutions and make contacts with representative British scientists. After a stay in the London area they will visit the Provinces. One or more of the party will travel Oxford, Cambridge, Leeds, Glasgow, Manchester, Edinburgh, Aberdeen, Sheffield, Bristol, and Birmingham.

Prof. P. Lacroix, the Belgian orthopaedic surgeon, is visiting this country under the auspices of the British Council to attend the Conference of Orthopaedic Surgeons at Newcastle and visit Edinburgh, Manchester, and London to see medical institutions and meet British doctors.

The Swiss Academy of Medical Sciences is organizing a British-Swiss Medical Conference to be held in Basle from Sept. 16 to 21. An organizing committee has been set up in England, under the chairmanship of the President of the Royal Society of Medicine, and the following institutions are represented on that committee: Royal College of Physicians, Royal College of Surgeons, Royal College of Obstetricians and Gynaecologists, Medical Research Council, Physiological Society, Pathological Society of Great Britain and Ireland, and the British Council. Medical men from this country are cordially invited to participate, and they may take their families with them if they wish. Special arrangements will be made for the entertainment of non-medical visitors attending the conference. A detailed programme of speakers and subjects will be circulated at a later date. Thomas Cook and Son, of Berkeley Street, W.1, are handling the bookings, and reservations should be made with them before July 1.

To mark the L.N.E.R. Company's appreciation of the splendid work which doctors from Durham City and the neighbourhood performed at the railway disaster at Brownay Colliery last January, Mr. C. M. Jenkin Jones, divisional general manager, has sent a cheque for 50 guineas to the treasurer of the Royal Medical Benevolent Fund, adding that some of the doctors who helped were travellers on the train. Another cheque for 50 guineas has been sent to the Durham County Hospital in recognition of similar services by the medical and nursing staffs there.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Allopathy Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.) TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate Westcent, London*.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Reaction after Radium Treatment

Q.—A patient had radium treatment for skin carcinoma of the ear (6,500 r in six days) in October, 1945. He has since complained of general debility and failure of mental powers. Are these the result of the radium treatment?

A.—The dose of radiation for the destruction of a skin carcinoma is necessarily large, and the local reaction before healing takes place is severe, but the action and reaction are localized. General debility and failure of mental powers could not be caused by the local radium treatment of the ear.

Penicillin Spray for Bronchiectasis

Q.—Would the penicillin spray method of treatment help an old-standing case of unilateral lobar bronchiectasis?

A.—Most large hospitals in England are now using, in the treatment of cases of infection of the bronchi, including bronchiectasis, inhalation of a mist containing penicillin. It is difficult to obtain adequate concentration of penicillin in the atmosphere of a room, and it is usually preferable to atomize a penicillin solution of 20,000 units per ml. with oxygen, and for the patient to breathe in the mist through a plastic face-piece of the shape used in inhalation anaesthesia. With the best type of inhaler it is possible to obtain a penicillin concentration of 5 units per ml. in the patient's sputum.

This method of treatment will be increasingly used in the future, and should always be controlled by assay of the penicillin in the sputum. It is impossible to obtain adequate concentration by using a hand- or foot-bellows and ordinary air; also, the droplets of the mist must be sufficiently small to be non-irritant to the larynx. Using a suitable inhaler and adequate oxygen pressure, 2 ml. of penicillin solution can be vaporized in fifteen minutes, and, if this quantity is breathed every two hours, an adequate concentration of penicillin is obtainable in bronchiectatic cavities. It may be that the predominant organism in the cavities is not penicillin-sensitive, but, in general, even long-standing cases are much improved.

Posture in Sleep

Q.—What is the ideal posture for slumber? Can faulty posture, particularly in the obese, be responsible for straining the sacro-iliac or other ligaments, so causing backaches or similar complaints?

A.—There is no "ideal" posture for slumber. An easy relaxed position for the body in the horizontal state is all that is required to satisfy the normal basal physiological requirements for the short number of hours needed. The story is very different in the care of the invalid confined to bed for long periods. Here posture is extremely important, for far more than basal physiological requirements have to be met. It is in this field that the most flagrant departures from the principles of "physiological rest" are occasionally found. It is faulty posture in the obese or, in fact, in any other person in bed for a long period that is responsible for much of the backache which is prone to follow. Sitting up with the knees straight, the feet unprotected, with the lumbar region unsupported is common and is associated with abdominal visceral compression and poor respiratory excursion. This is a very

large subject, but one feels that it is in this field that great improvement could be provided in the medical and nursing care of the chronic sick.

Pyloric Stenosis and Haematemesis

Q.—Is there any association between pyloric stenosis and haematemesis in infants, and is there any factor in the stool of an infant under 6 months which, in the absence of demonstrable causes of bleeding, would give a positive benzidine reaction to tests for occult blood?

A.—In congenital pyloric stenosis a certain degree of gastritis is common. With this the vomit may be dirty, brown, and even blood-stained. There is no known association between pyloric stenosis in infants and any other cause of bleeding. A positive test for occult blood in the stools of an infant receiving only milk, orange juice, and cod-liver oil must presumably indicate bleeding somewhere in the alimentary tract (or swallowed blood from a cracked nipple).

Mental Ulcer

Q.—A 3-year-old boy was circumcised last December. A few weeks ago he developed a mental ulcer. What is the treatment?

A.—Phimosis is often associated with a small meatus, requiring a meatotomy, and this is almost certainly the cause of the mental ulcer. A meatotomy should therefore be carried out, with subsequent dilatation of the meatus with a bougie to prevent it contracting again. The dilatation may have to be carried out more than once, and an anaesthetic will probably have to be given, otherwise the mental ulcer is likely to recur continually, even although it temporarily heals. The treatment of the tight meatus so often associated with phimosis is, indeed, more important than the circumcision itself.

Asparagus, Urine, and Skunks

Q.—What makes urine smell so unpleasantly after eating asparagus?

A.—It is not known for certain what is the substance which, after eating asparagus, gives the smell to the urine, but it is probably methyl mercaptan. M. Nencki (*Jahresbericht über die Fortschritte der Tierchemie*, 1891, p. 193) distilled the urine of four men—who had consumed between them 12 kg. of asparagus—with oxalic acid; the gas evolved was passed into mercuric cyanide solution; the precipitate so obtained was distilled with dilute HCl into lead acetate solution, and a pale yellow crystalline precipitate of the lead salt $Pb(SCH_3)_2$ was obtained. It is said that the smell of the skunk is due to butyl mercaptan.

Mercurial Diuretics

Q.—In a case of congestive heart failure can injections of a mercurial diuretic be continued over a long period if necessary? If not, what are the indications for withdrawal, and is any other form of therapy possible?

A.—Intravenous injections of the mercurial diuretics may be given over a period of many months, and even two or three years, without producing undesirable side-effects in the kidneys or elsewhere. In general, it is best not to repeat the injections more frequently than every five days. Restriction of the fluid intake, avoidance of salt in the diet, and the administration of ammonium chloride 20 gr. (1.3 g.) in capsules thrice daily for forty-eight hours before each injection may enhance the effect and allow less frequent dosage. Patients may at any time develop idiosyncrasy to the drug; the lesser grades of sensitivity are manifested by skin disorders, such as urticaria or erythema; more severe reactions include purpura and exfoliative dermatitis. A positive patch test will prove the relationship of the drug to the eruption and indicate withdrawal. Allergy, as indicated by cutaneous lesions, often passes off after withdrawal for a week or two, and the injections can then be resumed in smaller dosage, or at longer intervals, without further sensitivity developing.

Accumulation of mercury in the body may occur if the dosage is too great or too frequent; it is to be suspected if poor diuresis is obtained in spite of the existence of oedema. Digestive disturbances, such as vomiting or diarrhoea, may

arise, and occasionally haematuria or stomatitis. These disorders will generally preclude further use of mercurial diuretics. If mercurials have to be withdrawn, a trial may be made of furosemide 10 gr. (0.65 g.) thrice daily or of theophylline ethylenediamine 7½ gr. (0.5 g.) by intramuscular injection daily for three days. Failing these measures, mechanical drainage by Southey's tubes may be undertaken.

Colloidal Vanadate Reaction in Cancer

Q.—What is the colloidal vanadate reaction, and what is its value in assessing the progress of malignant disease?

A.—The colloidal vanadate reaction was introduced by Bendien in 1931 as a diagnostic test for cancer, and subsequently modified by Cronin Lowe (*Journal*, 1933, 1, 407). The reaction depends upon the effect of vanadate solutions on the blood serum, the results being interpreted by estimation of the precipitations obtained. The chief factor in producing differences in precipitation is probably the globulin content, and while the serum globulin tends to be high in cancer, the same applies in many other diseases, so that the test cannot be regarded as specific. For this and other reasons—for example, that the test is a delicate and variable one, and that special care is required in the collection of the blood specimen, in the preparation of the vanadate reagents, and in the technique itself—the value of the reaction in assessing the progress of malignant disease is a somewhat controversial matter. An excellent review of the changes in the serum proteins in malignant disease is given by Boyland (*Cancer Review*, 1932, 7, 433).

Negative Sputum in Tuberculosis

Q.—A young man aged 38 has the clinical signs and symptoms of pulmonary tuberculosis. A radiograph shows infiltration of both lungs, with a cavity in the right side. Examination of the sputum by the ordinary staining method is persistently negative. No culture has ever been made owing to technical difficulties. Can I exclude pulmonary tuberculosis without attempting a culture of the T.B.? In other words, is a culture absolutely necessary for a final diagnosis? Is there any possibility of a case of pulmonary tuberculosis having a persistently negative sputum by the ordinary direct smear examinations?

A.—A negative sputum smear examination does not exclude pulmonary tuberculosis, in fact, it is not unusual to find patients with extensive disease, particularly chronic disease, and a persistently negative sputum. If a constant search is made the bacilli will usually be found after a time, and, of course, cultural methods are a great help. In this particular instance probably the safest course would be to regard the patient as suffering from pulmonary tuberculosis and to continue to make daily examinations of the sputum. These will probably reveal the bacilli before long.

Diarrhoea

Q.—The article on "What is Gastric Flu?" (March 23, p. 439) implies that there is a clinical entity with diarrhoea as a dominant symptom that may be primarily an infection of the central nervous system. (1) Will you please give further information about this? (2) In the summer of 1943 I saw two cases with sleeplessness, nausea, diarrhoea, and "feeling frightened." It seemed possible that the symptoms were due to an infective agent, or a toxin formed by one, that acted on parts of the nervous system involved in fear reactions, and that the diarrhoea was brought about through those physiological mechanisms that are operative when diarrhoea is caused by fear. Are there any observations that would confirm or refute this view?

A.—(1) The musculature and secretory activity of the bowel are under the control of the sympathetic nervous system, which, if irritated or otherwise affected by some noxious agent, may cause abnormal bowel movements with resultant diarrhoea. Thus, in poliomyelitis, the virus of which is neurotropic, intestinal disturbance may occur early in the infection and these symptoms may be related to the invasion of the sympathetic ganglia by the virus. In the diarrhoeas of early infancy evidence of inflammatory reaction in the bowel is usually lacking, and the suggestion has therefore been made that the symptoms may be due to an irritative effect by virus or toxin on the sympathetic nervous system. So it may be with the epidemic

virus diarrhoea of adults which has lately become prevalent in this country.

(2) The diarrhoea associated with excitement or fear is usually attributed to the over-secretion of adrenaline, which stimulates the sympathetic nervous system in its action. It does not act through the sympathetic nervous system but directly on involuntary muscle, and in this way may cause an intestinal upset. The cases described possibly belong to this category with a "functional" rather than an organic origin for the syndrome.

Erythema Multiforme

Q.—What is the aetiology of erythema multiforme? What is the treatment?

A.—Erythema multiforme claims numerous and different aetiological factors, such as focal infection, or an association with inflammatory ringworm, or as representing part of the symptom complex of poradenitis venerea. The occasional pain and joint swelling have suggested a rheumatic or streptococcal origin. Most attacks run their course in three to four weeks. Routine treatment includes rest in bed and a sodium salicylate mixture. In the recurrent form, which is uncommon, a variety of dermatitis herpetiformis may be suspected. A careful search for an underlying cause, such as chronic focal sepsis, or gastrointestinal or even renal disease, may be required.

Gastric Disorders in Aircraft Production

Q.—An employee complains of his stomach being upset by the spray used on aeroplanes for preserving them. He says it contains resin and lanolin, and that masks are supplied for use when spraying, but it is impossible to wear them if the nose is stuffy, as when he has a cold. Is this psychological, or is there some harmful effect on the digestive organs from this spray?

A.—It seems most unlikely that a spray containing resin and lanolin would be used for preserving aircraft. The material usually sprayed on aircraft is "dope," which is a type of paint. This contains aromatic hydrocarbons, including toluene, xylene, and benzene up to 15%, and amyl acetate, among other substances. A rubber solution containing naphthalene is sometimes sprayed on metal parts to prevent scratching. None of these substances is known to have a harmful effect on the digestive organs, and it is, therefore, probable that the symptoms are psychological. Many people have a feeling of nausea on entering a freshly painted room. The wearing of a mask can never be said to be pleasant, and it is always difficult to persuade workpeople to wear them. If there is nasal obstruction, further obstruction in the form of a mask is sure to be uncomfortable.

INCOME TAX

Car Expenses

N. W.'s car has been written down by depreciation allowances to £52. What will be the position if he sells it in 1946-7 for £200 and buys a smaller car for, say, £1,200?

His tax liability for 1946-7 will be unaffected. As regards 1947-8 (a) he cannot claim "replacement cost" because he has had the depreciation allowance on his present car; (b) he will be liable on a "balancing charge" in the amount of £200-£52=£148; and (c) he can claim the "initial allowance" of 20% of £1,200=£240, plus the "depreciation allowance" of 25% of £1,200=£300.

Cash in Lieu of Residence

B. C. as a demobilized M.O. received "£350 plus £100 in lieu of residential emoluments if not in residence." Is the £100 liable to tax, and if so can any deduction be made from that amount for the cost of private residence?

The recipient of emoluments in kind is fortunate in that such an indirect financial benefit is not taxable. Where cash is received in lieu the recipient is in the same position as the great majority of salary earners—i.e., tax is payable on the full amount of the emoluments and the cost of personal expenses of living cannot be deducted.

Ship Surgeon: Residence

"LEX," who has previously been resident abroad and has no residence or permanent abode in this country, holds an appointment as a ship surgeon on a ship registered and owned here. Does this render him liable to income tax on War Loan interest or income from abroad?

Apparently "Lex" cannot claim to be residing abroad, and is therefore liable on the income mentioned above.

LETTERS, NOTES, ETC.

Inhalations for Asthma

Dr. CLEMENT FRANCIS (London, W.1) writes: I am very glad to see the timely warning in the *Journal* against the practice of inhaling adrenaline solutions of a strength of 1 in 100 in asthma (*Journal*, April 27, p. 671). I was recently asked to see a young woman who for the relief of asthma had been inhaling adrenaline vapour of the above strength at frequent intervals for several weeks. She was collapsed, with an extremely rapid and irregular pulse; but showed rapid improvement on removal of the inhaler and admission to hospital under Dr. Saxby Willis, who has kindly informed me that the administration of sedatives quickly relieved her symptoms. I can confirm the statement that the use of an inhalant solution containing 1% cocaine does not lead to an addiction to the drug, and I have never known a patient who was not at the moment suffering from an asthmatic attack to show any desire to use such a preparation.

Inhalations of vasoconstrictors and antispasmodics usually give rapid relief in asthma, and the method is undeniably simple to use; but it must not be forgotten that local application of the vapour of solutions of adrenaline, cocaine, atropine, papaverine, and pituitary extracts causes paralysis of the cilia of the bronchial mucosa. This objection does not apply to 1% ephedrine, which according to Van Aleya is the only vasoconstrictor in common use which does not cause ciliary paralysis. If the asthma inhalation is used only occasionally—e.g., once or twice a week for a short period—no permanent damage to the cilia results; but when inhalations are used several times a day for successive months the bronchial cilia are destroyed. Moreover, the repeated inhalation of powerful vasoconstrictors results in a reactionary vasodilatation, so that the bronchial mucous membrane becomes chronically thickened and the asthmatic patient finds that he or she is becoming increasingly short of breath on exertion, that coughing is more troublesome, and expectoration more difficult. The above symptoms are unlikely to be produced when the patient relies on an oral remedy such as iodide of caffeine, or, if a more powerful means is necessary to combat an attack, a subcutaneous injection of a few minims of a solution of adrenaline 1 in 1,000.

Village Longevity

Dr. A. C. L'ESTRANGE (Clows Top, near Kidderminster) writes: Dr. C. E. S. Harris's longevity record (May 4, p. 709) is indeed very good, but I think the Teme Valley, Worcs, takes a little beating in "long-livers." My last ten death certificates read: 104, 91, 80, 74, 74, 84, 93, 53, 89, 81; total, 823 years, giving an average of 82.3. It was most unfortunate that the 53-year-old broke the "run," as my 11th certificate was for 83 years.

Nocturnal Erections

Dr. H. S. GASKELL (Stowmarket) writes: I note under "Any Questions?" (May 4, p. 707) a reference to nocturnal erections in elderly men, and that the answer was that when nothing is found to account for it "very little help can be given." Ten years ago a widower aged 70 was much troubled with this symptom. I gave him 6 weekly intramuscular injections of testosterone, 50 mg. each time. The trouble immediately disappeared, and the patient, who is still hale and hearty at 80, and carrying on his business, has repeatedly told me since that he has never had a recurrence.

Major E. S. A. ASHE, R.A.M.C., writes: With reference to the question and answer on nocturnal erections (May 4, p. 707), an article by H. Gaudin in the *New Zealand Medical Journal* of 1943 suggests stilboestrol in doses of 0.5 to 1.0 mg. for the relief of the above. In one of his cases complete relief was obtained after 3 doses, and it might be worthy of trial, on the assumption that it is a symptom of the male climacteric, etc.

Menstrual Migraine

Dr. E. D. GRAY (Manchester) writes: In the answer under the above heading (Feb. 2, p. 190) it was implied that "calcification of the roof of the pituitary fossa" might be a factor in the selection of the appropriate treatment of menstrual migraine. Surely it is well known that this appearance of a calcified roof does not represent a real encroachment of the sella turcica. It is caused by ossification of the dural folds connecting the anterior and posterior clinoid processes. Such ossifications are frequently seen in lateral radiographs of the skull in both males and females. No evidence has been adduced to suggest that this bridging of the sella could have any effect on the pituitary gland; indeed, if one considers the position of the anterior and posterior clinoid processes relative to the middle line, it must be obvious that tubular bands of ossification between these points could not possibly influence pituitary function. The appearance of an enclosed sella should be regarded as an incidental point and no clinical significance should be attached to it.

LONDON SATURDAY JUNE 8 1946

THE SOURCE AND TRANSMISSION OF NASOPHARYNGEAL INFECTIONS DUE TO CERTAIN BACTERIA AND VIRUSES

BY

RONALD HARE, M.D. AND DOROTHY M. MACKENZIE, B.A.

(From the Connaught Medical Research Laboratories,
University of Toronto)

In view of the interest now being taken in the possibilities of ultra-violet light and aerosols for the prevention of nasopharyngeal infections, this paper discusses the probable methods by which the bacterial and virus infections of the nasopharynx are disseminated. For various reasons only scarlet fever, tonsillitis, pneumonia, diphtheria, and meningitis will be considered among those due to bacteria; and of those caused by viruses, only influenza, measles, and the common cold (it being freely admitted that direct proof of the virus origin of the last is still wanting).

Spread of Bacterial Infections

There is abundant evidence that preceding an outbreak of bacterial infection of the nasopharynx a slow increase occurs in the carrier rate, and not until this has reached a certain

increases when he carries on some form of nasopharyngeal activity. Even so, the great majority of the expelled organisms come from the mouth, few or none coming from the nose. The mechanism of expulsion itself has been recently reviewed in detail by Duguid (1945), while Hare (1940) described experiments which indicated the path followed by the organisms after leaving the mouth. These experiments have been repeated and extended. In brief, the method employed is as follows.

A subject sits upright in a quiet room and counts for five minutes, coughs six times, sneezes once, or blows for two minutes directly forwards with his mouth in the centre of a quarter circle of culture plates. In most experiments the circle has been twelve inches (30 cm.) in radius (Figs 1 and 2). The plates are situated on the radii at 90°, 67.5°, 45°, 22.5°, and 0° from the vertical, the first-named being directly in front of the mouth and the last directly

FIG. 1

FIG. 2

level do clinical cases appear. In the course of this, it may be assumed that, in general, the infecting bacteria reach the recipient in the air he breathes and gain access to the atmosphere from the nose or mouth of the case or carrier. The presence of the specific organisms in the air may arise in two ways: (1) by expulsion of the organisms from the nose or mouth when the case or carrier indulges in such activities as speaking, coughing, sneezing, blowing, or spitting; and (2) by contamination of the hands, handkerchief, pillow, bedding, towels, or any other object which has access to the secretions of the mouth or nose and from which they can be released after the secretions have dried. These two mechanisms must be discussed separately.

Expulsion from Nose or Mouth

In experiments, which need not be quoted in detail, it has been determined that few organisms reach the atmosphere when the subject breathes quietly, but that the number rapidly

under it, all of them twelve inches away. After incubation, the number of colonies on the plates are counted. The collected results are given in Table I.

TABLE I.—Average Number of Colonies per Person on Culture Plates Exposed at Different Positions in Relation to the Mouth

Position of Culture Plate	Talking		Coughing		Blowing		Sneezing	
	Average	% of Total	Average	% of Total	Average	% of Total	Average	% of Total
0°	23.1	30.0	6.7	4.9	1.3	2.6	355.8	7.5
22.5°	39.1	41.8	8.9	6.5	1.6	3.2	1,636.0	34.4
45°	16.2	17.3	60.1	43.9	8.0	16.0	2,425.6	51.1
67.5°	8.4	9.0	52.9	38.7	27.0	54.2	262.8	5.5
90°	1.8	1.9	8.2	6.0	12.0	24.0	71.3	1.5
Total	93.6	100.0	136.8	100.0	49.9	100.0	4,751.5	100.0
Number of subjects	39		20		3		9	

It is not suggested that all the expelled organisms appear as colonies on the plates, but the method does give an indication of the route they take after leaving the mouth. For this reason it would appear that the great majority of the organisms are in droplets of fairly large size whose trajectory depends on the resultant of the force of gravity acting perpendicularly to their initial motion and on the amount of force used in expelling them. Naturally the trajectory is somewhat flatter when violent methods of expulsion are used than when talking, the result being that the majority of the organisms were on the plate at 67.5° from the vertical when blowing, on those at 67.5° and 45° when coughing, on those at 45° and 22.5° when sneezing, and on the plates at 22.5° and 0° (directly under the mouth) when talking.

In the above experiments the head was in the natural position, but if it be inclined forwards so that the mouth is pointing directly downwards over the plate at 0°, gravity assists the force of expulsion and quite large numbers of organisms can be isolated on that plate. If, on the other hand, the mouth faces upwards, very few organisms travel any distance at all, most of them apparently falling back on to the face.

Thus it is obvious that gravity exerts a very powerful influence on the droplets, the great majority of those which contain organisms falling downwards shortly after they leave the mouth. The ultimate fate of the organisms therefore depends on the position and the surroundings of the donor as well as the force exerted in expelling them. While sitting at a desk or table, lying in bed or in similar positions, a very high proportion of the total output will impinge on some surface below the mouth, and only by the more violent methods will it be possible to avoid this and obtain droplets with a flat enough trajectory to float free before becoming "neutralized" by falling on some such surface. Some idea of the numbers which may be expected to do this may be gained from the number of colonies obtained on the plate at 90°, directly in front of the mouth. As will be seen from Table I, the largest number was obtained with the subject sneezing—71.3 colonies (though, had not the subjects unanimously jerked their heads downwards, it might have been larger)—and was smallest when talking, only 18 colonies being obtained. When these figures are compared with the 4,061.6 colonies obtained on the plates at 22.5° and 45° when sneezing, and the 67.2 obtained on the plates at 0° and 22.5° when talking, it is obvious that under most circumstances the vast majority of the droplets containing organisms will be "neutralized" by falling on to some object below the mouth.

When the subject is standing upright, however, with from four to six feet (120–180 cm.) of air below the level of his mouth, some of the droplets will be neutralized by falling on to his clothes, some by falling direct to the ground; but many will rapidly lose water by evaporation, leaving their salts, non-volatile substances, and bacteria as droplet nuclei (Wells, 1934). These are so small that the force of gravity is unable to overcome the resistance of the air, and in consequence they float free. The number of droplet nuclei produced, as well as the number which contain organisms, will naturally depend on the particular activity of the subject. Some idea of the extent of bacterial pollution of the atmosphere which can occur in this way may be obtained from the following type of experiment.

The nose and mouth of a subject were projected into a large box, 51 in. (130 cm.) high, 32 in. (80 cm.) wide, and 21½ in. (55 cm.) deep, the mouth being placed 24 in. (60 cm.) from the floor. The walls and floor were covered with muslin soaked in liquid paraffin to neutralize the larger droplets falling on them. Five blood-agar plates were placed on the floor and exposed for one hour before the activities enumerated below. They were then removed, the subjects talked, coughed, or sneezed, and after an interval of five minutes a second series was inserted through a hole in the wall. They were left for one hour in order to collect the lighter particles slowly settling out from the air. Following incubation at 37° C., the difference between the number of colonies on the two series of plates was assumed to represent the number of nasopharyngeal organisms collected as a result of the particular activity of the donor.

It was found that after talking for five minutes nine normal persons produced an average of 13 colonies, after six coughs 28, and after one sneeze 715. Thus it is obvious that sneezing is by far the most prolific activity, air pollution being quite mild after only talking and coughing. Duguid (1945) used much the same technique but sampled the air directly with a slit sampler,

and similarly found that only by sneezing was it possible to obtain any large numbers of the lighter droplets and droplet nuclei containing organisms.

Thus the number of organisms expelled varies according to the violence of the methods used for expelling them; the path they take after leaving the mouth will likewise vary with the particular activity of the donor, but will in general be downwards rather than forwards, and their ultimate fate will depend to a large extent on the position of the mouth in relation to surrounding objects, but will generally involve the deposition of the organisms on some surface below mouth level. Those which do not reach such a surface will float free as infected droplet nuclei. Lastly, it should be pointed out that without sneezing or violent blowing it must be almost impossible for the subject to project any considerable number of organisms into the mouth of another person on the same level and only 12 in (30 cm.) away.

Expulsion of Specific Organisms by Carriers and Cases

Using the same methods, Hare (1940) studied 12 known carriers of group A haemolytic streptococci. As might be expected, under the influence of gravity these organisms tend to fall away along with the nasopharyngeal saprophytes. But of equal importance is the fact that very few of the colonies on the plates contained the specific organisms. This information is summarized in Table II, in which are given the total number of

TABLE II.—Total Colonies and Those Containing Group A Haemolytic Streptococci Isolated on Plates Exposed at all Settings with Head Upright

colonies collected, as well as the number containing haemolytic streptococci isolated at all the sittings in which the heads of the carriers were upright. Seven of the carriers did not expel any haemolytic streptococci during the tests, though three of them expelled some when the head was turned downward. Acutely infected cases were not studied, though several were examined as soon as they were convalescent. But Bloomfield and Felt (1924) encountered considerable difficulty in obtaining expulsion of infected droplets from patients with scarlet fever and tonsillitis during the acute phase of the illness. In a recent paper Duguid (1946) described an investigation of 50 cases of scarlet fever and 37 carriers who coughed six times at blood-agar plates held only 3 in. (7.6 cm.) away from the mouth. About 10% of the total colonies contained haemolytic streptococci, but only 39 out of 87 individuals expelled them.

The expulsion of pneumococci and of meningococci does not seem to have been investigated by a similar technique. Teague (1913), however, held serum-agar plates 3 in. from the mouth of patients with diphtheria who were talking and coughing. Only 48 out of 180 plates contained the specific organisms, only 65% of the patients emitted them during the period of test, and in 30 out of 48 patients only one colony per plate was isolated. Similar results were obtained by Duguid (1946) with patients coughing six times at tellurite plates. The specific organisms comprised only 4% of the total output, and they were isolated from only 10 out of 50 patients. No comparable experiments have been carried out with carriers, but, in view of the statement of Copeman *et al.* (1922) that they have very few diphtheria bacilli in their throats, it would seem that the ability of both case and carrier to emit the specific organisms is no better than that of carriers of haemolytic streptococci.

Thus the available evidence suggests that only a proportion of carriers of streptococci and diphtheria bacilli (and patients

in the acute stages of infection) expel these organisms, and that the organisms which they do expel will, in most circumstances fall and impinge on some surface below the level of the mouth. Those which do not will float free as infected droplet nuclei but in view of the fact that very few droplet nuclei produced as a result of other activities than sneezing contain organisms at all, and the number of specific organisms expelled by a carrier is only a small fraction of the total output, it follows that the production of infected droplet nuclei by carriers of these organisms can hardly be a serious factor in the dissemination of infection.

Much less is known about the expulsion of meningococci and pneumococci but it may be assumed for the present that it proceeds along the same lines.

Contamination of Person and Surroundings

Working with carriers of haemolytic streptococci Hare (1941) showed that the skin of the face and hands, the clothing and the handkerchief may be contaminated by their organisms and that this contamination may persist over long periods of time. The same author, and also Hamburger, Puck, Hamburger and Johnson (1944), showed that the bedding and the dust of the carriers' rooms are contaminated. There is also evidence that the nasal carrier is more capable of polluting his surroundings than the throat carrier, and Hamburger, Green and Hamburger (1945) found that the bedding of such carriers might contain 80 times more streptococci than that of throat carriers. Exactly how the organisms reach the person and the bedding has not been determined. It is probable that some reach it during conversation and coughing but that the majority come from nasal or oral secretions directly. However they arrive, there is no doubt that there may be quite marked contamination.

There is also evidence that the organisms may be released into the atmosphere from these situations. Before this can occur the particular secretion must be dry. Using a wind tunnel Willits and Hare (1941) showed that lint infected with haemolytic streptococci did not infect the air stream so long as it was moist, or even when dry so long as it was undisturbed. But once dry, very slight degrees of agitation sufficed to release considerable numbers of organisms into the air stream. For the same reason, it is possible to show that there may be little or no air contamination in the neighbourhood of the bed of a carrier when all is quiet, but that the number of specific organisms in the air increases very considerably if the bed is made or agitated only slightly (Willits and Hare, 1941, Thomas and van den Ende, 1941, Hamburger, Puck, Hamburger, and Johnson, 1944).

Much less evidence is available in respect of the other bacteria although Stillman (1917) found Types I and II pneumococci in the dust of 48 out of the 183 households in which cases had occurred, but only one Type I in 62 control households. Eagleton (1919) found meningococci in the air of Army huts in which carriers were sleeping. The ability of carriers of diphtheria bacilli to contaminate their surroundings does not appear to have been investigated, although Wright, Shone, and Tucker (1941) found them in the dust of wards in which there were cases.

Mechanism of Transfer from Person to Person

The investigations reported in the preceding section show that, unless extremely violent and impolite methods are employed, it is probably very difficult for a carrier to infect the atmosphere in his vicinity to any great extent directly from his mouth or nose. Furthermore, he is equally unable to infect directly, by any other method short of violent sneezing or blowing, another person whose mouth is only 12 in (30 cm) away and on the same level. On the other hand, his person, the objects which surround him, and particularly his bedding, may be contaminated by his organisms, some having presumably reached them from the droplets which have fallen in the course of conversation, etc., but probably a far larger proportion by direct contact with his nasal and buccal secretions. As the organisms on the surrounding objects can reach free air after drying, Hare (1940) suggested that it was these organisms which are responsible for conveying infection to others.

This hypothesis was put forward to explain the transmission of haemolytic streptococcal infections, but there would seem to

be little doubt that it also applies in other bacterial infections of the nasopharynx. In view of this, it is to be expected that little or no transfer of infection would occur during ordinary contacts of the day, but that an ill-ventilated office or crowded class room, and particularly the dormitory, would be the place where infections of this type are acquired. Epidemiological observations confirm this, for the work of Glover (1918) on the spread of meningitis, of Glover and Griffith (1931) and of Dudley (1926) on the spread of streptococcal infections, of Dudley (1926) on the spread of diphtheria and of Schroder and Cooper (1930) and Strom (1932) on the spread of pneumonia, all point strongly to the importance of the sleeping-place and, to a somewhat less extent, of the class room in the epidemiology of these infections.

This would seem to be due to the fact that during the daytime the number of infectious particles expelled direct into the atmosphere or released from objects available for contamination seldom reaches dangerous proportions, although something approaching it may occur in class rooms or offices with closed windows when the clothing is shaken or handkerchiefs are waved about in the air. But in the dormitory a high proportion of the organisms collected on the bedding during the night are released at once when the room awakens and the occupants get up, and, in common with others, we have found that the bacterial population of the air of Army huts increases ten to twenty times following reveille. It is the sudden release of the concentrated output of the night which makes available enough infected particles to increase the number of carriers or bring about clinical infections.

Spread of Virus Infections

It is generally assumed that epidemics of influenza, measles, and the common cold are due to linear spread over the lines of communication, and that a gradual increase in the carrier rate an apparent prerequisite for the development of an outbreak of bacterial infection, does not occur. However, it has recently been demonstrated that mouse pneumonia virus may remain latent in the tissues of a number of different species of laboratory animals passing from animal to animal without apparent clinical infection. The virus may be mobilized, however, and cause infection, with the production of specific antibodies, by the application of a suitable non-specific stimulus such as the intranasal instillation of sterile suspensions of egg embryo and similar materials (Eaton and Van Herick, 1944, Horsfall and Curnen, 1946). A slightly different but essentially similar mechanism has been invoked by Shope (1944) to account for the spread of swine influenza. It is possible that something similar occurs in influenza, measles, and the common cold, the latent virus corresponding in some degree to the bacteria in the throat of a carrier.

What the essential change may be which causes the virus to awaken and produce clinically apparent infection is open to conjecture, but in view of the fact that colds, particularly in North America, almost invariably appear immediately after the sudden drop in temperature which heralds the autumn, that, although influenza may occur in the summer, recent epidemics of influenza A and B have been winter diseases in both hemispheres, and that measles usually makes its appearance in the autumn, it would seem that weather may play some part in this.

Nevertheless this does not provide a complete explanation; for if latent virus is widely disseminated before an outbreak it is probably in isolated pockets or cells of the population rather than in a high proportion of the population as a whole. What proportion of the world is seeded in this way, and how far apart the pockets are, are matters for conjecture. In the measles outbreak in the Faeroes investigated by Panum (1939), for instance, it is highly improbable that any latent virus was present before the epidemic began. For all the cases were traceable to other cases, and isolated households remained free until contact with cases was established. On the other hand, in a large town the virus may well survive from one epidemic to the next in a few individuals scattered here and there.

Before influenza epidemics, only a few members of the population can very well carry latent virus, for in the pandemic of 1918 isolated islands escaped. In the Samoa group, for instance, the American island of Pago Pago remained free because a strict quarantine was imposed but the islands of

Upolu and Savaii were almost certainly infected by the steamer *Talune*. In the Falkland Islands epidemic of 1935 it was observed that settlements which had been warned by telephone isolated themselves immediately and escaped infection, so that in time "the island could be divided into sharply defined areas where the disease was or was not present" (Cheverton, 1937). In the pandemic of 1889 Parsons (1891) observed that deep-sea fishermen and lighthouse keepers did not become infected so long as they remained isolated. Thus it would appear that if latent virus plays much part in the genesis of epidemics of influenza it is only in very isolated pockets.

In the common cold, on the other hand, it would seem that latent virus must be quite widespread during interepidemic periods, in view of the unanimity with which the populations of whole countries, and even continents, appear to become infected with the advent of cold weather in the autumn.

Thus, if it be allowed that an epidemic starts as a mobilization of the latent virus in isolated pockets of the population, there must in addition be case-to-case transfer of the virus in order to account for the large number of secondary cases which quickly appear. This transfer, moreover, must occur with great rapidity and very easily.

The path by which viruses travel from person to person is quite unknown, but it may for the present be assumed that the same mechanism operates as in the bacterial infections. In consequence, it may be postulated that the recipient inhales virus particles which have reached free air from the patient either by direct expulsion from the nasopharynx or from buccal or nasal secretions which have dried on his person or surrounding objects.

Expulsion of Viruses

Direct study of the expulsion of virus particles is a difficult proceeding, and, so far as we are aware, has not yet been attempted. If, however, as few virus particles are expelled as are streptococci by cases or by carriers of that organism, and particularly if they follow the same path after expulsion, the difficulty in visualizing direct mouth-to-mouth transfer is equally great. It may well be that, in view of the copious secretion from the nose in a cold and its tendency to increase in measles and influenza, there are many more virus particles available for expulsion, and that, besides being present in the nose, these particles occur in the anterior region of the mouth instead of being mainly confined to the tonsillar region, as appears to be the case with carriers of bacteria. For this reason the expulsion of easily recognizable organisms by normal subjects whose anterior mouth flora had been increased many times by taking up 5 ml. of a suspension of *B. prodigiosus* in saline (the whole of the growth on an agar slope after 24 hours' incubation being played) was studied in the same manner as with the carriers streptococci.

The results are given in Table III, from which it will be seen that the artificially infected mouth expels many more

TABLE III.—Average Number of Colonies per Person Isolated Before and After Instillation of *B. prodigiosus* Culture into the Mouth

organisms than the normal, the majority of them being the indicator organisms. The contrast between such a person and the streptococcal carrier is very marked indeed. Nevertheless, the same general principles apply. The great majority fall downwards out of harm's way, and, even with the larger numbers of organisms available, only by the more violent methods

would it be possible to infect the nasopharynx of another person on the same level and only 12 in. (30 cm.) away. This may possibly explain the failure of attempted transmission of influenza during the 1918 epidemic. It is possible, however, that in view of the increase in the number of available organisms, infected droplet nuclei may be commoner than in the bacterial infections.

Contamination of Person and Surroundings

Whether patients with virus infections of the nasopharynx can contaminate their person and surrounding objects has not been determined experimentally, but mere observation of a person in the throes of an acute cold should convince even the most sceptical that the virus is distributed over most of his person and surroundings. There is probably less contamination in influenza, but the prodromal stage of measles may be equally severe. For this reason the following experiments were performed.

Normal subjects had about 1 ml. of a suspension of *B. prodigiosus* instilled into their nostrils four times in the course of an hour and, by the application of soap or small quantities of sneeze-powder, the condition of the nose was made to resemble in some degree that of a person with a cold. The same subjects, but on different days, took cultures into their mouths (twice in the course of an hour) and on other occasions into both nose and mouth. While in this condition they wore a sterilized laboratory coat with pieces of sterile lint, 1 in. (2.5 cm.) square, pinned on in various strategic situations. They then proceeded to carry on with their ordinary occupations around the laboratory.

After an hour the patches were removed, placed into phials containing 5 ml. of broth, and, after shaking, 1/2 ml. of broth in each phial was spread over the surface of a well-dried agar plate. After incubation of the plates for 48 hours at 26° C. the number of *B. prodigiosus* colonies was determined. This figure was multiplied by ten to account for the dilution, giving the total population on 1 sq. in. (6.45 sq. cm.).

Immediately after the removal of the lint squares the coat was taken into a room 8 ft. (244 cm.) by 7 ft. (213 cm.) and 9 ft. 6 in. (290 cm.) high in which seven agar plates were disposed—two on the floor, two on stools 2 ft. (60 cm.) high, two on the bench 2 ft. 6 in. (75 cm.) high, and one on the window-sill 3 ft. (90 cm.) from the floor. The coat was then shaken twice with only moderate vigour. The room was now shut up and left for one hour. The plates were then covered, incubated for 48 hours, and the number of colonies of *B. prodigiosus* determined. For control purposes a similar series of plates were exposed for one hour before the experiment. The room was carefully washed and aired between each experiment.

From Table IV, in which the results are given, it is obvious that when the nose contains many organisms, even for a short period of time, they have no difficulty in reaching and contaminating the clothing of the subject during the ordinary activities

of the day. When the organisms are only in the mouth there is rather less contamination. On the clothing being shaken in a small room there was detectable contamination of the air by the indicator organisms. The results varied somewhat with the subject, the clothing of subject A being more heavily contaminated, while the air of a small room contained more organisms.

It must, however, be borne in mind that in these experiments the subjects were under observation for only one hour, that the organisms instilled into the nasopharynx very quickly disappear, and that the amount of nasal excretion was usually much less than that met with in acute infections. For these reasons the actual number of organisms detected is probably much smaller than the number of virus particles which might have been picked up had the individuals been clinically infected and a suitable technique been available for isolation of the virus.

Mechanism of Transfer from Person to Person

The experiments in the preceding sections show that if the number and location of virus particles in the nasopharynx of a patient in the acute phase of infection bear any resemblance to the number and location of the indicator organisms used in these experiments, the path they follow when travelling from donor to recipient is probably very similar to that followed by the bacteria under consideration in the first part of this paper, the indirect route by way of contamination of the person's clothing and surrounding objects probably being more important than direct mouth-to-mouth transmission.

Consideration, however, of the epidemiology of these infections shows that the release into the atmosphere of the concentrated output over several hours—an apparent prerequisite for the production of further cases of bacterial infection—is by no means necessary in the case of the viruses. For it is hardly necessary to do more than refer to the extremely rapid spread of colds and influenza following their introduction into islands and other isolated communities, while it would be possible to quote several instances from Panum which demonstrate the exceedingly slight contact necessary for the dissemination of measles. It is probable that this is due to a much greater output of infectious particles by persons with acute virus infections, aided by the fact that the virus is present in the nose. For this reason, not only do the surroundings become very heavily contaminated but also the atmosphere in the neighbourhood as well.

There is even a possibility that the person and clothing of others in the vicinity of the patient may become polluted either by droplets falling thereon direct from the patient or by virus particles released into the atmosphere after the buccal and nasal secretions on the person or bedding of the patient have dried. Such persons may become temporary "carriers" in the sense that the virus is on their clothing and not in their throats. In this condition they may convey infection to others at a distance. There is some epidemiological evidence in support of this.

While investigating an outbreak of influenza A in Alaska in 1935 two passengers and a pilot left Fairbanks on April 8 by aeroplane for Kotzebue, where they stayed for several days. The former place had had influenza since Jan. 15, and the latter was in the throes at the time of their arrival. They then proceeded by plane to Point Barrow, arriving on April 15. The Eskimos there became infected, though none of the travellers was infected in any way (Pettit, Mudd, and Pepper, 1936).

During the influenza epidemic in the Falkland Islands in 1935 the supply ship, S.S. *Lafonia*, left Port Stanley on Aug. 30, two members of its crew having been landed on Aug. 28 sick with influenza. "The hands themselves all seemed fit except for slight colds." On Sept. 2 she touched at a port in West Falkland, where "an epidemic of influenza broke out and spread to each place visited by the mail officer from the ship" (Cheverson, 1937).

Isolated communities such as Spitzbergen (Paul and Freese, 1933), Tristan da Cunha (Barrow, 1936), or the settlements in the Arctic north of Canada have very little respiratory infection so long as they remain isolated from civilization, but when contact with the outside world is re-established, usually by boat, the inhabitants suffer from severe colds. As a rule no information is given as to the state of the immigrants, although it may be assumed that they had had contact with colds some time previously. Hirsch (1883), however, mentions that they are usually free of infection at the time of arrival, and Heinbecker and Irvine-Jones (1928), describing an expedition to Baffin Land, mention that "it was not necessary for any member of the expedition to have an acute respiratory infection for the malady to appear amongst the natives."

A third instance may be quoted from the Reverend K. Macaulay (1764), who landed on St. Kilda in a spirit of scepticism that healthy people could carry colds, but to his immense surprise colds duly made their appearance amongst the islanders three days later. The same author mentions that some of His Majesty's soldiers landed on Hirta, "and although the natives gave them no manner of assist-

ance" (which was not surprising, for it was the year of Culloden). "at the same time, it is certain . . . that the cold described above attacked them with immense fury."

In the case of measles somewhat similar evidence may be cited from Panum (1939).

"Three weeks before Whitsunday, the provincial surgeon was summoned to Kvalvig, where a severe epidemic of Krujv was prevailing, and he had to spend the night in the village. In the house in which the surgeon slept the measles broke out exactly 14 days after his arrival. No other occasion than his visit could be assigned for the outbreak of the disease, since no resident of Kvalvig had been in any suspected place, and particularly none of those who lived in the house that was first attacked, and since no other stranger from any affected or suspected places had been in the village. . . . To Midtvaag, in Vaaga, the measles came, so people said, with the midwife, who had passed several days with the measles patients at Steegard. The woman had had the disease herself in Denmark. In all the houses in which the midwife had been, they said, the measles appeared 14 days later; and a girl who washed the midwife's clothes immediately after her arrival was the first who took the measles in Midtvaag."

Thus an aeroplane with three individuals on board, coming from an infected locality, and a mailman from a presumably infected ship, conveyed influenza; the arrival of ships with no apparent infection and the landing of an uninfected clergyman and a party of uninfected soldiers were followed by outbreaks of common colds; and the visit of a surgeon and a midwife, both free from infection themselves but from infected localities, caused measles in other communities. It is arguable that the immigrants were carriers and infected the new community, not necessarily by direct mouth-to-mouth transmission of the virus but indirectly by way of their clothing. If carriers of viruses have no more particles available for distribution than have carriers of streptococci the transmission of virus may be very difficult to achieve without very close and intimate contact. For this reason the alternative suggestion is equally plausible—that the virus was present on the boat or amongst the belongings of the travellers owing to contact with previous cases, and that a sufficient number of particles were released when the clothes were shaken or luggage was unpacked in the new community to cause infections amongst any susceptibles present. In this connexion the observation by Marshall, the surgeon of Shackleton's expedition, that after the party had been completely isolated for many months and was free of infection an outbreak of catarrh followed the opening of a new bale of blankets, is of some importance.

Thus it would seem probable that the person-to-person transfer of virus particles may occur if violent methods of expulsion are employed, but that an indirect route in which the buccal and nasal secretions dry on the person and surrounding objects and reach the atmosphere by shaking, etc., is more probable. Whatever the mechanism may be, there can be little doubt that it is extraordinarily efficient and that, in contrast to the bacterial infections, minimal degrees of contact are all that are necessary. Indeed, the virus may be conveyed to others separated in time and space by considerable distances.

Discussion

It is not suggested that anything more than a working hypothesis has been put forward to account for the spread of the infections under consideration, and it is possible that as further evidence is obtained it may have to be modified or even abandoned altogether. It would seem, however, that the methods by which both bacterial and virus infections are disseminated are essentially similar.

The former evidently requires the slow building up of the carrier rate, and not until a sufficient number of carriers have been assembled can actual clinical infections appear. The virus infections, on the other hand, probably require the presence of individuals carrying virus in the latent form. The frequency with which such persons occur in the population is still a matter for speculation. When the external conditions are right (and what these conditions may be we do not know, though weather may play its part) the virus is mobilized, producing clinically recognizable infection.

In the transfer of infection from person to person, it would seem that much the same mechanism is at work in both bacterial and virus infections. Probably little infection is transferred direct from mouth to mouth, the majority of secondary

infections being produced by bacteria or viruses which have followed a circuitous route. In the case of bacterial infections, possibly because very few infectious particles are expelled, this occurs only when the concentrated output over several hours can be suddenly released into the atmosphere. But in the virus infections, possibly because more infectious particles are present, such concentration is unnecessary and infection can be transferred with extreme ease and as a result of only slight degrees of contact.

In view of this the prevention of virus infections by ultraviolet light or aerosols may prove to be extremely difficult, whereas it may be much easier in the case of bacterial infections. This should be borne in mind before expensive installations are contemplated.

AMPHETAMINE AND CAFFEINE CITRATE IN ANOXAEMIA

BY

R. C. BROWNE, B.M., M.R.C.P.

Late Squadron Leader, R A F V.R.

and Strumza (1939a, 1939b) showed that the very large of amphetamine of 0.2–0.4 mg. per gramme of body delayed the onset of unconsciousness in anoxaemic guinea-pigs, and also that doses of a similar order revived dogs which were comatose from the same cause. In another series of experiments they found that, although caffeine citrate did not increase a dog's resistance to anoxaemia, as measured by the time of onset of unconsciousness, both ephedrine and amphetamine did so, but excessive doses of the latter augmented the depression brought on by oxygen lack. In men, however, who were breathing an oxygen-nitrogen mixture which simulated climbing from an altitude of 10,000 ft. to about 24,000 ft. (3,000–7,300 m.) in 40 minutes, Knehr (1940) and others were unable to demonstrate any improvement in coding and calculating after subcutaneous injections of 20 mg. of amphetamine.

Early in the recent war it became necessary to investigate the actions of amphetamine (benzedrine—Menley and James) and caffeine upon anoxaemia, and a small-scale attempt was made, therefore, to link up a study of the objective performance of anoxaemic airmen with a survey of their symptoms in order to give a double assessment to the action of these two drugs.

Method

In the present investigation five pilots and one ground instructor (who soon afterwards became a pilot) were the subjects for the test on performance, and six pilots and two ground instructors for the experiment on the symptomatology. The nature and purpose of the tests were carefully explained

to every man, and it was pointed out that it was no part of the investigation to make them ill, and that they were to mention anything untoward which they noticed. At the same time, however, care was taken not to suggest any of the possible symptoms of anoxaemia either by telling them what to notice or by direct question afterwards.

The test used was to keep a Link, or instrument flying trainer, on an even keel and a set course for 45 minutes when it was going through the motions of an aircraft flying in bumpy air. This machine is the standard synthetic training device for teaching instrument or blind flying in the R.A.F., and it forms one of the nearest copies of real flying which can be numerically scored. It is fitted with the same controls and dashboard instruments as a real aircraft, and can assume the positions of a machine which is climbing, diving, banking, or turning. Movements of the controls, moreover, cause corresponding changes in the attitude of the fuselage and in the readings of the blind-flying instruments. There is also a mechanism which makes the machine assume rapid changes in attitude like those of an aircraft which is flying in rough or bumpy air, and it was considered that the continuous correction of these deflections (which were constant in number and amplitude from test to test) provided a suitable task for an experiment of this kind. The errors in making these corrections were measured by three mechanical integrators (one for each dimension) which gave numerical readings upon three dials, and which were all driven by the same constant-speed electric motor. This mechanism automatically stopped every two minutes, and it took about a minute to note the readings and reset the dials to zero, so that repeated samples of the performance could therefore be obtained at three-minute intervals.

The subjects were made anoxaemic by breathing, through a standard Service telephonist's gas-mask (Fig. 1), an oxygen-

FIG. 1.—Subject wearing Service telephonist's gas-mask. 1, Expiratory valve. 2, Mica valve, closing on expiration. 3, Microphone.

nitrogen mixture containing 11% of the former, which represents an altitude of about 16,200 ft. (5,000 m.). Gas of this composition was fed from large cylinders through a reducing valve and flowmeter into a 10-litre breathing-bag which was slung from the side of the trainer (Fig. 2). A standard time

FIG. 2.—Link trainer fuselage with breathing apparatus. 1, Subject in telephonist's gas-mask. 2, 10-litre self-collapsing breathing-bag. 3, Supply pipe from gas cylinders. 4, Flexible rubber hose to mask.

of five minutes was taken to change over from breathing air to this mixture. The mask was fitted with a microphone and connected to the breathing-bag by a piece of wide-bore corrugated hose-pipe, and in its base was a light mica valve which shut on expiration, and which was fitted in such a position as to

reduce the dead space to a minimum, since this might have held a relatively high concentration of CO_2 and thus made the subjects resistant to oxygen lack. Breathing with this apparatus was comfortable, as the bag had a tendency to collapse, which eliminated any inspiratory negative pressure. Preliminary experiments showed that the pressure in the mask never fell below atmospheric, and that wearing it and breathing air had no effect on the performance of the test. There was complete two-way telephonic communication between observer and subject, so that information was gained at once about any symptoms which arose. In one set of tests amphetamine 15 mg was given 3½ hours before starting, and in the other caffeine citrate 10 gr. (0.65 g.) 1½ hours before. In both cases the tests with the drug were compared with similar experiments when the subjects were given inert tablets. Since it was expected that there might be some improvement with practice it was decided that half the subjects should have the active preparations on the first of the two trials and the other half on the second, and the airmen were therefore allocated at random to one or other of these arrangements.

Results

(a) *Objective Performance*—Table I shows the number of errors made by the group of six subjects, both with and without the drugs, in three time intervals of 15 minutes each. Since the integrators were read every three minutes each figure shown is therefore the mean of ($3 \times 6 = 18$) observations. With amphetamine there is a small consistent improvement of 1.9 errors in the first 15 minutes, of 0.4 in the second, and of 1.6 in the third. The overall difference in favour of this substance is, however, only 1.7 ± 1.63 errors, which may easily be a

TABLE I.—The Mean Number of Errors made by a Group of 6 Anoxaemic Subjects with and without Amphetamine and Caffeine Citrate

Time, Minutes	0-15	16-30	31-45
Control	24.0	25.6	26.4
With amphetamine	22.1	24.4	24.8
Control	21.9	26.2	27.4
With caffeine	23.5	25.5	27.1

chance finding. 10 gr. (0.65 g.) of caffeine citrate had no effect on performance, since in the first 15 minutes 1.6 more errors were made with the drug, but in the last 30 minutes 1.0 fewer. There is therefore no evidence, within the limits of this small objective experiment, that either amphetamine or caffeine citrate significantly affects the performance of anoxaemic men.

(b) *Symptomatology*.—Table II and Fig. 3 show the symptoms in the order of frequency in which they were reported, both in the control tests and after the administration of the two drugs. Sleepiness is the commonest in the control series, with 0.776 complaint per hour, being rather more than 2½ times as common as the succeeding dyspnoea, with 0.302 complaint per hour. Various types of visual disturbance are next in order of frequency with 0.135 complaint per hour, and these include dim, misty, blurred, or yellow vision, which usually started at

TABLE II.—The Effect of Amphetamine and Caffeine Citrate upon the Relative Frequency of the Symptoms of Anoxaemia

Symptom	Number of Complaints per Hour of Exposure		
	Control Tablets	Amphetamine	Caffeine Citrate
Sleepiness	0.7760	0.2670	0.5420
Dyspnoea	0.3020	0.3140	0.7000
Visual	0.1350	0.1800	0.2170
Cold limbs	0.0397	0.0397	0.0000
Annoyance	0.0448	0.0448	0.1090
Headache	0.0448	0.1800	0.0000
Faintness	0.0448	0.0397	0.2170
Volubility	0.0448	0.0448	0.1090
Subjective change in ease of test	0.0344	0.0448	0.1090
Euphoria	0.0000	0.1800	0.0000

the edge of the visual field. Next in order of frequency come complaints of cold limbs and manifestations of annoyance from those subjects who were naturally a little irascible—notably from a stocky fighter pilot who had been a nuisance to his superiors during his training and “a bad influence on the rest of the course,” but who, fighting with distinction in the Battle

of Britain, was decorated with the D.F.C. Generalized headache, faintness, volubility, and a subjective feeling that the test was more or less easy to do were next noted in that order.

Amphetamine 15 mg., given 3½ hours before exposure to the anoxaemia, significantly reduced sleepiness by 0.509 ± 0.02 complaint per hour. This drug, however, seemed to increase headache by some 0.135 ± 0.034 complaint per hour. Notwithstanding the fact that chance cannot definitely be ruled out here, it is reasonable to expect this to happen, since both amphetamine and anoxaemia probably tend to increase the blood supply to the brain, thus doubly increasing the calibre of the cerebral vessels, upon the stretching of which there is some evidence (Cohen, 1939) that headache of this nature depends. A similar summation of action may explain the euphoria which was noticed only when amphetamine and anoxaemia coincided.

FIG. 3.—The effect of amphetamine and caffeine citrate upon the relative frequency of the symptoms of anoxaemia.

Although caffeine citrate 10 gr. (0.65 g.) 1½ hours before exposure to the anoxaemia produced an insignificant diminution in the complaints of sleepiness, it caused a slight but consistent increase in all the other symptoms upon which it acted at all, producing the most notable increases in the number of complaints of dyspnoea and faintness. Many of the subjects, indeed, felt positively ill when they were made anoxaemic after taking this drug. Although, technically speaking, the differences caused by it upon the individual symptoms are not significant, it is difficult to avoid the conclusion that it made these airmen feel worse than if they had taken nothing at all—and this with a dose well within the normal therapeutic range. In this part of the experiment the subjects were made anoxaemic for a total of 23 hours with the control tablets, for 22½ with amphetamine, and for 9 with caffeine.

Discussion

This small experiment once again emphasizes the difference between the objective and subjective actions of a drug, and the point is illustrated by the slight effect of amphetamine upon performance compared with its relatively large action in diminishing sleepiness, which was the commonest symptom of anoxaemia noted. It is a little surprising that there was not a more marked action upon performance, since it is reasonable to suppose that a diminution in sleepiness would also tend to lessen the number of errors in the test due to this cause. There is, however, an element of “what is gained on the swings is lost on the roundabouts,” in that amphetamine may increase visual symptoms, headache, and euphoria.

The balance of evidence in the case of caffeine, so far as this experiment goes, suggests that it should not be given to men who are likely to become anoxaemic, and vice versa, since it does not seem to improve their performance and, showing a small but consistent increase in a number of diverse symptoms,

makes some of them feel frankly ill. This naturally raises the question whether it is wise to give it to patients who are anoxaemic from clinical causes.

To make them worth using under wartime operational conditions drugs like these must have a very obvious beneficial effect with as few drawbacks or as small a "cost" as possible—and especially when the man who takes them is in charge of a highly complicated piece of machinery such as an aircraft.

It is worth noting here that the relative frequency of the symptoms of anoxaemia in this paper differs somewhat from that set out in two other recent descriptions (Armstrong, 1939; Matthews, 1945), and the three are compared in Table III. The

TABLE III.—A Comparison of Three Recent Descriptions of the Symptoms of Anoxaemia (given in Order of Frequency) for Approximately the Same Altitude

Armstrong	Matthews	— Present Paper
Headache	Reduced night vision	Sleepiness
Altered respiration	Fatigue	Dyspnoea
Psychologic impairment	Headache	Visual symptoms
Euphoria	Errors of judgement	Cold limbs
Sleepiness	Indifferent mental condition	Annoyance
Lassitude	Reduced capacity for physical work	Headache
Fatigue		Faintness
		Volubility
		Subjective change in job

differences may perhaps be in part due to nomenclature rather than to fact, and some may be attributed to the different times spent at a particular level. There may also be less tendency for symptoms to be noticed in an aircraft, or indeed for them to occur, because the external environment is more demanding than the internal and, in the case of sleepiness, there is more to keep a man awake in the air than there is in a laboratory set-up on the ground, where he is under close and safe observation.

Summary

The effects of amphetamine and caffeine citrate upon the performance and symptoms of a small number of anoxaemic airmen have been investigated. Anoxaemia was produced by breathing an atmosphere of 11% oxygen and 89% nitrogen, equivalent to an altitude of 16,200 ft. (5,000 m.). Doses of 15 mg. amphetamine were given 3½ hours and 10 gr. (0.65 g.) caffeine citrate 1½ hours before exposure to this.

Keeping a standard instrument flying or a Link trainer straight and level on a set course for 45 minutes was the test used. A record of the performance was maintained by three mechanical integrators, and of the symptoms by an observer in continuous two-way telephonic communication with each subject.

Amphetamine produced a consistently small but technically insignificant improvement in performance, and caffeine citrate was fully without effect.

Amphetamine reduced the incidence of sleepiness by nearly three times, but had no beneficial effect upon the other symptoms of anoxaemia. It may have increased headache and euphoria. Caffeine citrate may have slightly reduced sleepiness, but it seemed to accentuate all the other symptoms.

This investigation was commissioned by the Flying Personnel Research Committee, and acknowledgements are due to Air Marshal Sir Harold Whittingham, K.C.B., K.B.E., late Director-General, R.A.F. Medical Service, for permission to publish this paper; to Prof. L. J. Wits for his advice and criticism; to Dr. Edwin Schuster for making the integrators; to the Medical Research Council for a personal grant; and to Messrs. Menley and James for a supply of benzedrine.

All civilians repatriated to Scotland from former enemy-occupied territories are now entitled to free medical treatment for any disability whatever for a period of six months from the date of landing. In a circular to local authorities, the Department of Health for Scotland states that treatment, which includes optical and dental attention, should be obtained wherever possible through the Emergency Hospital Service. After six months, repatriates will receive treatment only for illnesses or disabilities accepted by the Ministry of Pensions as attributable to war operations over-seas or to the effects of internment. Similar arrangements have been made for England and Wales.

THOMAS AND HIS SPLINT*

BY

T. P. McMURRAY, M.Ch., F.R.C.S.Ed.

The war has brought once more to the notice of the surgical world the great advantage which can be obtained from the Thomas splint; its application is easily understood, and the full benefits of the splint follow on adherence to the advice of its designer. Hugh Owen Thomas, who devised the splint, was the descendant of a long line of farmers from Anglesey, in North Wales, where the family were very well known—not so much for their ability in farming as for their secondary and more spectacular occupation of bone-setting. This knowledge, or ability, or knack was apparently taught to every member of the family, the female members being equally active in the work with their brothers. Sixty or seventy years ago it would have been thought that a fracture or dislocation occurring in North Wales had been neglected unless one of the Thomases had been called in and had taken complete charge. This peculiar condition of affairs apparently caused no ill feeling among the local doctors, who seem to have become reconciled to it. Modern developments and improvements in medical training have gradually led to a virtual disappearance of these unqualified practitioners, although there is even to this day an elderly Miss Thomas who carries on the family tradition to a very restricted degree.

It is difficult, under modern conditions, to realize the power and influence which the bone-setter wielded at this time; he usually had a large following among the general public, who considered that the skill of the members of the medical profession was, in this branch of surgery, vastly inferior to that possessed by those who were supposed to have some mysterious gift for setting fractures and reducing dislocations. The public were encouraged in this belief not only by the claims of the bone-setter but in many instances by the teachings and writings of leaders of the surgical world. As an instance, Sir James Paget in his *Clinical Lectures and Essays*, published in 1867, described the skill and success of a particular bone-setter, and stated that by following the practice of the bone-setter, as outlined in the *Essays*, results could be obtained which were in every way superior to those which followed generally accepted surgical methods. This praise of the unqualified practitioner was a common feature of the surgical literature of the time, and Sir Benjamin Brodie, in his monograph *Bone-setters and Bone-setting*, praised the results obtained in joint disease by the manipulative practice of many of the group.

Evan Thomas

One of the Thomas family—Evan—decided, at the age of 19, to leave the Anglesey district and seek a wider field for the practice of his art in Liverpool. He hoped that on his arrival he would be able to start his work, but he soon found that the family reputation had not spread so far, and in order to make a living he went to work in one of the local foundries. His work here lasted only three or four years, and ceased because his increasing reputation in the treatment of the injuries of his fellow-workers enabled him to leave the foundry and devote his whole time to the art which he had learned as a boy. His reputation grew rapidly; patients came to him from every class of society; and in the midst of this activity he looked forward to the day when one or more of his sons would join him in his practice. He realized the disadvantages under which he worked without a medical training or qualifications, and determined that his five sons should not suffer similar handicaps. His eldest son, Hugh Owen, at the age of 21 became a medical student in Edinburgh, where he came under the instruction of Syme and Goodsir; later he was a student at University College, from which school he finally obtained his qualification in 1857. During his schooldays and later during the university holidays he helped in his father's practice—in fact, on one occasion during the father's illness he took control for a short period. Such were the conditions under which the boy grew up, not only seeing and learning his father's work but coming into contact also with the results obtained by the local surgeons and

* Delivered to the British Orthopaedic Association, December, 1945.

by many famous bone-setters of the day. It was natural to expect that during his medical training he would be brought to realize the superiority of the work of the trained surgeon over that of the unqualified and often ignorant bone-setters, but, unfortunately, the teaching given him on this particular subject by Syme, Spencer, Simpson, and Goodwin at Edinburgh University was no improvement on what he had learnt in his father's practice.

During his course at Edinburgh nothing impressed H. O. Thomas so deeply as the frequency with which amputation was the final stage in the treatment of inflammation and disease of joints. As a boy he had seen many similar patients treated conservatively, and apparently successfully, yet here in Edinburgh—the Home of Surgery—amputation seemed to be the invariable rule. Already the conviction was growing in his mind that such wholesale amputations could be avoided if conservative treatment were started early and carried out intelligently.

Hugh Owen Thomas in Practice

Following his qualification Thomas returned to Liverpool to help in his father's practice, and recognized that here he was seeing a more successful application of principles than he had seen while at the medical school. Unlike the curriculum for the training of a surgeon, there was no line of instruction for the bone-setter; each acted according to his belief, or because on occasion relief had been gained by some application or alteration of position of an injured or diseased joint. Many of the bone-setters were simply manipulators; some used massage alone; while others believed in the efficacy of various forms of poultices. Evan Thomas was essentially conservative in outlook, and never attempted to produce movements by means of forced manipulation. Sprained and painful joints were treated by comparative rest; this was obtained by covering the joint with successive layers of pitch plaster, which, fusing together, assumed the rigidity of cardboard. Pulleys and traction were freely used in the treatment of fractures, and when length and symmetry had been restored to the broken limb the position was maintained by well-padded splints. He taught his son that the ideal to be aimed at was restoration of alignment, and that without such perfect correction the result must be classified as failure. Father and son worked well together for a short time, but soon the young man began to make suggestions, and when these were repeated and elaborated the end of the partnership had to come.

After a rather heated parting with his father, Hugh started in practice in a neighbouring street and soon gained a following largely among those who had, formerly been treated by Evan Thomas. Hugh was always a general practitioner, being the doctor to several of the clubs and tontines along the docks. At no period of his life was he attached in any way to a hospital; all his practice and experience came to him as a club doctor, but his power of observation compensated for the absence of hospital experience. Within three years of starting practice he had built for himself a workshop fitted with the most modern tools and jigs, and here he spent most of his evening hours working, planning, correcting, and eventually perfecting his various splints. Just as in the case of the father so in that of the son, the success of his treatment led to constant additions to his work. Because of the inability of many of his patients to pay even the smallest fees he instituted a Free Sunday Clinic, which continued uninterrupted until the beginning of the war of 1914-18. As one would expect, he was not accepted by the surgeons of Liverpool; hard words were spoken on both sides, and only one—the late Rushton Parker—could see any good in his treatment or could refrain from criticism of his methods.

The Thomas Splint

So much for the man, and now I find myself faced with the rather difficult problem of describing his splint. Strictly speaking, there is no such apparatus as the Thomas splint; Thomas perfected at least 10 splints which are still widely used, but the one which is usually known as the Thomas splint was described by him as the *bed knee-splint*. The title indicates quite clearly the use or uses for which it was devised. The splint is extremely simple in its construction, being fashioned from one of three sizes of best round bar iron, iron being preferable to steel

because of its greater rigidity. The main portion of the splint is formed by two straight lateral bars which are joined above to an ovoid ring of the same metal approximating inferiorly where they meet in a W-shaped junction. The two lateral bars exactly bisect the ovoid ring, the curve on each side of the lateral bars being equal. The angle between the inner lateral bar and the ring during construction should be 120° when looked at from either the front or the back (Fig. 1). When the metal framework of the splint has been correctly constructed the padding and leather covering are applied; the padding consists of thin strips of felting which are stretched tightly round the upper ring, the amount of padding depending roughly on the age and development of the patient. The highest portion of the ring requires very little padding, a covering of leather usually being sufficient, but at the bearing points the felting is wound firmly round the groin bars, and tapers off on each side. The amount of padding used depends roughly on the size of the patient, but there is one important proviso—in a very fat patient it is not necessary to increase the padding greatly, as a very bulky mass would tend to retain moisture and so produce pressure sores. The length of the splint should be such that when applied to the patient the W-shaped end should extend at least 6 in. (15 cm.) beyond the foot.

FIG. 1—Left side bed knee-splint, right side calliper, showing metal skeleton of splints.

The introduction of the splint to the surgical world came at an extremely opportune moment; at this period, both in this country and in America, the belief in the inherent evils of immobilization of inflamed or injured joints was widespread. The teaching of the surgical schools was almost unanimous in affirming that the great cause of ankylosis was immobilization. Thus, in Couper's *Dictionary of Surgery* it is stated: "One thing almost essential to the production of ankylosis is the joint being kept motionless, and if persisted in will of itself bring on the changes which produce true or false ankylosis."

Again and again in the surgical literature of the time are these pronouncements given on the evils of rest and the benefits of frequent passive movements in the treatment of arthritis. The error of such teaching would seem to be obvious; the surgeons of the day had not the means of differentiating the various types of chronic arthritis, and, finding that passive movement was of advantage in some, they stressed their faith in it as a panacea for every type.

The simplicity of construction of the Thomas splint might tend to give the impression that here was an apparatus which had been rapidly designed, but, in fact, the exact opposite is true. At least six forms of splint were designed by Thomas before he evolved the final and simple bed knee-splint. I have seen many of these attempts, and it is interesting to realize that almost all the improvements and alterations to the splint which have since been devised were tried by Thomas and discarded on account of some mechanical defect. In the first description of the splint Thomas wrote that he had tested and tried it for ten years before bringing it to the notice of the profession—a test which is unfortunately not always followed by the sponsors of surgical procedures of the present time.

The Fracture Carriage.—The fracture carriage (Fig. 2) is one of the stages in the development of the bed knee-splint; many of the final parts of the finished splint are incorporated in this apparatus, but those that proved faulty were quickly discarded. In this fracture carriage the two straight lateral bars pass through a split in the anterior portion of the groin ring and are threaded along the bars until they come to a notch on its outer and inner margins. From there they pass directly down to be clamped to a transverse bar beyond the patient's foot. Alterations in the size of the ring were provided for either by

altering the sites of attachment of the lateral bars or by opening or closing the groin ring, which was made with a male and female portion similar to the conjurer's ring. As an addition, there is the foot-piece, which maintains its position by pressure

of its two lateral transverse portions on the side bars. The method of extension, or rather of fixation, is the same as in the bed knee-splint, the theory of complete and prolonged immobilization being the basic principle of treatment in both. Other stages of the splint on the way to the final design include a hinged groin ring, movable in all directions, and curving of the lateral bars, each of which was rapidly discarded.

Application of the Splint

The Thomas splint is easily applied, and owing to its simplicity of design there is little which can get out of order or cause anxiety in the course of treatment. The first essential in the use of the splint is the correct fitting; if employed in large numbers a graded series of splints of sizes differing by 1 in. (2.5 cm.) should be kept in stock. If such a large stock is not maintained the patient should be measured, and an accurately fitting splint applied (Figs. 3 and 3A). It would be unreasonable to blame the splint for troubles which might develop unless these details are remembered (Fig. 4). In measuring the patient the circumference of the thigh is taken just below the gluteal fold; to this measurement $1\frac{1}{2}$ in. (3.8 cm.) is added to allow for the obliquity of the ring and the

FIG. 2.—The fracture carriage.

kness of the felting. The length is measured from the groin point at least 6 in. (15 cm.) beyond the foot with the knee y extended.

When the correct size of ring is obtained it is threaded over the foot, leg, and thigh until it comes to rest in the area of normal weight-bearing in the ischial region. In this position the padded inner posterior portion of the groin ring is placed directly under the ischial tuberosity, and cannot slide from this area owing to the snug fit of the outer portion of the ring against the upper and outer portions of the thigh.

In action the splint obtains its results by complete immobilization of the injured or inflamed tissues. In Thomas's hands and in those of many of his successors the fixation was obtained by the use of adhesive strapping applied directly to the skin of the leg and thigh. If the correct type of strapping is used there is no irritation of the skin, and the strapping will remain firmly adherent for at least two or three months. The fixation of the extensions to the end of the splint is effective only when the ring is firmly placed on the ischial tuberosity, at which point this counter-pressure need not produce undue pressure or skin injury so long as simple rules of nursing are carefully followed.

The routine is not difficult; the skin under the ring is moved and rubbed gently with methylated spirit and then dusted with some non-irritating powder. This routine, which at first must be followed every two hours, is sufficient to prevent the formation of pressure sores, and the occurrence of this complication must be looked upon as a grave nursing error.

With the splint applied in this way the whole thigh and leg are supported on a posterior metal splint which is slung from the lateral bars. These slings are pulled tight until at least two-thirds of the thigh lies in front of the side bars of the splint, thus retaining the normal anterior curve of the femur (Fig. 5). A pad of wool is placed behind the knee to keep the joint in slight flexion and, by varying the position of the straps round the lateral bars, internal or external rotation of the limb in the splint can be prevented.

FIG. 3

FIG. 3.—Thomas splint in correct position before applying the posterior and side splints.

FIG. 3A.—Essential requirements for the treatment of fractured femur by Thomas's method.

FIG. 4.—Incorrectly applied splint. Most of limb below level of splint bars; extension tapes loose; no support for back of leg and thigh. Hyperextension of knee; leg externally rotated. Ring of bed knee-splint half-way down thigh.

FIG. 5.—Correctly applied Thomas splint with lateral and posterior metal splints, the bandaging being left off to show the correct application.

The Thomas Splint in War

Four years after Thomas first described the bed knee-splint and its uses the Franco-Prussian War of 1870 broke out. Thomas wished to give his splint to the French for use in their hospitals, and was able to get one into the hands of the chief of the Medical Services in Paris. He was thanked politely for his offer, but it was regretted that the splint would not be of any practical value.

At the beginning of the 1914-18 war the use of the Thomas splint was confined almost exclusively to the Liverpool area, and its advantages had not been realized by the Army Medical

Services After two years of war, when the death rate from gunshot wounds of the femur had been found to be in the neighbourhood of 80%, the splint was wholeheartedly adopted largely owing to the enthusiasm of Robert Jones. Demonstrations were given to medical officers and orderlies and as a result of its universal adoption the death rate from compound fractures of the femur was reduced to 23%.

In the years between the wars instructions in the use and application of the Thomas splint were included in the manual of the Royal Army Medical Corps teams for the immediate application of the splint were formed and it was generally considered that this bugbear of war surgery had been overcome.

In the recent war the Thomas splint was again used in most cases of fracture of the femur but unfortunately its full advantages were not always obtained. In the R.A.M.C. the Thomas splint was supplied in only three sizes of ring so that a correct fitting as described by Thomas was as a rule an impossibility.

In his original description of the splint Thomas stated that if, in an emergency, a splint of the proper size could not be supplied a splint with a much larger ring could be used as a temporary measure until a suitable splint could be obtained (Fig 6). In order to keep the ring of such a splint in apposition to the ischial region a large pad of wool or felt was placed between the great trochanter and the outer border of the ring, but such an arrangement must be only temporary, and must not be considered as permanently efficient or satisfactory.

With only three sizes of ring the splints in the Army hospitals were, as a rule temporary makeshifts which could not give the complete fixation

which was essential in the treatment. In the other great branch of wartime medical service, the E.M.S. hospitals, the condition in regard to Thomas splints was equally unsatisfactory. The rings of the splints were badly designed, the groin rings were not fashioned on the Thomas pattern, two curves meeting at a sharp angle in each half of the groin ring, the padding was poor, and after prolonged use the metal of the ring was found to be pressing almost directly on the skin of the ischial area. The Thomas splint is such an outstanding contribution to the treatment of injuries and diseases of the lower limb that the specification of Thomas should be closely followed.

THE IMPORTANCE OF AUTOREGULATION IN NITROGEN METABOLISM

BY

S. M. LEITIS, M.D.

Until recently it was believed that the regulation of metabolism was effected by factors outside the process, the regulating factors were believed to be nerve impulses and hormones. The work of the American physiologist Soskin and of Soviet investigators showed that the products of metabolism play an important part. They regulate metabolic processes and act directly on them, and at the same time they influence the nervous system and the internal secretory glands. This effect we call autoregulation. Here are two examples to illustrate the point.

(a) When 50 to 100 g of glucose are administered to an animal or a human being, within 30 to 40 minutes the sugar level in the blood rises 50-60% above its initial value, if the same quantity of glucose is then administered for a second time the level of sugar in the blood is raised little or not at all. It appears that the increased concentration of sugar caused by the first injection facilitates the

formation of glycogen in the liver. When the second injection is given, therefore, it is retained almost entirely in the liver. The regulation is affected by the sugar in accordance with the concentration obtained.

(b) The injection of fat is accompanied by an increased concentration of the fat and the metabolic product—ketone bodies—in the blood. This is usually the case when the fat concentration and the ketone bodies in the blood are at the normal level. If the initial level of the fat and ketone bodies is above normal the introduction of further fat not only does not increase the existing concentration but, on the contrary, reduces it to the normal level. An increased concentration of fats and ketone bodies increases their retention and consumption in the tissues. It therefore follows that fats and the products of their metabolism are factors that regulate the metabolism.

The Mechanism of Autoregulation

Research carried out for several years has enabled us to study the laws governing the autoregulation of nitrogen protein metabolism and to show its importance for therapeutic purposes. We observed two basic phenomena. First, when proteins are introduced into the stomach or when the products of nitrogen metabolism are introduced internally (uric acid, urea) the amount of nitrogen metabolites—the so-called nitrogen content—in the blood increases. When the nitrogen content of the blood is at its greatest (hyperazotaemia) there will be no further increase if the same substance is again administered, but, on the contrary, there will be a decrease. Secondly, when the initial state is one in which there is a high nitrogen content of the blood (as in certain pathological conditions) the introduction of protein or the products of its metabolism again causes a decrease and not an increase of the nitrogen content. These facts show that a degree of concentration of the nitrogen metabolites in the blood determines and regulates the direction taken by azotaemia.

Further investigations showed that the introduction of a normal quantity of protein and its products led to increased splitting of protein in the tissues (proteolysis), this increases the nitrogen content of the blood. If there is increased proteolysis of the tissues (e.g., in cases of starvation, phosphorus poisoning, fever) the use of proteins decreases the proteolysis. This is why the introduction of protein and its metabolites reduces the nitrogen content in the blood. It is important to note that of the two groups which make up the nitrogen content—urea and non-urea—the urea checks an increase of nitrogen content.

Application in Kidney and Liver Disease

Kidney diseases (nephritis) are often complicated by uraemia, which results from a poisoning of the organism by the products of the non urea component of nitrogen metabolism. The urea is not toxic. If as I have said, the increase in the quantity of urea in the blood prevents an increase in the nitrogen content, then, first, the greater amount of urea present in the blood in cases of nephritis may be regarded as an adaptation preventing an increase in the toxic products of nitrogen metabolism, and, secondly, it is possible to introduce urea in cases of nephritis to reduce uraemia poisoning. Our experiments on rabbits artificially infected with nephritis and on rabbits with the kidneys removed show that the introduction of urea reduces the poisoning and lengthens the lives of the sick animals. The investigations of Dr Brook, of Kharkov, showed that the use of urea had a good effect in the treatment of nephritis. In some liver complaints there is an increase in the nitrogen metabolism in the blood. It was formerly regarded as dangerous to give patients suffering from liver complaints foods containing large quantities of protein. Now that we know the mechanism of autoregulation we may assume that the protein is more likely to be beneficial to these patients. Prof Pevsner of the Clinic of Dietetics has been successful in the use of protein diets in liver complaints. In treating cases of tuberculosis, when there is an intensive disintegration of protein in the organism, the use of large quantities of protein in the food decreases this disintegration and reduces the nitrogen content of the blood.

It has been shown that one of the ways of effecting autoregulation in nitrogen metabolism is the direct influence of the nitrogen metabolites on proteolysis in the tissue. The other way is the effect of nitrogen metabolites on glands of internal

FIG 6—Shows use of the Thomas splint with too large a ring used only in an emergency and for a short period

secretion (hypophysis), in particular on the hormones concerned in protein metabolism. Both of these are very weak in animals that have had the hypophysis removed. When such animals have increased nitrogen content in the blood the introduction of protein or nitrogen metabolites causes a further increase; the same effect is seen when further doses of these substances are administered. On the other hand, healthy people and animals excrete the hormones of protein metabolism of the hypophysis in their urine.

Conclusion

In the light of the foregoing data the mechanism of auto-regulation is apparently the following: when there is an increased quantity of nitrogen metabolites in the blood there is a reduction in the disintegration of protein in the tissues. As a result of the surplus production of the hormones of protein metabolism of the hypophysis, synthetic processes become active in the nitrogen metabolism. All this leads to a reduction of the increased concentration of nitrogen metabolites in the blood and to the reduction of the azotaemia to normal.

The establishment of this new law shows the way for a new method of dietetics and for the functional diagnosis of diseases in which protein metabolism is disturbed.

AGRANULOCYTOSIS DUE TO NOVALDIN (NOVALGIN)

BY

W. HARDING KNEEDLER, M.D.

Associate in Medicine, Jefferson Medical College,
Philadelphia, U.S.A.

Among the drugs responsible for agranulocytosis, novalgin—or novaldin, with which it is identical—has received comparatively little notice. This drug is essentially sulphonated aminopyrine, the sulphonation serving merely to increase solubility but not changing the chemical structure in any important respect. Therefore the two drugs would appear to be equally dangerous. The similarity of action is confirmed by a report (Benjamin and Biederman, 1936) of a test dose of novaldin having been given to a patient known to react to aminopyrine with agranulocytosis. There was a mild haematologic and symptomatic response of this nature when novaldin was administered.

Novalgin was originated in Germany, and has been sold under this name by the Bayer company and its subsidiaries, except in the U.S.A., where it is produced under the name "novaldin" by the Winthrop Chemical Co. The drug has in the past been sold without warning of its true nature or potential danger. I have repeatedly seen it advertised to the general public in newspapers in the Far East without caution regarding its use. At the present time the drug is sold with adequate warning in the U.S.A.

Agranulocytosis due to novalgin (Das Gupta, 1936; Donnison, 1936) and novaldin (Blake *et al.*, 1935; Klumpp, 1937; Moloney and Vidoli, 1943) has been reported in the literature five times. All of these cases have been fatal. The case recorded herewith is the first non-fatal one; and, I believe, the first reported instance of agranulocytosis in a haemophilic.

The treatment of agranulocytosis by penicillin has been reported by various authors (Tyson *et al.*, 1946; Boland *et al.*, 1946), and has doubtless been used more extensively for this condition than the number of reports indicates. Although its rationale is evident, since death in agranulocytosis is commonly the result of overwhelming sepsis, it nevertheless seems worth while to call attention to it as a valuable therapeutic procedure.

Case Report

Mr. W., a true haemophilic, aged 52, suffered from frequent severe pain due to haemorrhages into various joints. Since this pain was not satisfactorily controlled by other drugs, limited use of novaldin was allowed. During a period of six months he took a

total of 30 tablets of 5 gr. (0.32 g.) each, seven tablets being taken in the two weeks before onset of acute symptoms; none of the drug was given after fever developed. Several days before onset of fever he complained of a general feeling of malaise, which he found hard to analyse. On Feb. 26, 1945, he developed a fever of 102° F. (38.9° C.), with no other definite symptoms. On Feb. 27 the temperature rose to 103.2° F. (39.55° C.). White blood cells numbered 7,800 (neutrophil polymorphonuclears 5%, lymphocytes 82%, monocytes 13%). On Feb. 28 the temperature varied between 99.4° F. (37.4° C.) and 103.4° F. (39.7° C.). Blood count showed: Hb, 13.5 g. (81%); R.B.C., 4,190,000; W.B.C., 6,700 (neutrophil polymorphonuclears 0.5%, eosinophils 1.5%, normal lymphocytes 48%, large lymphocytes 10%, normal monocytes 35.5%, promonocytes 2.5%, blasts 0.5%, plasma cells 1.5%). There was some redness of the inner part of the left eyelid, extending for two inches (5 cm.) down the face. On March 1 the blood showed W.B.C. 5,400 (neutrophil polymorphonuclears 5%—1 segmenter and 4 stabs—eosinophils 1%, normal lymphocytes 48%, large monocytes 37%). The patient was sent to hospital, and treatment was started with intramuscular injections of 10 ml. of pentose nucleotide every 6 hours and 10,000 units of penicillin every 3 hours. Because of a possibly allergic reaction to one of the pentose nucleotide injections, this was changed to 5 ml. every 3 hours. These two drugs were continued for 48 hours and then stopped because they were no longer necessary. On the day of admission the temperature ranged between 99.4° F. (37.4° C.) and 101° F. (38.3° C.). Next day (March 2) the highest temperature was 100.6° F. (38.1° C.). There was no fever thereafter. On March 2 the white cells numbered 8,100 (with neutrophil polymorphonuclears 31%—2 segmenters and 29 stabs—eosinophils 3%, lymphocytes 40%, monocytes 26%). On March 3 the white cells had risen to 13,300, with neutrophil polymorphonuclears 55%—9 segmenters and 46 stabs—eosinophils 1%, lymphocytes 23%, and monocytes 21%. There was some soreness deep in the left throat on March 2, persisting for two days. It was not severe. Nothing was visible. No ulcerations were seen in the mouth or elsewhere. The redness of the eyelid and face began to subside promptly after penicillin was begun. On March 4 the white cell count was 17,000, with 56% neutrophil polymorphonuclears (22 segmenters, 27 stabs), eosinophils 2%, lymphocytes 26%, and monocytes 16%. On March 8 the patient felt well. The white count was 10,000, with 66% neutrophil polymorphonuclears (29 segmenters, 37 stabs), eosinophils 3%, lymphocytes 27%, and monocytes 4%. The patient remained in good condition after this.

Comment

The eosinophils were explained by the presence of bronchial asthma. It is usual to have leucocytosis after recovery from agranulocytosis. A high monocyte count, if it persists, is usually considered a favourable sign, though not necessarily so (Reznikoff, 1938). There is, however, disagreement about this (Jackson, 1943). The total white count was never very low in this case, and except for the fever there were few symptoms, indicating that this case was a mild one. Penicillin, preferably in larger dosage than used in this case, offers a logical approach to the low resistance against infection always present in agranulocytosis.

STORAGE OF PENICILLIN

The Ministry of Supply states that the penicillin now produced in the United Kingdom is usually of such potency and of such other characteristics that it can be stored satisfactorily for 12 months under cool dry conditions at a temperature not exceeding 15° C. (60° F.). A dry cellar is suitable for this purpose. If readily available, refrigerated storage should still be generally used. Anhydrous preparations, such as lozenges and ointments made with a greasy base, may be stored in a similar manner, and patients should be advised accordingly. Refrigerated storage is necessary for aqueous preparations such as creams. Patients should be advised to keep penicillin creams in a cool place, under which conditions they may be regarded as effective for one week. Solutions for injection should be used within 48 hours of preparation, and while awaiting use should be stored at a temperature not exceeding 4° C. (40° F.).

A NOTE ON EXTERNAL OTITIS

BY

G. A. JAMESON, M.B., B.S.

Wing Commander, R.A.F.V.R.

External otitis has received no little prominence in contemporary otological literature, largely by reason of the disability occasioned in the Services through this relatively trivial but often intractable complaint. Much of this literature has been devoted to external otitis in hot climates (Daggett, 1942; Gill, 1942; Senturia, 1944; Basil-Jones, 1945; Coghlan, 1945), where, probably owing to the prevalence of the desquamative type described by Daggett (1942) and Morley, the ever-present fungus spores preparing the soil for the growth of bacteria in the macerated surface epithelium as described by Gill (1942) and Senturia (1944) in America, and the intolerance of the eczematous subject to heat, the incidence has been high—according to Daggett (1942) 48% of all ear cases.

It may therefore be of interest, by contrast, to review the exact frequency of external otitis as seen in an E.M.S. hospital over a period of three years in a population of some 70,000 of the three Services in this country—a population that has little changed in total numbers, though, of course, there have been frequent changes in the units that make up the whole.

During the period under review 8,431 new E.N.T. out-patients have been seen, and of these 787 (9.3%) have attended for external otitis. A total of 2,382 E.N.T. cases of all sorts were admitted as in-patients—194 (8.1%) of these with a diagnosis of external otitis. Where there has been a coexistent C.S.O.M. the case has been indexed as such, and these figures relate only to an external otitis in a meatus with an intact tympanic membrane.

Of the in-patients, 97 R.A.F. cases averaged 16.37 days in hospital under treatment, and 85 Army cases 16.4 days, so that this figure can be taken as a fairly accurate estimate of the time required to clear up an external otitis with in-patient treatment as carried out in the E.N.T. department of the hospital. These figures compare unfavourably with those of Daggett (1942)—63% in 4 days; Burrell (1945)—2 to 14 days; Johnston (1944)—7 to 10 days, using zinc peroxide; and Senturia (1944)—1 to 7 days for acute ears treated by sulphonamide insufflation technique. Senturia, however, states that of 12 chronic eczematous ears 11 required over 7 days of treatment.

As this E.M.S. hospital provided the only E.N.T. facilities for Service personnel in the districts occupied by some 30,000 R.A.F. and 35,000 Army troops, practically all cases of external otitis from this Service population requiring in-patient treatment would be included in these figures, and a reasonably exact calculation can be made of the man-power loss occasioned by this complaint. In the R.A.F., 97 men lost 1,407 days while under treatment, and of the Army population 85 men lost 1,394 days—a total of 2,001 man-days lost in a three-year period. In other words, the two Services together were deprived of the services of rather less than 3 men out of a total of 65,000, or 0.0046% of their man-power.

No attempt has been made to index the cases according to their aetiology, but certain well-defined types are readily recognizable.

Types of Case

1. Cases associated with a seborrhoeic dermatitis of the scalp and very frequently a chronic blepharo-conjunctivitis. In this type, treatment of the scalp with sulphur and salicylic acid is essential to success.

2. The allergic eczematous type. In these cases the external otitis appears to be just such an allergic manifestation of a hypersensitive skin as eczematous lesions elsewhere. Phenobarbitone 1/2 gr. (7.5 g) twice daily, as a general sedative, can be given over a prolonged period, and concentrated vitamin A, 100,000 units daily, appears to be helpful in treatment.

3. Cases associated with a pyogenic infection, as in impetigo contagiosa. As the organism is usually a penicillin-sensitive streptococcus or staphylococcus a spreading impetigo responds rapidly to systemic penicillin.

4. Mycotic external otitis. By contrast with the experience of otologists in America (Gill, 1942; Senturia, 1944), mycotic

external otitis is exceedingly uncommon in our experience in this country.

Treatment

The secret of success with all types is regular aural cleansing of the meatus and in particular of the little well of pus that lies where the lower meatal wall dips downwards to meet the inferior margin of the drum. With much meatal oedema fairly tight packing with a gauze wick impregnated with glycerin and ichthylol 10% yields the most useful results, after a few days a 2% aqueous solution of gentian violet lightly applied to the meatal wall is as a rule effective. D'Alibour's paste with gentian violet is a useful application to an excoriated auricle. All other suggested medicaments have been used with varying success—2% phenol in calamine lotion, the sulphonamide powders and pastes, aluminium acetate, silver nitrate, argyrol, and pigmentum castellanum—but there is little to be said for frequent changes in treatment, which should be standardized, so far as is possible, in any E.N.T. department. Penicillin locally has seldom been of any value, as most cases will clear rapidly without resort to a treatment that still has certain practical disadvantages over other dressings, and those that do not clear up seem invariably to culture a profuse growth of penicillin-insensitive bacilli.

Occasionally, and perhaps particularly with the eczematous external otitis, small doses of x rays, repeated at weekly intervals, are helpful, though some care has to be exercised, as overdosage can lead to disastrous results.

Summary

The incidence of external otitis, together with the man-power loss occasioned thereby in 30,000 R.A.F. and 35,000 Army troops, is calculated.

Certain well-defined types are described.

The importance of regular visual aural dressing is stressed and standardization of treatment recommended.

Medical Memoranda

A Case of Tropical Eosinophilia
(Weingarten's Syndrome)

The following case is reported because of the difficulty of diagnosis in some cases of eosinophilia and the satisfactory response to treatment. Cases of Weingarten's syndrome—eosinophilia, with asthma and temporary changes in the x-ray appearance of the chest—have been reported from India and the Middle East, and doubtless will be increasingly recognized in cases from other tropical countries.

The patient, a European male aged 37, had spent 12 years in Nigeria, during that time his only illnesses were infective jaundice and M.T. malaria. Less than six months after his return to England he began to suffer from attacks of nocturnal asthma with paroxysmal cough; the attacks caused orthopnoea, but were not very severe or prolonged. There were no other symptoms apart from some anæmia. A skiagram of the chest about this time showed no abnormality.

An attack of malaria was the occasion for a blood count, which showed 12,400 white cells, of which 20% were polymorphs and 59% eosinophils; myelocytes were present. There was no evidence of blood or alimentary parasites or any symptoms of filariasis. No treatment was given, and the blood count improved somewhat during the following year. The patient complained of lassitude, and he had another attack of malaria as well as occasional asthma. About eighteen months after the first symptoms there was a febrile attack lasting several days, again with nocturnal asthma and widespread urticaria. A blood count showed 36,200 white cells, of which 10% were polymorphs and 74% eosinophils. Again no parasites were found.

A diagnosis of Weingarten's syndrome was made and three injections of N.A.B. were given at weekly intervals. The patient's health and blood count rapidly improved, and the latest examination showed 5,800 white cells, with 58% of polymorphs and 5% eosinophils.

Redhill Country Hospital, Surrey

E. A. HUNTER, M.R.C.P.

Simultaneous Extra- and Intra-uterine Pregnancy

This condition is still uncommon enough to warrant the recording of a case.

HISTORY OF CASE

An African (Basutu) female, aged about 30, was admitted to the Nigel Hospital on Nov. 29, 1945, complaining of severe intermittent pain in the hypogastrium and the right iliac fossa of a few days' duration. A history of approximately six weeks' amenorrhoea was given. The salient features of the examination were the presence of a very tender moderately mobile oval mass, the size of a hen's egg, just to the right of the midline, continuous with and extending laterally from the fundus uteri, and signs suggestive of early pregnancy. There was no vaginal bleeding. Ectopic pregnancy with threatening rupture was considered in the differential diagnosis and exploratory laparotomy was advised. Here, however, primitive tribal custom, later to have tragic consequences, intervened. No operation could be performed without the consent of the patient's father, and this was withheld. With conservative sedative treatment the pain and tenderness subsided within a week, and the patient was removed from the hospital by her husband.

On Jan. 1, 1946, at 12.30 p.m., the patient was readmitted in an extremely critical state. She was literally "bled white"; the pulse rate was 120, though the tension and volume felt deceptively good. The systolic blood pressure was 80 mm. Hg and the temperature 97° F. (36.1° C.). The abdomen was distended and tender, especially in the lower half. There was guarding but no rigidity. No masses were palpable. Cullen's sign was not detected. There was again no vaginal bleeding.

The history now given was that she had remained free of pain until five days previously, when intermittent lower abdominal pain had recommenced, increasing in severity up to the morning of re-admission. History-taking was difficult, as frequently is the case with Africans, and the presence of shoulder-tip pain was not elicited. A diagnosis of ruptured ectopic pregnancy was made, though the absence of vaginal bleeding was commented upon. Consent to operation was obtained, the father, who was present, recognizing at last the dire straits in which his daughter found herself.

Serum and 10% glucose in saline were administered in the ward and continued in the theatre until blood could be obtained from the nearest transfusion depot, when it was immediately given. Open ethyl chloride and ether anaesthesia, with oxygen, was employed. The abdominal cavity was found filled with blood and clots, the cause being a ruptured ectopic pregnancy on the right side. The interstitial portion of the right Fallopian tube was the site of a pregnancy of about three months' duration, and the adjacent fundus uteri and isthmus of the tube had also been involved. Only the omentum had become adherent to the sac and was freed with ease. There was no difficulty in removing the sac and its liberated contents. The uterus, however, was seen to be much larger than is usual in an ectopic pregnancy, and on deeper exploration of the eroded right half of the fundus uteri a second sac came into view. The opening was enlarged and by gentle traction an intact gestational sac was delivered, the foetus of the same size as that of the extra-uterine pregnancy. A partial removal of the fundus was quickly performed. At this stage the patient's condition deteriorated markedly, and despite all resuscitatory measures death ensued.

COMMENT

King (1943) has classified coexisting intra- and extra-uterine pregnancies into two types: (a) combined or simultaneous, and (b) compound. The combined type is probably the same as a multiple pregnancy except that one or more implantations are extrauterine, and the case above would therefore fall into this group. In the compound type the extrauterine pregnancy may have been present for a long time, usually symptomless and dormant. Superimposed on this an intrauterine pregnancy then occurs.

The fatal outcome was most unfortunate, as ruptured ectopic pregnancies usually respond well once the source of the haemorrhage is under control. To have delayed operation until the beneficial effects of the transfusion, etc., were more pronounced would have been dangerous, and is contrary to the generally held view that immediate operation, with supporting measures, is the procedure of choice (Ware and Winn, 1941). It is a sad thought that operation, when first advised, would probably have given a satisfactory result.

With regard to the pre-operative diagnosis of this combined condition, the absence of vaginal bleeding would appear to be a point worthy of future notice.

My thanks are due to Dr. Magnus G. Myers, the surgeon in charge of the case, for permission to publish this report.

MAX SEGAL, M.B., B.Ch., M.Sc.

Nigel Hospital, Dunnottar, Transvaal.

Reviews

FAMILY HEALTH AND HOUSING

A Home of Their Own. By K. E. Barlow. Preface by George Scott Williamson, M.D. (Pp. 96. 4s. 6d.) London: Faber and Faber. 1946.

Dr. Barlow's book is an excellently written treatise on the rehabilitation of the family, and it has a postscript which in effect is addressed to the Minister of Health urging upon him unusual, extra-departmental, out-of-regulation action in a good cause. Dr. Barlow practises in Coventry, where he and a number of citizens have been inspired by the example of the Pioneer Health Centre at Peckham—the grouping of a whole community round a family health club—and desire to reproduce it in their own devastated town. They desire to do more than this—to integrate the proposed centre with a part of the new housing. In Coventry about 20,000 houses need to be built, and it was felt that one of the new neighbourhoods within the city might be directly related, by the circumstance of householding, to the health community centre. The tenants of this satellite suburb would themselves plan their neighbourhood, with the health centre as its focus. Every one of them could thus be counted upon for at least a minimal participation in the activities of the family health club and the administrative life of the community. For the Peckham idea is not merely a centre, it is also a periphery, manifesting itself in the separate homes as well as in the club activities. It is more even than this; a healthy home requires a healthy environment, and therefore the idea reaches out to town planning and communal life in general. Accordingly Coventry families, mainly of the working class, who were later to be the tenants of the new houses, were recruited. A housing society was promoted for the planning of 2,000 houses, a site marked out, and a mortgage of two millions arranged at a reasonable rate of interest. The city authorities were persuaded of the excellence of the scheme, the good will and co-operation of experts were enlisted, an offer was even forthcoming of some of the housing of the ex-Service men's council. But, of course, questions of priorities arise. Control of housing standards is most effectively exercised by placing housing in the hands of local authorities, and no local authority can make the tenancy of its council houses conditional upon membership of a family health club, nor concede to a group the right to arrange its own housing. Will the Minister permit an experimental deviation from uniformity by delegating certain housing to a non-profit-making society which is able to establish the necessary conditions for social research into health?

In the main body of the book Dr. Barlow discusses courtship, marriage, child-bearing, and education, from the standpoint of a biologist, and indicates very cogently where society has so often gone wrong.

SULPHONAMIDE-RESISTANT GONORRHOEA

Les Gonococcies Sulfamido-Résistantes. By Claude Huriez, R. Dumont, G. Patoir, and J. Leborgne. (Pp. 61. 50 francs.) Paris: Masson et Cie. 1945.

This little book on sulphonamide-resistant gonorrhoea is written by Frenchmen obviously for Frenchmen, because penicillin is included only in an addendum though the book was published in 1945. After a brief introduction the authors deal successively with the history of the treatment of gonorrhoea, sulphonamide resistance in men and women, and the various methods of dealing with resistant cases. It is of interest to note that the resistance is attributed to adaptation of the gonococcus to the drug, and particularly to the fact that prostitutes often use it as a prophylactic, especially before an examination; no mention is made of the possibility that there are naturally resistant strains which have survived while the sensitive ones have been killed off. Many of the methods of treatment are well known, but others are less so, particularly the use of antigenococcal serum locally and of infiltration with a local anaesthetic for epididymitis.

The use of silver salts both for purposes of treatment and for their provocative effect still seems common in France, and British readers will cavil at the use of such expressions as "disinfecting the mucous membrane," particularly when

increasing strengths of potassium permanganate are recommended. Most of the references are to French and American literature, but the authors are somewhat at fault when they suggest that Mac Elligot (sic) was at St. Mary's Hospital in 1941 (actually he was in the Royal Air Force) and that Col. Harrison, who as our readers know was, and is, Adviser in V.D. at the Ministry of Health, was responsible for Army statistics.

This booklet is largely of historical interest, but is worth reading if only to see how French doctors faced their difficulties without the help of penicillin.

ARBUTHNOT LANE

Sir W. Arbuthnot Lane, Bart., C.B., M.S., F.R.C.S. *His Life and Work.* By W. E. Tanner, M.S., F.R.C.S. (Pp. 192, 15s.) London: Baillière, Tindall and Cox, 1946.

If a surgeon's greatness is judged by the threefold standards of originality of mind, manual skill, and power to inspire others, Lane is perhaps the greatest British surgeon of the past hundred years. Lister was an original thinker, but no operator. Macewen was a brilliant craftsman who made outstanding advances, but he never won affection and he left a desert behind him. Moynihan was a technical artist and a gifted orator, but he lacked that humility which great leaders possess. Lane illuminated every branch of surgery by his genius, he operated with a sure dexterity that has never been surpassed, and he had the ability to inspire deep devotion and blind loyalty in all who worked with him, even for short periods and in a humble capacity. Many of the leaders of surgery in this generation and the two before it have been proud to call themselves Lane's men.

Lane was a leader in transforming Listerian antiseptics into modern asepsis. He taught surgeons to change as well as to gown before operating. He was the first, in Britain at all events, to explore the mastoid antrum, to drain the lateral sinus and tie the jugular vein for septic thrombosis, to resect a rib for empyema, to repair cleft palate successfully, to establish a new standard in the treatment of fractures. He was the originator of modern views on skeletal mechanics, the teacher of the "no touch" technique, the designer of a host of instruments which have been modified but never improved upon. As orthopaedics passes from a dignified descendant of bone-setting to a major branch of surgery, Lane emerges as its founder and first high priest. Beside these lasting achievements his failures and his foibles pass into insignificance.

Those who knew Lane will find much of the man they loved and honoured in this book, but it is doubtful if strangers will do so. Tanner's real admiration for his old chief is apparent, but in a desire for completeness he has lost proportion in detail. On page 3, just when a picture of the central figure is emerging, he breaks off to mention Hoeffticke and Horniman, names that mean nothing to-day, and to quote at length Lane's views on liquid paraffin. Appreciations of his vivid and simple character are there: so also are long quotations from the laudatory speeches that greeted him in America and from the letters of his admirers in this country. His glories and his failings stand side by side in equal prominence.

THE MIND OF THE CHILD

The Psychoanalytic Study of the Child. Volume I. 1945. (Pp. 423, 30s.) London: Imago Publishing Co., Ltd.

This is the first annual volume of papers on the psychology of the child from the point of view of the strict psychoanalytic discipline. There is not a great deal of coherence in the sum total of the papers, so that each must be read on its own merits, but it is no doubt useful to have them collected in one volume.

The first section deals with so-called genetic problems—that is, the causal influences which promote neuroses and disturbed behaviour in general. Perhaps the most important of these is a criticism of Melanie Klein's theories by Dr. Glover, who disapproves of them inasmuch as they tend to destroy the coherence of the original Freudian doctrine. There is an interesting comparison between children brought up in a founding home and in a nursery. In the former protection is at a minimum and frustration at a maximum; in the latter the reverse is the case. Both extremes are held to be bad for the future emotional development of the child, over-protection being specially deleterious after the first year.

In the second section child analysis is discussed by Anna Freud in a paper on the indications for child analysis and in several clinical case records. Case records and commentaries illustrate the third part, which is given up to guidance work. The fourth part deals with education and the contributions of psychoanalysis to this end. These contributions are slowly building up a collection of observations which should eventually allow of a practical formulation of the goals of education and the methods which are most likely to be successful in achieving these goals. The fifth section considers problems of group life, the most important of which are the gangs of young delinquents, whose influence on the mind of the individual member must be understood if successful reclamation is to be achieved. Finally there are some reviews of books and commentaries, including one on the literature dealing with the evacuation of children in wartime.

This book will be useful only to those who understand the technical terms used by psychoanalysts and appreciate their full implications.

A BOOK ON REFRACTION

Refraction of the Eye. By Alfred Cowan, M.D. Second edition, thoroughly revised. (Pp. 278; 181 engravings and 3 coloured plates. 24s.) London: Henry Kimpton.

Refraction of the Eye, by Dr. Alfred Cowan of Philadelphia, covers a rather wider field than do books on the subject in this country. The purely clinical aspects of refraction work are discussed in the concluding third of the text, and the teaching does not differ materially from the current practice here, though simplification is carried to lengths where it becomes confusing. This is seen from the advice given in omitting the conventional symbols for sphere and cylinder in the prescription. None the less the text is remarkably complete and contains aspects not well known to the English reader. This applies less to the objective than to the subjective methods, which include accounts of cyclodamia (a modified form of fogging) and velonoscioscopy. Many practical points reveal the experienced refractionist and teacher. The concluding chapter on contact lenses and telescopic spectacles is lucid and brief.

The greater part of the book is taken up with a geometrical exposition of optics. The subject-matter is rather more advanced than is expected here of candidates for the diploma examinations. It is, however, well presented and adequately illustrated. The book contains a bibliography with about three hundred items (selected on no obvious principle).

Notes on Books

In *Brompton Hospital Reports*, vol. xiii, 1944, the physicians and surgeons of the hospital make their annual bow with a series of exceptionally interesting papers. Mr. J. E. H. Roberts inquires "What is the right time, please?" and discusses the best moment for operation in various tuberculous conditions. Dr. W. D. W. Brooks analyses nearly half a million mass radiography figures from the Navy and discusses the management of early cases. Dr. A. Margaret Macpherson reports on the subject of the supervision of the child in the tuberculous household. Dr. Clifford Hoyle describes with great charm the part which disease has played in the lives and works of great men. But these are only some of a series of interesting contributions. The volume concludes with a sub-committee's report from the hospital upon the incidence of tuberculosis among the nursing staff, together with recommendations for hygiene. Altogether a useful volume, obtainable, price 10s. post free, from the Secretary, Hospital for Consumption, Brompton, London, S.W.3.

Sir LIONEL WHITBY and Dr. C. J. C. BRITTON are to be congratulated on the appearance of a fifth edition of their textbook on *Disorders of the Blood* (J. and A. Churchill, 30s.) only ten years after the first edition. The success of their book is due to two things. The first is the personal experience of the authors and the shrewd judgment with which they have been able to marshal the literature of haematology. The second is the remarkably reasonable price. This edition contains some new plates, and recent work on the rhesus factor has been well summarized. Future editions will probably pay less attention to lysocleithin, as Fahræus's attractive theory of haemolysis has been generally abandoned for want of confirmation, and more attention to the value of penicillin in agranulocytosis. This book still contains all that anyone but a professional haematologist need know about the diseases of the blood.

Nova et Vetera

SIR MORELL MACKENZIE

Morell Mackenzie. *The Story of a Victorian Tragedy*. By R. Scott Stevenson. (Pp. 194. 13s.) London: William Heinemann Medical Books Ltd. 1946.

Almost sixty years have elapsed since the death of the Emperor Frederick III, from cancer of the larynx, after an illness which was then, and to a small extent still remains, a topic of discussion throughout the civilized world. Medicine and politics have often been strangely intermingled. The diseases of kings and emperors and dictators exercise an influence which extends far beyond the individual sufferer. So it was with the case of the Emperor Frederick: fatal to the patient to be sure, but fatal also to the reputation of the London physician who attended him.

Summoned to Berlin on May 18, 1887, to attend the Crown Prince, as he then was, Morell Mackenzie found the German doctors prepared to operate, having diagnosed the case as one of cancer of the larynx. It would be a formidable undertaking, but the final decision was to rest with Mackenzie, who had been chosen for this task by his German colleagues. Mackenzie wisely advised that first of all a portion of the growth be removed and submitted to Prof. Virchow for microscopical examination. The result was inconclusive. The doctors differed. The case became a subject for argument, not only in medical circles but even in drawing-rooms and salons throughout Europe. No operation was performed, save that of palliative tracheotomy, and eventually the Emperor died, on June 15, 1888, having reigned for only ninety-nine days. It was a tragic illness, tragic alike to the Emperor, to Sir Morell Mackenzie, who attended him throughout, and to the German nation, just about to shake off the regime of Bismarck and to adopt a Liberal policy under the guidance of a new ruler.

Such, in brief, is the theme so clearly and logically surveyed in this interesting work. The author, well known as a laryngologist and as a writer, possesses all the qualifications which his task demanded. He traces the career of Sir Morell Mackenzie, the "Father of British Laryngology," whose textbook is still in daily use and who founded the first hospital for diseases of the throat. He acknowledges that Mackenzie was indiscreet, vain, and polemical, but he denies that he was ever insincere. The hasty and ill-advised publication by Mackenzie of a popular work entitled *Frederick the Noble*, in which he attempted to vindicate his own conduct, only added fuel to the fire of controversy.

The author, championing the cause of the tragic laryngologist, concludes that Morell Mackenzie will be remembered "as the chivalrous physician who, single-handed and in the face of overwhelming opposition and intrigue, by his determined intervention prolonged the life and effected the accession of an Emperor." It is for each reader to make up his mind, ere he reaches the last page, whether such a conclusion is justified. Of supreme interest to every medical man, the book is sure to attract many non-medical readers who will have no difficulty in following the argument and the story, so graphically unfolded under such headings as "The Legend," "The Physician," "The Patient," and so on, throughout eight chapters. This fresh account of the career of Sir Morell Mackenzie, viewed in the light of half a century, ably expounded and well portrayed, is an interesting commentary on subsequent events, both medical and political, and as such it is certain to be widely read and as widely discussed. The bibliography relating to each chapter shows that the author has tapped every available source of information, and the illustrations are interesting and well chosen.

SIXTEENTH-CENTURY FRENCH DOCTORS

The Doctor in the French Literature of the Sixteenth Century. By Nancy F. Osborne. (Pp. 140. \$2.00 or 13s. 6d.) New York: King's Crown Press; London: Oxford University Press.

The extensive bibliography of this scholarly book deals with the "doctor" as seen by a satirist and some poets of the sixteenth century in France. It was not a good period. Medical science had fallen away from the times of Hippocrates and Galen, when rival schools of medical thought indulged in philosophic speculation and argument. Then rational medicine was backed up by observation of facts and experimentation,

which gave an impetus to various works in anatomy, physiology, and cognate subjects. When Greek medicine reached Europe it was enthusiastically received until the end of the fifteenth century, when it gradually fell from the peak of Greek and Arabic doctrines into the morass of astrology, magic, and alchemy.

It had been the custom of the Arabs to absorb the culture of nations whom they conquered. The medical discoveries of the Greeks interested them greatly. It was not until Ambroise Paré (1517-90), the father of surgery, with his work on the control of haemorrhage, that the first effective steps in surgery came forward. Leonardo Da Vinci was the first to dissect human bodies; he illustrated his findings in accurate drawings. Syphilis raged during the sixteenth century. Neglect of the simplest rules of health disseminated disease and death throughout France. The profession was in bondage to the belief in the divine origin of sickness and in the prevention of healing of diseases by supernatural powers. After sketching the background of this period the author goes on to deal with the physicians and their helpers—the apothecaries. We laugh at the charlatans, puffed up with Falstaffian egotism and bombast, and look with compassion on their patients. The general review of the sixteenth century shows it to have been a time of medical chicanery and fraud, which was followed by the European Renaissance that gave birth to modern medical science.

ANGELO MOSSO, 1846-1910

One of the founders of the experimental physiology of man, Angelo Mosso, the centenary of whose birth occurred on May 30, received his physiological training from such giants as Schiff, Ludwig, and Claude Bernard. His short life, crowded with achievements and honours, was lived in Turin, where he graduated M.D. in 1870 and eight years later succeeded Moleschott as professor of physiology. While his name is eponymously linked with the ergograph (1898) and the Istituto Angelo Mosso, he was a versatile and tireless worker, possessed of remarkable technical skill, in such fields as fatigue, sleep, movements of the intestine, temperature of the brain, and respiration at high altitudes. Failing to appreciate Paul Bert's correct hypothesis that mountain-sickness is 'due to actual want of sufficient oxygen in the air inspired into the lungs, he advanced his acapna theory of 1897, which was to hold up progress for 20 years.

Founder of the *Archives Italiennes de Biologie* (1883), president of the International Physiological Congress (1901), Rector Magnificus of his Alma Mater, and Senator, Mosso devoted his scant leisure to promoting public hygiene and popular health education, and to founding football clubs, mainly on English lines. He died on Nov. 24, 1910, of diabetes, an illness which he had borne philosophically for many years.

EARLY MEDICAL MSS. AND BOOKS AT EDINBURGH UNIVERSITY

A selection of books and manuscripts, to illustrate the current series of lectures on the history of medicine, has been placed on view in the Upper Library Hall of Edinburgh University. Included among manuscripts of the thirteenth century are beautifully written copies of the *Breviarium Medicum* of Serapion, a Syrian physician of the ninth century, and of Avicenna's *Canon of Medicine*, a favourite textbook, by the "Prince of Arabian Physicians," which retained its popularity for many centuries and is said to be still used by native practitioners in India. Of slightly later date is a fifteenth century manuscript of the *Regimen of Health of Salerno*, the best-known work of that famous School of Medicine. It contains a full-page illustration of a mediaeval physician and one of his patients.

A modern manuscript of much interest, on loan from the Royal College of Surgeons, is a volume of notes of lectures on surgery, delivered by Lister while he was professor in Glasgow, containing the first written account of his "antiseptic principle."

Among the printed books the greatest rarity is *Christianismi Restitutio*, published in 1553 by Michael Servetus, who suffered death by burning at the hands of Calvin. Although it is a theological work, it contains an account of the pulmonary circulation. Only two other copies of the book are known to exist. There are also on view first editions of *De Re Medicina* by Celsus, dated 1478; of Vesalius's *Fabrica*, 1543; of Harvey's *De Motu Cordis*, 1628 (from the library of Alexander Monro tertius); of Willis's *Cerebri Anatome*, with illustrations by Sir Christopher Wren; of Jenner's *Inquiry into the Causes, etc., of Cowpox*, 1798; and of W. T. G. Morton's pamphlet on the use of ether as an anaesthetic, 1847. One of the cases contains an interesting collection of illustrated "Herbals" and a catalogue, dated 1683, of the Edinburgh Physic Garden, which occupied part of the present site of Waverley Station.

The exhibition is to remain open, during library hours, until the end of June.

THE MECHANISM OF AIR-BORNE INFECTION

What is the nature of the particles inhaled when infection is air-borne? There have been three periods of belief on this subject. Fifty years ago the vehicle exclusively considered appears to have been dust, but at the end of the last century Flügge introduced the conception of droplet infection. When Wells in 1935 showed that fluid particles either fell to the ground or evaporated, according to whether they were large or small, the droplet nucleus replaced the droplet as the supposed vehicle of aerial transmission. The finer particles of secretion expelled from the mouth and nose were supposed to dry in the atmosphere, being thus converted into minute particles of solid mucus, which floated in the air and in which bacteria survived. That many did in fact remain in suspension, and that even the more delicate respiratory pathogens could survive in this form for at least two days, Wells was able to show experimentally. This was the third phase of belief. It now appears that we may be entering upon a fourth, which is really nothing more or less than a reversion to the nineteenth-century doctrine that the vehicle of air-borne infection is dust. Studies made during the war of the mechanism of cross-infection in surgical wards have incriminated dust to an astonishing degree: the ease with which haemolytic streptococci can be recovered from the dust of septic wards, and the formidable rise in their numbers in the atmosphere itself consequent on floor-sweeping and bed-making, have been repeatedly demonstrated. The source in these circumstances may be the soiled dressing of a septic wound. How far are these findings applicable to infection exclusively derived from the upper air-passages?

A decided answer to this question is given in the paper by Ronald Hare and Dorothy M. Mackenzie on page 865. They take the extreme view that the dangers of direct air-borne infection are comparatively slight, and that the contamination of clothing and other fabrics, with subsequent liberation from them of infected particles, is the usual mechanism of respiratory tract infection. In support of this thesis they advance evidence which is in part experimental and in part circumstantial. Their experimental studies consisted in collecting bacteria expelled from the mouth and nose in such a way as to estimate their number and distribution in space. By arranging a series of culture plates in an arc facing the experimental subject, giving positions ranging from level with the mouth to vertically below it, and by counting colonies in the cultures so obtained, they determined the direction taken by particles of expelled secretion. Two features are noteworthy in the

results so obtained. One is the overwhelming importance of the sneeze in scattering possibly infected secretion: it produced thousands of colonies, while other forms of movement furnished total colony counts of the order of one hundred or less. The second point is the pronounced downward path taken by expelled particles, even at the short range of 1 ft. (30 cm.) used in most of these experiments. The highest colony counts after coughing and sneezing were in plates in the half-way position, at an angle of 45° with the mouth; only blowing gave the highest count in the next plate above this, and the majority of bacteria expelled by talking fell almost vertically. The proportion in the horizontally situated plates was exceedingly small, except in those obtained by the unusual and perhaps practically unimportant act of blowing. Another type of experiment designed to ascertain how much secretion remains in the atmosphere at least for a time instead of falling immediately was the exposure of plates in a closed box, through an aperture in which the subject had talked, coughed, or sneezed five minutes previously. From these results it again appears that the sneeze is of outstanding significance; how they should be interpreted in relation to the authors' main argument is not altogether clear. The practical reality of Wells's droplet nucleus and the extent of its natural formation are vital questions which deserve still further study.

Other experiments were made to determine how many actually pathogenic organisms are expelled by talking and coughing, and it was found that the output of haemolytic streptococci by throat carriers demonstrable by the same methods is exceedingly small. This observation, which has been confirmed by others, is doubtless due to the localization of this infection in an area where particles are presumably not formed; it involves neither the larynx, the source of cough droplets, nor the tongue and lips, which form them in talking. But in some infections, notably those due to viruses, the infection of secretions is believed to be more widespread; hence the experiments with an indicator organism described in this paper. Those performed with plates at different angles to the mouth gave substantially the same results as before; the more interesting are those in which the organism was recovered from the subjects' clothing and pieces of fabric attached to it after instillation of culture into the mouth and nose, together with irritants to induce a condition resembling a cold. The recovery of the organism was highly erratic: it should not, for instance, be concluded, as some of the figures suggest, that the right and left lapels of the coat are selectively contaminated from the nose and mouth respectively. Nevertheless it seems to have been shown clearly that clothing is readily contaminated, and releases the infection on shaking when the secretion has dried; and, secondly, that the nose is the more prolific source of this contamination.

The circumstantial evidence that dust from contaminated fabrics plays a major part in the spread of respiratory infections is ingeniously assembled and of two principal kinds. First is the well-attested importance of dormitory infection, as distinct from most forms of exposure during the day. Here the infected fabrics are chiefly bed-clothes, and the commotion of morning rising causes a "sudden

release of the concentrated output of the night." There are then a series of episodes in which apparently unaffected persons have conveyed infection to another community, the inference being that their belongings and not their mucous membranes were at fault. It should perhaps be pointed out that these people may have been carriers in the ordinary sense; such evidence, apart from the striking instance of Shackleton's bale of blankets, is no more than suggestive. Nevertheless this paper presents an impressive bulk of evidence for revising our views about the mechanism of air-borne infection. We may not go so far as the authors in minimizing the danger of direct aerial spread, but we must recognize that the effects they have demonstrated are of great importance—notably the rapid rate of fall of the greater part of the secretion ejected from the mouth and nose. An interesting point is the distinction made between bacterial infections, in which infected particles are few and special conditions are therefore necessary for ready spread, and virus infections, whose transmission is relatively easy owing to the greater concentration of the virus in secretions. The authors point out that these matters must be taken into account in any attempts to arrest air-borne infection by means of ultra-violet light or germicidal mists and vapours. In view of the likelihood that such attempts will be a prominent feature of progress in hygiene during the coming years, any addition to our knowledge of how infection is transmitted is valuable. If the conclusions of Hare and Mackenzie are not fully accepted they should be a challenge to others to produce further proof that direct aerial transmission has at least some of the importance which has so long been attached to it.

ARTIFICIAL SUNLIGHT TREATMENT IN INDUSTRY

Artificial sunlight treatment has been hailed as a valuable tonic for industrial and office workers. It is claimed that this treatment lessens the incidence of sickness and accidents, reduces absenteeism, hastens recovery from illness and injury, and increases production. Such claims have encouraged managers in commerce and industry to install solaria for the benefit of their workers. Nevertheless, the more critical members of the medical profession who are able to advise industry have asked for more convincing evidence than that to be found in the published results of previous trials of the effects of collective irradiation of industrial workers and Service personnel.

A large-scale and controlled inquiry, the results of which have now been published, was planned and carried out by Dr. Dora Colebrook¹ under the guidance of a special committee of the Industrial Health Research Board of the Medical Research Council. The object was "to ascertain in a scientifically controlled experiment whether the collective irradiation of workers by ultra-violet light from quartz mercury arc lamps, using a minimum perceptible erythema dose, will reduce their rates of sickness absence and the duration of their colds." The technique of col-

lective irradiation adopted was one that has been advocated by medical and other observers for use in industry. Trials were made in three separate communities—viz., the clerical staff of various departments in the Admiralty, workers in a large factory making tanks and lorries, and those working above and below ground in a Yorkshire colliery. In all over 3,000 volunteers took part in the trials. In each of these three communities volunteers were allocated at random to one of four groups. The first received the full range of ultra-violet rays. The second and third groups were irradiated with lamps which had been fitted with screens to cut off the shorter ultra-violet rays—i.e., those with a wave-length of less than 3,300 A.U.—which are claimed to be responsible for the tonic effects. Each individual in the second group was given a weekly dose of vitamin D as 3,500 international units of calciferol, and those in the first and third groups were given an inert oil as a control. Thus, if there had been any evidence of vitamin D deficiency in the communities treated it would have been possible to decide whether the rays of the un-screened lamps were able to compensate for this. (It is known from previous work by Rosenheim and Webster² that the shorter ultra-violet rays falling in sufficient amount on the naked skin can prevent and cure rickets by converting ergosterol into vitamin D.) The fourth group received no treatment at all. The first three groups shared any possible psychological advantage in having "light treatment," in visiting the clinic, and in the resultant rest pause from work which the office and factory workers enjoyed. Such advantage, if any, might be illustrated by differences in sickness incidence and absenteeism between those who attended the clinic and those who received no treatment at all.

The results of these extensive and carefully controlled trials do not confirm the claim that the commonly accepted technique for the irradiation of factory, mine, and office workers with artificial sunlight is effective in reducing sickness and accident incidence and increasing efficiency. Those chosen for the trials had every opportunity of benefiting from the treatment, because half the clerical workers, many of the factory workers, and all the underground workers at the colliery spent the whole of their working time in artificial light. In none of these communities was the average amount of sickness absence found to be significantly less among those who had ultra-violet light treatment than among those who were exposed only to the screened lamps. In the two communities in which the duration of colds was studied, and in the colliery where injury and total absence were measured, the three treated groups did not differ significantly. Nor did any of the communities show any evidence, in the characteristics measured, of a vitamin D deficiency. A third of the people treated stated that their health had been better during their attendance for treatment, but there was no evidence that this benefit was due to the shorter rays, since the numbers were almost equally distributed in the treated groups. The treated groups in the colliery—i.e., those receiving and those not receiving the shorter ultra-violet rays—had a significant advantage over the untreated controls in respect

¹ Industr. Hlth. Res. Bd. Report No. 89. H.M. Stationery Office. (1s.)

² *Lancet*, 1925, 1, 1025.

of sickness, and total absence, but it was not possible to select at random the untreated group whose health in the previous year, when there was no sunlight treatment, was found to be less good than that of the treated men. In the office and factory those given no treatment at all showed fewer days with colds than those who were treated. This result probably has no significance, but was due to a greater accuracy in the records of those who attended the clinics.

The results of this investigation "debunk" some of the claims made by manufacturers and doctors for using a particular type of artificial sunlight as a tonic to prevent absence from work, but they provide no evidence as to the value of ultra-violet light for treating particular diseases, other than perhaps the common cold. A negative result such as this may be less satisfactory to the research worker than a positive one, but this inquiry will have been fully justified if it serves to illustrate both the method of and the difficulties inherent in carrying out such a carefully controlled and large-scale trial in an industrial population. Finally, it is hoped that it may succeed in diverting the attention of management and workers from what could at best be hardly more than a placebo to the more radical methods of preventing sickness and absenteeism in industry.

A STUDY IN MENTAL DEFICIENCY

In 1938 Penrose¹ published the results of a detailed clinical and genetic study of 1,280 cases of mental defect. Many important conclusions emerged, and it is to be hoped that the author may perhaps subject his material to yet further study, for it should remain a valuable storehouse of information for years to come. The excellent plan was adopted of publishing much of the original data *in extenso*, so that others with hypotheses to test can also benefit from Penrose's careful work. A similar study in the United States by Halperin² follows closely the lines of the parent work, Penrose's personal assistance being warmly acknowledged. Halperin's paper should, therefore, be considered in the light of the original work at Colchester, the main conclusions of which it strongly substantiates; in some directions further information has been obtained.

Halperin's sample consisted of 338 institutional mental defectives, thorough family and social investigations being carried out. As in Penrose's work, it was found that more mothers than fathers were mentally defective, which is probably due to the fact that the mentally defective woman more easily secures a husband than the mentally defective man secures a wife. Once again a clear distinction emerges between high- and low-grade mental defect. Idiots tend to have parents of normal mentality and to come from homes which are at least average. The feeble-minded have many similarly affected relatives and tend to come from inferior homes. Imbeciles are intermediate in these respects, but lie closer to the idiots. The suggestion is strong that low-grade deficiency is due to such influences as recessive genes, major accidents of development, and the like, whereas high-grade deficiency is to be attributed to intermediate inheritance involving many genes, aided by unfavourable environment. The interaction between poor heredity and poor environment may well set up a vicious circle and so be responsible for the

"social problem group" of the Wood report. A striking finding is the relatively high proportion of cases showing rare inherited defects, not always, or indeed usually, associated with mental deficiency. These include Friedreich's ataxia, deaf-mutism, anhidrotic ectodermal dysplasia, pseudo-hypertrophic muscular dystrophy, Hirschsprung's disease, and certain eye conditions. The presence of an abnormal gene may well make the whole process of early development precarious, so that in some instances the central nervous system suffers, leading to frank mental deficiency.

Halperin finds a notable association between intelligence of parents and their fertility. The number of registered births falls steadily from the 5.03 of defective x defective to 1.27 in above-average x above-average. It is remarkable, therefore, that Halperin should say: "... it is doubtful, however, if much significance can be placed upon this fact," and again, in his summary, "... but such differentials are not regarded as significant." His justification is another assertion: "It is difficult to foresee, under such circumstances, any tragic consequences in the distribution of genes for intelligence for years to come." This is followed by the one concrete suggestion: "Moreover, the fact that people of lower mentality generally come from the less favourable socio-economic status in society would suggest that perhaps some of the differences in intelligence test scores may yet be attributable to differences in environment as yet unrecognized." In this particular matter many readers will probably be considerably more impressed by Halperin's facts than by his opinions.

A test devised by Penrose is used to determine whether sex-linked genes may contribute to the determination of intelligence. The result is negative. The similarity in intelligence between husbands and wives among the parents is pronounced; it is one of the highest associations yet reported. It is pointed out that this must greatly increase the scatter of intelligence in the population. A large increase in the tendency for like to marry like would therefore much increase the incidence of mental deficiency. This may be one of the causes of the suspected increase of recent years.

CALCIFIED PULMONARY NODULES AND FUNGUS INFECTION

In an investigation for tuberculosis in student nurses in the U.S.A. Palmer¹ found a relatively high incidence of calcified pulmonary nodules, but the majority of the nurses with these lesions did not react to the tuberculin skin test. The diagnostic value of the test is not questioned, and therefore some other cause of the pulmonary lesions must be sought, such as a fungous disease. *Coccidioidomycosis* causes pulmonary lesions which may eventually become calcified.

It seems significant that the majority of the tuberculin-negative cases of pulmonary calcification were found in certain areas in the central-eastern States, which, however, do not contain any endemic focus of *Coccidioides immitis* infection but correspond to the region in which the greater number of cases of histoplasmosis have been found. In view of this observation the histoplasmin skin test was applied on a large scale to residents in this region, with the result that a high incidence of histoplasmin-positive reactors was found in certain districts and a relatively low incidence in others—for example, in Kansas City, Mo., there were 397 positive reactors and 28 doubtful reactors among 647 persons examined (61.5% positive), while in

¹ Med. Res. Cncl. Sp. Rep. Ser. No. 229, 1938, London.
² *Amer. J. ment. Deficiency*, 1945, 40, 8.

¹ *Publ. Hlth. Rep. Wash.*, 1945, 60, 513.

Minneapolis only 46 out of 971 persons examined gave positive reactions (4.7%). Palmer points out that the peculiar geographical distribution of the reactors is strongly suggestive of a specific cause of some kind, and if the reaction is significant of previous histoplasmosis it would imply a widespread distribution of the disease in a mild or subclinical form in the central-eastern States. Christie and Peterson² confirmed the findings of Palmer and furnished further evidence in support of the thesis that calcified nodules in the lungs of tuberculin-negative subjects, especially young children, living on the Appalachian plateau and the adjacent part of the Mississippi basin may be associated with undiagnosed *Histoplasma* infection. They gave instances of the close association between the histoplasmin reaction and residence in particular areas, and they described the case of an infant aged 10 months in whose lungs, at necropsy, early nodules were found and *Histoplasma capsulatum* was isolated from a hilar lymph node, although the child was not known to have suffered from histoplasmosis and had not died of that disease.

There is apparently nothing characteristic in the x-ray picture of the pulmonary nodules in histoplasmin-positive, tuberculin-negative cases, but the nodules tend to be multiple and are often bilateral; in contrast to the single nodules usually associated with the tuberculin-positive, histoplasmin-negative cases. Referring to the relatively high incidence of calcified lung nodules and histoplasmin sensitivity in young children, Christie and Peterson remark that "the age at which histoplasmin sensitivity develops and the age at which calcification appears are in such relationship that they might be cause and effect, while the age at which tuberculin sensitivity appears lags far behind the deposition of calcium."

Up to the present stage of the investigation the presumption of a clinically mild and unrecognized form of histoplasmosis is based entirely on the histoplasmin reaction, but the specific value of this reaction has yet to be determined. To this end, Emmons, Olson, and Eldridge³ conducted direct and cross sensitivity tests with histoplasmin, blastomycin, coccidioidin, and haplosporangin on artificially infected animals and on human patients, and the results of these tests showed an intimate allergenic relationship between histoplasmin and blastomycin, so that, under the conditions of the test, neither reaction could be considered specific. Blastomycosis (Gilchrist's disease) is found in the greater part of the Mississippi valley, and this disease, and perhaps other mycoses, should be considered alternatively to histoplasmosis as a possible cause of pulmonary calcification in persons who are histoplasmin-positive and tuberculin-negative.

The development of mass miniature radiography provides an opportunity to conduct a similar kind of investigation in England which would serve as a control to the American investigation.

"TROPICAL" EOSINOPHILIA

The condition known generally as tropical eosinophilia has for many years been recognized as a clinical entity, especially occurring along the western sea-coast of India; but its exact pathological basis has only lately been determined. A recent paper on eosinophilic lung by P. J. Hodes and F. C. Wood⁴ forms a further useful contribution to the literature on the subject. The association of lung symptoms with x-ray findings of a peculiar type and eosinophilia was at first recognized in 1939, and since then many other reports have been made. The aetiology is

obscure. Climatic and geographical factors would appear to play a part, and most patients live in areas near the sea. The occurrence of bronchospasm and eosinophilia has naturally led to a search for allergens, but so far no sensitizing factor has been identified. Carter, Wedd, and D'Abrera⁵ found several strains of the *Tyroglyphus* (cheese-mite) group in the sputum of patients with eosinophilic lung, but their observations have not yet been confirmed by others. The mites are, so far as is known, non-parasitic types such as normally are found in stored products, debris, etc. On the other hand, disease of the lungs due to parasites is known to occur in certain animals, including monkeys; and the possibility of similar infestation in man cannot by any means be ruled out. Coccidioidomycosis is known to be associated with lung symptoms and eosinophilia, but no mycelium has been found in association with tropical lung.

The signs and symptoms of the disease are variable. In most cases an initial fever is followed by a dry cough which gradually becomes more severe. Often the clinical picture becomes that of a patient with asthmatic bronchitis, and the symptoms tend to be worse at night and to respond to adrenaline. If untreated, the fever subsides in a few weeks, but the lung symptoms may persist and become chronic. In some cases, however, both fever and pulmonary symptoms may be entirely absent, and the condition is one of vague ill-health until examination of the blood establishes the diagnosis.

Eosinophilia occurs in all cases. The total white count is usually over 20,000 per c.mm. and can be much higher, and the percentage of eosinophils commonly in the region of 90. There is no gross change in the red cell count. The spleen is usually palpable. In febrile patients with pulmonary symptoms x-ray changes are the rule. Films usually show discrete lesions 2 to 5 mm. in size situated especially round the lung roots and bases. Even in untreated cases this x-ray picture tends to vanish spontaneously. But the x-ray appearances of the lung may be normal throughout in cases in which a firm diagnosis of tropical eosinophilia can be made by the blood count and the response to treatment. Neoarsphenamine or its allied compounds appears to be remarkably successful, and some four to six injections usually suffice to effect a cure. The specific nature of arsenical therapy was accidentally discovered during the treatment of a patient suffering from the dual complaints of syphilis and tropical eosinophilia.

Loeffler's syndrome presents many similarities to the condition described above, but there is doubt whether they both are the same or different diseases. Loeffler's syndrome differs in that it occurs in dry and temperate climates and tends to be mild and transient and to recover rapidly and spontaneously; on the other hand, eosinophilia and x-ray changes in the lungs are common. Until the aetiology of the two conditions has been worked out their relationship to one another must remain undecided.

Europeans returning from India may, it should be remembered, be suffering from tropical eosinophilia. A high eosinophilia in the absence of intestinal parasites or other obvious cause would seem to justify treatment with arsenic.

The Lloyd Roberts Lecture, 1946, under the auspices of the Royal Society of Medicine, will be delivered at 1, Wimpole Street, W., on Monday, Oct. 28, at 3 p.m., by Field-Marshal Viscount Montgomery of Alamein, the subject being "Morale: with Particular Reference to the British Soldier." Admission will be by ticket only, which will not be issued until early October.

DEVASTATED MEDICAL LIBRARIES

The Minister of Health attended at the Royal Society of Medicine on May 17 to give his blessing to a project for sending microfilm reproductions of medical literature published during the war years, of sufficient continuity to be instructive in the subjects with which they deal, to replenish the devastated medical libraries of Europe. Mr. Bevan spoke appreciatively of the natural apprehensions of publishers in this connexion, but he thought it would be easy to obtain assurances from the recipients of the microfilms that they would not be used for piratical purposes in the countries concerned. Medical learning in these countries, he said, was suffering not only from the loss of libraries representing the accumulations of the past, but also from the fact that for six years it had been impossible to keep abreast of medical publications elsewhere, and he thought the project must appeal to every civilized intelligence.

Dr. N. M. Goodman, medical director of U.N.R.R.A., said that in his contacts with medical men on the Continent during the last twelve months, when he asked them what was their greatest need, their almost invariable reply was "To be brought up to date." These doctors had been cut off from Western medicine, and many of their libraries had been destroyed. He remarked to the director of the university dermatological clinic in Warsaw: "At least you have got your records and textbooks," and the reply was: "Yes, but I had to take seven trips through the German lines to preserve them." In country after country there had been most serious deprivation. Medical schools complained that their libraries were not up-to-date, no books or periodicals having been received since 1939. Educational rehabilitation was not within the province of U.N.R.R.A. All it could do in this direction was to supply what he called "*ad hoc* literature"—directions, for example, on the use of penicillin or D.D.T. or whatever was supplied. Some 21 journals were needed, two-thirds of them American and one-third British, but there was no possibility of filling the British quota owing to shortage here, and it was obviously undesirable that the vacuum should be made up solely by the publications of one country.

A number of representatives of other countries then spoke briefly. The Yugoslav Ambassador, M. Leontitch, declared that in the University of Belgrade "not one book remains." Count Reventlow, the Danish Minister, said that his country had not suffered nearly as much as others, but it welcomed the opportunity of renewed contact with British and American culture. The Polish Chargé d'Affaires, M. Winiewicz, described the great destruction in Warsaw, where, before the war, the medical libraries contained half a million volumes. One of them, in the Ministry of Health, was now being reassembled, book by book, from second-hand shops. The First Secretary of the Netherlands Embassy said that not only had the libraries of Holland suffered from bombing and fire, but many doctors who had had to go into hiding had been deprived by a spiteful enemy of their library as well as of their other possessions. Prof. Soloviev, head of the Soviet Red Cross in London, representing the U.S.S.R. Embassy, and a representative of the Czechoslovak Embassy spoke in similar terms. A representative of the French Embassy said that in France the medical libraries, with one exception, had escaped major destruction in the war, and France would be quite ready to do what it could to fill gaps in other countries. Dr. Lynne A. Fullerton, representing the United States Embassy, was sure that the remarks of the Minister of Health, which he would transmit to the Surgeon-General, would be received sympathetically in America.

Sir Stanley Unwin said on behalf of his fellow publishers that there was not the slightest need for any personal appeal to them to do what was necessary. On the other hand, the question of copyright did arise, and the matter must be done in proper form. He was uncertain of the attitude of the Royal Society of Medicine on this question of copyright, but obviously the Publishers Association could not give away the property of its members to anyone; it was not theirs to give. If properly approached he was sure that those concerned would take the same attitude as they had done when approached by societies representing the blind, in which case permission was at once

given. He reminded the meeting that literary property was just the same as any other property, and permission was required for its use. The hon. librarian of the Royal Society of Medicine gave the assurance that everything required would be done to secure the necessary permissions before microfilming took place, and the meeting closed with expressions of general approval of the scheme.

HEALTH SERVICE FORESHADOWED IN NORTHERN IRELAND

The Minister of Health of Northern Ireland (Mr. William Grant) has announced that the Government will accept financial responsibility for providing a site for a new hospital to serve Londonderry and the north-west area. The Parliamentary Select Committee on Health Services recommended extension and improvement of the hospital arrangements in the north-west, and the question has been discussed with representatives of the few hospitals and local authorities concerned. The advice tendered to the Ministry is that the hospital needs of Londonderry and the north-west are urgent and can best be met by setting up a new provincial hospital of between 400 and 500 beds on the outskirts of Londonderry. It is considered that no further building work should be undertaken at the city and county hospital in the town and also that the Waterside Hospital should not continue indefinitely as a general hospital. The most immediate need is for maternity accommodation, and as soon as the site of the new hospital is chosen and the general plan agreed, work will be started on a maternity wing or block.

The scheme will eventually form part of the framework of the Government's plan for a comprehensive health service for Northern Ireland. The Minister, in a speech at Londonderry, stated that the time was approaching when there would necessarily be a substantial alteration in the scope, and perhaps the administration, of health services. He could give no indication of the Government's policy in the matter, but the Government was, of course, examining the proposals for England and Wales, and was determined that Northern Ireland should have a suitable health service no less efficient than the corresponding service in Great Britain. He could not say what authority or authorities would in future be responsible for the provision and administration of the hospital service, but in the meantime the Government would take financial responsibility for initiating this development at Londonderry. He made it clear that this assistance was not necessarily the only help which the Government would give towards meeting the cost of the new hospital. That cost would fall to be met under the general arrangements for the National Health Service when these were formulated. The most urgent need in Northern Ireland to-day was housing, and it would be some years before the hospital could be completed, but it would be so planned that the maternity section could proceed without delay.

The north-west of Ireland is poorly supplied with hospitals. The city and county hospital, Londonderry, has about 100 beds, the Tyrone county hospital, Omagh, is of about the same size, and there are district hospitals at Limavady and Strabane and a cottage hospital at Coleraine.

MATERNITY PROVISION IN N.E. ENGLAND

The fourth annual report of the North-Eastern Regional Hospitals Advisory Council, which promotes surveys of hospital facilities and ancillary needs in the counties of Northumberland and Durham and part of the North Riding, contains a memorandum on maternity service provision in this region.

The standard of institutional maternity provision suggested by the Ministry of Health is understood to be 50% of births, but there is a general feeling that the standard is too low, and that the desirable provision is more nearly 70%. But even by the lower standard, and reckoning one bed to serve 20 births in a year, six of the eight county boroughs in the region have too few beds, another—Tynemouth—has a small surplus, and Newcastle has a surplus of 170 beds, but many of these are temporary, cannot be kept open indefinitely, and may be closed quite soon. County Durham shows

the most marked deficiency; the county council is said to be keenly alive to the gravity of the problem and the need for the immediate provision of additional maternity accommodation. The position in the North Riding is also disquieting, but the county council is understood to have a scheme for the provision of a new maternity hospital of 80 beds, and the local authority at Middlesbrough is also desirous of increasing its provision from 50 to 150 beds.

The facilities for training midwives in this region are also generally regarded as inadequate. Part I training is provided at a number of hospitals, but the quality of the entrants is poor, and greater encouragement needs to be given to local authorities and hospitals generally to give Part I training. The more serious deficiency, however, is in Part II training. The only Part II training now given is in Newcastle, Sunderland, and Darlington, and by the Northumberland County Nursing Association. It is remarked that the Central Midwives Board appears to discourage the same hospital giving both parts of the training. There is a strong feeling that local authorities already giving Part I training should also be encouraged to give Part II.

An interim report by the Newcastle Hospital Centre Joint Committee on the allocation of a hospital centre on eight acres of land lying north-west of the Royal Victoria Infirmary, Newcastle; a report on the five-year programme of the Health Committee of the city and county of Newcastle, including a scheme for the development of Newcastle General Hospital; and a memorandum by the county medical officer of Northumberland on general hospital accommodation in the county are appended to this document.

FIRST AID ON THE HIGHWAY

The Standing International Commission on Highway First Aid has held its first meeting since the war. It was convened at the headquarters of the League of Red Cross Societies in Geneva under the chairmanship of its founder, Dr. P. Behague, vice-chairman of the French National Union of Touring Associations. This commission was established fifteen years ago and is composed of representatives of the major international touring and automobile organizations, the League of Red Cross Societies, the International Red Cross Committee, and certain national Red Cross Societies. Before World War II it fostered the establishment of first-aid posts on highways and issued rules for their organization. In addition to Dr. Behague and M. de Rouge, Secretary-General of the League, the following persons attended the meeting: M. E. Dronsart, Director-General of the Belgian Red Cross; M. P. Duchaine, Secretary-General of the International Touring Alliance, President of the Belgian Touring Club; Dr. E. Mende, delegate of the International Association of Recognized Automobile Clubs, central president of the Swiss Automobile Club; Mr. G. Milsom, Under-Secretary-General of the League of Red Cross Societies; Prof. E. J. Pampana, director of the Health and Relief Bureau of the League; M. J. Pictet, Assistant Secretary-General of the International Committee of the Red Cross; Col. E. Primault, Director-General of the Swiss Automobile Club, vice-chairman of the technical committee of the International Association of Recognized Automobile Clubs.

The Commission adopted a number of resolutions, advocating the more efficacious prosecution of the campaign against road accidents and the provision of the most modern therapeutic aids for injured people. The Commission has recommended the establishment in the various countries of traumatology services whither road victims could be transported directly and given every possible medical assistance, radiological examinations, special surgery, penicillin, blood and plasma transfusion, and adequate treatment for shock, burns, or complicated fractures. Furthermore, the Commission desired to see closer co-operation between the Red Cross and the touring and automobile organizations.

Many of the Red Cross and St. John ambulances carry on the work for which they were given in wartime. They now render a vital service to the community, especially in rural areas where problems of moving patients from home to hospital are often difficult. This service of invalid transport has grown to greater dimensions as a result of the 1939-45 war. Expansion of the services is developing in various parts of the country, and the St. John and Red Cross Home Ambulance Service is able to meet additional local needs because it has recently received nearly 500 ambulances no longer required for war service. Since its inception the service has carried hundreds of thousands of patients, either illness or accident cases; before 1914 there was practically no ambulance service for the civilian population. The headquarters of the St. John and Red Cross Home Ambulance Department at 12, Grosvenor Crescent, London, S.W.1, is a central bureau of information on all matters relating to ambulance transport. With the recent additions its fleet of vehicles now numbers nearly 1,000.

Reports of Societies

RADIOLOGY IN THE NATIONAL HEALTH SERVICE

The Section of Radiology of the Royal Society of Medicine, with Dr. W. M. LEVITT in the chair, devoted its meeting on May 17 to a consideration of the place of radiology in the National Health Service.

Dr. S. COCHRANE SHANKS claimed that "radiologists should have 'a finger in as many pies as possible,' not only in the hospital, but in the Central Health Services Council, the regional hospital boards, the hospital management committees, and even the health centres if these had x-ray installations. The Central Council was to consist of 41 members, 15 of whom must be medical practitioners, and radiologists should press strongly for one of these places on the ground of the importance of their specialty to all other branches and the magnitude of their work in the hospital. They should also have a footing in the regional hospital board. One solution might be to give the chief radiologist administrative authority in the region, but such a man might not have administrative ability, and a better arrangement would be to have a committee elected by the regional radiologists, such a committee to have a say in appointments and in such matters as the bulk ordering of equipment.

In the executive part of the service radiologists should be eligible to serve on committees of management of the hospital and to take part in the management of the medical school. The radiotherapy of malignant disease should be carried on in well-equipped centres, which would naturally be the university centres—a simple matter in the Provinces, but not so simple in London with its twelve teaching hospitals. Here some dilution of the concentrated doctrine of the therapist might be necessary, with therapy centres in each teaching hospital, but linked together for staffing, research, and record purposes. Radiologists should rank equally with their colleagues on the consultant staff, which meant more than the possession of a diploma—the D.M.R. was simply a stage in the process. In the initial stages of the service there would be but one yardstick—recognition by his compeers that a man was *de facto* of consulting rank. Where there was a private wing in a hospital it seemed only right that the hospital radiotherapist should have the privilege of treating private patients. The case of the diagnostician was more complicated, as so much of his work was with out-patients. In future there would be an inevitable diminution of private work, and with the mounting cost of installations few radiologists would care to face the expense of private consulting-rooms and would be driven to do their private work at hospitals.

The radiologist should have effective charge of all the x-ray services of the institution in which he worked. There was a growing tendency in diagnostic departments to "nuclear fission, particularly under the impact of orthopaedic neutrons." If there were subsidiary units, such units and the radiographers working in them should be part of the main department and under the direction and control of the radiologist, and every film taken in the subsidiary unit should be seen and reported on by the radiological staff. As to academic status, radiologists were called upon to do little undergraduate teaching, but postgraduate teaching was a different story. In London there were about 80 postgraduates under training this year for the D.M.R. A chair of radiotherapy was established in London, but there should also be a professor of x-ray diagnosis, and professors in these subjects should be established in other university centres wherever systematized postgraduate instruction in radiology was given. The distribution of radiology in the future would be not only in teaching and in district hospitals but also in cottage hospitals, special hospitals, health centres, tuberculosis clinics, and mass radiography units, as well as in domiciliary service in the patient's home. Dr. Shanks expressed the view that 2,000 radiologists might be necessary to carry out the service of the future—a multiplication of present numbers by three.

Need for More Radiologists

Dr. A. E. BARCLAY wrote agreeing with Dr. Cochrane Shanks that an adequate radiological service on a consultant basis would need three times the present number of radiologists. Nothing had impressed him more during the war than the

reed for more radiologists. It had been distressing to see men endeavouring to cover more work than could properly be accomplished and being compelled to delegate far too much to the radiographer.

Dr RICHARD FAWCETT described the results of a questionnaire which he had addressed to a number of his fellow radiologists in non-teaching hospitals in different parts of the country. Most of the radiologists of whom inquiry was made—30 out of 35—served more than one hospital, a number served far too many hospitals occasionally in more than one county. The overwhelming majority of those approached carried out private practice at their hospitals. In the larger number of non-teaching hospitals, radiotherapy, except for superficial work, such as the treatment of skin conditions, was seldom justified unless under the direct supervision of a member of the staff of a recognized therapy centre usually a university centre. Normally the non-teaching hospitals particularly the smaller ones had no physicist and in many cases only restricted pathological facilities. They were accordingly often not in a position to make a diagnosis of—let alone to treat—cases requiring deep therapy and radium. This view was endorsed very widely by those whom he had approached.

Dr G B STEBBING said that in the Bill the composition of the regional hospital board was left vague, they should do all they could to see that the board was composed of people really expert in hospital management. As to the functions of local management committees, he recognized that local government hospitals were as a rule inferior to voluntary hospitals owing to over-centralization of management. The management committees in local authority hospitals should have as much power as voluntary hospital management committees had now. One of the reasons why there should be more radiologists was the consultant status of the radiologist, the best service would never be obtained until consultations took place in front of the patient instead of on the basis of reports.

Dr WHATELY DAVIDSON said that it was wrong to think of treatment or investigation of patients in terms of standardization. The only standardization which was justifiable was the establishment of minimum standards of staffing and equipment. He was quite certain that radiological control of technique was essential. Dr A S JOHNSTONE said that large numbers of highly trained young men in medicine who had had adequate hospital experience were frightened off diagnostic radiology because they had to turn back and take their physics over again. He suggested that some of the knowledge of physics demanded of the radiologist was unnecessary. In a well-planned department there should be sufficient radiologists for each to be attached to one physician or surgeon or to a special department and to carry on consultation work within his own orbit.

Dr GRACE BATTEN agreed with Dr Stebbing as to the disadvantage of over-centralization as seen in local authority hospitals. It often meant that no notice was taken of the opinion of the person on the spot. It ought to be insisted that full account be taken of local expert opinion so that really essential matters were not liable to be set aside by lay people who knew nothing about the subject. Radiologists should insist on the localization, not the centralization, of authority. Dr H C H BULL referred to the conditions in Sweden, where the rule was for the radiologist himself to see every patient. Radiology, he said held a higher position in Scandinavia than it did in Great Britain. In Scandinavian provincial hospitals the first specialist to be appointed was the surgeon, but the second was the diagnostic radiologist.

The PRESIDENT (Dr LEVITT) said that evidently all was not well in the realm of radiology. Whether the proposed new scheme would remedy matters remained to be seen, but there was this to be said for a planned service, that the responsibility did rest with one person. He felt that the introduction of a service with responsibility centralized did at least offer the hope of a remedy.

The British Standards Institution has recently issued specifications for high carbon steel cylinders and manganese steel cylinders for the storage and transport of carbon dioxide, nitrous oxide, and ethylene. Copies of these British Standards No 1287 and No 1288 may be obtained from the British Standards Institution, 28, Victoria Street, S.W. 1, price 2s. each post free.

Correspondence

Correction of Medical Register

SIR—I am desired by the Returning Officer to say that voting papers for the purpose of the election of five members of the General Medical Council to represent the registered medical practitioners resident in England were issued on May 28 to all practitioners having registered addresses in England, and that the authorities of the Council would be glad if any such practitioner who did not receive a voting paper would communicate with the office of the Council (44, Hallam Street, London, W. 1), in order to ascertain that his address is correctly entered in the *Medical Register*—I am etc.,

C WESTON,
for Registrar

London W. 1

Epidemiology of Influenza and Cholera

SIR,—My attention has recently been drawn to your annotation (Aug. 7 1943 p. 175) on "The Nature of the Influenza Virus," in which you write that one of the great mysteries in the epidemiology of influenza is the mechanism whereby the virus survives through long interepidemic periods. At the same time you refer to the then recent work of Shope (*J. exp. Med.* 1943, 77, 111) on swine influenza and express the opinion that the most interesting feature of Shope's work is his demonstration that swine influenza virus, while in the lung worm, exists in a masked form and is totally non-infective until awakened to activity by some provoking stimulus. You state that Shope thinks that the onset of a swine epizootic is determined, not by the acquisition of the causative virus, but by meteorological or physical conditions which favour virus activation, and express the opinion that it would be unwise to ignore the possibility of a similar mechanism existing in human beings. Finally, you draw attention to the fact that human epidemics like swine epizootics, usually occur during a particular season of the year and that epidemic foci often arise simultaneously and apparently independently, suggesting some activation of previously acquired infection rather than direct case-to-case transmission.

In their joint investigation into the bacteriology and epidemiology of cholera in the Asansol Mining Settlement, Bengal on behalf of the Indian Research Fund Association and the Calcutta School of Tropical Medicine Tomb and Maitra (*Indian med. Gaz.* November, 1926 p. 537) arrived at a conclusion regarding the epidemiology of cholera in close accord with that subsequently arrived at by Shope regarding swine influenza. In an article entitled "A New Conception of the Epidemiology and Endemology of Cholera" (*Indian med. Gaz.*, February, 1927, p. 61) they wrote as follows:

"We have therefore been driven to the inevitable conclusion that the non-agglutinating (non-infective) vibrio takes on the agglutinating (infective) characteristic under certain biochemical-physical conditions [often seasonal] in the human intestine, the nature of which is at present unknown, and in this mutation or infective form is the cause of epidemic cholera. Non-agglutinating (non-infective) intestinal vibrios, therefore, in our opinion constitute the reservoir of cholera both epidemic and endemic."

In the previous article (1926) they also wrote "During our investigations in the Asansol Mining Settlement we have met with several outbreaks of epidemic cholera in distant and isolated villages the inhabitants of which had not been in contact either recently or remotely with any case of epidemic cholera. Spontaneous outbreaks of epidemic cholera have also been noted by other observers in other localities. Hitherto the explanation of such outbreaks has been that they owed their origin to some carrier of Koch's (infective) vibrio who existed unknown in the community. Our suggested explanation of such outbreaks now is that owing to favouring circumstances [often seasonal] the non-agglutinating (non-infective) vibrio changes into the agglutinating or epidemic form in one of the numerous chronic carriers of non-agglutinating vibrios in endemic areas [such as the Mining Settlement], the epidemic spreading in the usual manner by contamination of water and by contact." I am, etc.,

Sydney N.S.W.

J. WALKER TOMB.

Hernia and Strain

SIR,—During the last five or six years it fell to my lot to operate on large numbers of recently acquired inguinal herniae in young men. Not infrequently the history was of the sudden appearance of a swelling in the groin consequent upon some particular effort. In these cases it was no uncommon thing to find, after removal of the sac, that the internal ring was much enlarged, and on displacement of the cord it was apparent that this enlargement was caused by an actual tear of the transversalis fascia, which extended through the thickened inner margin of the ring for a variable distance across the canal. The tear exposed the deep epigastric and iliac vessels and allowed a finger-tip to slip back quite easily into the extraperitoneal cellular planes of the pelvis. Moreover, its edges were clearly defined, and a single line of suture uniting them was sufficient to restore the normal anatomy of the canal. Oddly enough, the resulting hernia was not always "direct." Protrusion still took place laterally to the deep epigastric vessels, which, of course, offered no resistance and were displaced medially.

Obviously, with a lesion of this kind the first step towards cure after removal of the sac must be directed towards closing the tear, preferably with unabsorbable material. To hope for success by building up a barrier at an anterior level would be on a par with trying to keep the horse in the stable by shutting the yard gate. The other point that arises in connexion with these cases concerns liability. I believe that with a clear history and the operative findings which I have described the surgeon would have no choice but to describe the lesion as "attributable."—I am, etc.,

London, W.1.

STEPHEN POWER.

The Catheter and the Prostate

SIR,—Mr. Wilson Hey states (May 18, p. 757) that the mortality rate in 565 consecutive cases of prostatectomy performed by him was 4.3%, and also that "suprapubic drainage for any form of prostatic obstruction should be abandoned." It is a matter of historical interest and clinical significance (*Enlargement of the Prostate*, Freyer, 5th edition) that the late Sir Peter Freyer performed 1,337 prostatectomies, every one of which had suprapubic drainage, with a mortality rate of 4.77%.—I am, etc.,

CLIFFORD MORSON.

Suprapubic Drainage of Bladder

SIR,—As the controversy over the merits or demerits of blind (trocar) or open exposure of the bladder appears to be resolving itself into a matter of "ozs." capacity of the bladder or its "cms." distance from the upper border of the symphysis pubis, variously estimated by the anatomist or the surgeon, I feel what matters materially is the danger element—the peritoneum. The trocar method merely has a dramatic appeal, despite its occasional failure or subsequent obviously possible complications of a serious or even fatal nature. The latter method should have a greater appeal to the operator well acquainted with anatomy, in that its simple technique under local anaesthesia is a "precise" operation, requiring very few minutes in its performance. The late Mr. Wilfred Trotter instilled the teaching, "When you operate, do something definite," and again insisted upon "exposing the danger in the field of operation," and "so avoiding it during the subsequent steps of the operation." Bearing this in mind, the choice of open operation is undoubtedly the more safe procedure.—I am, etc.,

Bridgwater.

G. C. SNEYD.

Treatment of Syphilis

SIR,—In your leading article entitled "Progress in the Treatment of Syphilis" (May 18, p. 766) you state that "60 mg. mapharside is the equivalent of 600 mg. neosarsphenamine." I am aware that this statement has been made before, but I should like to know on what grounds, because (1) you say that if one injection is given per week neosarsphenamine (600 mg.) is superior to mapharside (60 mg.), and (2) in the only straight comparison between the two drugs of which I am aware—the 5-day intensive method—about three and a half times as much neosarsphenamine as mapharsen was required to produce equal

results. Your reference to "the poverty of the data recorded in papers from this country" is hardly fair on British syphilologists because (1) penicillin was not available for the treatment of syphilis in this country nearly so early as it was in the U.S.A., and (2) we hesitate to publish until we are sure of our ground.

Incidentally you make no reference to the brilliant work of Nicol *et al.* in the malaria treatment of G.P.I., which in my opinion is far more valuable than the report of a committee in 1940 which you quote. I worked in the closest co-operation with the Americans during the war and saw their methods both in England and in the U.S.A., and consequently have the greatest admiration for them, but I see no reason why you should disparage our own workers by making "odorous" comparisons.—I am, etc.,

Ashford, Middlesex.

T. E. OSMOND.

SIR,—May I venture to point out that your leading article on progress in the treatment of syphilis (May 18, p. 766) does less than justice to the contributions of British workers. No one would wish to minimize the achievements of our American colleagues, but it is difficult to avoid the feeling that you, Sir, have perhaps been over-impressed by the mere wholesale scale of their experiments. Is there any real justification for crediting the Americans with "greater grasp of the principles of drug action" than workers in this country? You praise them for having already by 1944 published results in 1,418 cases of early syphilis treated with penicillin,¹ and lament the paucity of data from this country. These 1,418 cases were treated by total dosage schedules ranging from 60,000 to 1,200,000 units—that is, ranging from grossly inadequate to inadequate—and you point out that high hopes had later to give way to more modest expectations. I find it difficult to share your enthusiasm for an experiment in which 1,418 patients were used in order to point the moral which was reached by ourselves² in the same year with only 5 patients—namely, that 1,200,000 units is probably insufficient for cases of early syphilis; in other words, that 1,418 patients had been inadequately treated by a substance which could quite safely have been given in considerably higher doses. Let us hope that your enthusiasm for this experiment will not encourage similar methods of investigation in Britain.

Again, you write that it is not very surprising that it was the Americans who first discovered the value of penicillin in syphilis. Indeed it is not very surprising, since it was in the United States alone that sufficient penicillin could be spared in 1943 for trials in human syphilis. It is, however, unjust to give exclusive credit to American workers for this development of penicillin therapy. The initial discovery of the activity of penicillin in spirochaetal infections in laboratory animals was made in Liverpool in August, 1942. The late Prof. Warrington Yorke made no secret of this information, or of its significance for human syphilis, during his visit to the United States on behalf of the Ministry of Supply in September and October, 1942. It was mentioned in the published annual report of the Liverpool School of Tropical Medicine for the year ending July 31, 1943,³ and full details were given in the *Annals of Tropical Medicine and Parasitology* for December, 1943.⁴ It was in the latter month that the American announcement was made of successful trials in man.⁵ Now it is well known that during this period—August, 1942, to December, 1943—there was the utmost stringency in the allocation of penicillin in this country on account of the need for conserving stocks for the treatment of battle casualties in the impending invasion of Europe and elsewhere. In the United States, on the other hand, penicillin was already available in relative abundance during this period, thanks to activities aroused there by the visit of Sir Howard Florey in 1941. It is for these reasons that we need not be surprised that it was the Americans and not ourselves who were to follow the lead given by the prior discovery of the activity of penicillin in experimental spirochaetoses.

In your recapitulation of the development of intensive schemes of treatment the impression is conveyed that this has been an exclusively American field of enterprise. (You quote eight American and no British papers in this connexion.) May I remind you of at least one scheme of intensive therapy which was initiated in this country. For more than 20 years

I have, against official opposition, fostered here in Liverpool courses of intensive treatment lasting only 39 days"—a scheme which, with only slight modifications, was at last officially recommended in 1943 by the Ministry of Health.—I am, etc.,

* The views expressed on May 18 were based on observation of American work at close quarters, and the purpose of the article was to stimulate further activity in this country. There seemed good reasons for believing that the experimental trials in America were conducted with great care and that the results were considered most critically. There is no doubt that the Americans, in devising their clinical trials of short courses of mapharside, paid great attention to the laboratory findings in experimental syphilis and based their trials on the principles which the laboratory results established. Hence the reference to the "greater grasp of the principles of drug action." The collaboration, for example, between Dr. Earle Moore on the one hand, who is able to plan large-scale clinical experiments, and Dr. Eagle on the other, to advise on the laboratory findings, has no real parallel in this country. It is difficult to reply briefly to Brig. Osmond's question concerning the relative value of mapharside and neosarsphenamine, but it can at least be said that the statement made in the article is fully accepted in the United States.—ED., *B.M.J.*

The Teaching of Human Anatomy

SIR.—I have just read the letter (Nov. 24, 1945, p. 740) on this topic. It would give me great pleasure to add my name to the 30 signatures among which I note the names of many friends, including one of my own teachers. May I send a greeting to all?

I should view the position in which the teaching and examining of medical students in anatomy were undertaken by one who did not possess medical qualifications with the gravest misgivings. The stress of war with the will to victory at any cost no doubt has led to shortage of teachers and improvisations in teaching which can be excused. The possibility that this practice might find a permanent niche in our teaching arrangements should be resisted with resolution if the high standard of our British medical curriculum with its traditional anatomical bias is to be maintained.

It frequently happens that I, being a teacher of anatomy, am addressed as if I were possessed of the highest of diplomas in surgery. I wish it were so; but it is the *non sequitur* that I do not understand. In my opinion a knowledge of anatomy with physiology and pathology lies at the root of rational diagnosis. The application and usefulness of this knowledge are very far from being limited by the artificial procedures of the surgeon. It only strengthens my view on the main thesis regarding the teaching of anatomy. These remarks may be trite, but an anatomical *credo* at times can be of no harm.—I am, etc.,

L. R. SHORE, (ex-P.O.W.).

Professor of Anatomy, University of Hong Kong.

* Prof. Shore's letter is written from the General Hospital, Lower Hutt, New Zealand.—ED., *B.M.J.*

Fibrositis

SIR.—Unlike Dr. H. G. Garland (May 18, p. 774), I believe that the term "fibrositis," in its modern usage, describes a clinical entity. Dr. Garland offers no alternative term. In fact one gets the impression that Dr. Garland believes there is no such condition, and that when the term is used a misdiagnosis has been made.

Dr. Garland is a neurologist, and in that quiet backwater of medical practice the flotsam and jetsam of everyday experience

is seldom found. I can assure him that orthopaedic surgeons see many painful conditions of the muscular parts of the body, unassociated with other discoverable pathology, and which recover even without treatment. I myself have recently suffered from a painful right trapezius, following a long cold day at an open driving-window, and I can assure Dr. Garland that I have enjoyed excellent health since and that so far I have no symptoms or signs of chronic empyema, lobar pneumonia, metastatic carcinoma of the spine, or prolapsed cervical intervertebral disk. I have also seen many patients complaining of a painful back and of pain down the backs of the thighs ("sciatica"), who attributed the condition to "sitting in a draught," and the absence of other abnormal signs and subsequent recovery gave me no reason to suppose that their explanation probably was not the correct one.

Isn't there now merely a fashionable tendency to label the conditions hitherto called "fibrositis" and "sciatica" "prolapsed intervertebral disk"? Dr. Garland knows that when such a label is attached, even by a neurologist, a prolapsed disk is not always found at operation. If in the past a rubbish heap has been made of "fibrositis," I maintain that there is a danger of the neurologists making a rubbish heap of "prolapsed intervertebral disk."

I know Dr. Garland will be the first to agree with me that what his letter really emphasizes is the necessity for accurate diagnosis. Then no longer will chronic empyema, lobar pneumonia, metastatic carcinoma, and prolapsed disk be misdiagnosed as "fibrositis" or "fibrositis" as prolapsed disk.—I am, etc.,

London, N 15.

J. S. MAXWELL.

Smallpox in the Vaccinated

SIR.—The following report on four cases of smallpox may be of interest. The cases occurred on a troopship returning from Bombay in February, 1946, where smallpox was present in epidemic form at that time. Only the salient features of each case are given, as this letter is not intended as a clinical description of smallpox but rather to stress the necessity for the adequate vaccination of those coming from, or going to, areas where smallpox is endemic.

Case No. 1.—An airman reported sick on Feb. 12 with a rash. Temperature normal; no increase in pulse rate; appetite good; no constitutional disturbances. Diagnosed as "infective acne." Three days later on routine inspection of troops on board discovered with a pustular eruption; isolated immediately for the remainder of the voyage. I saw him the day following isolation, and he certainly had marked acne on the chest wall and back, but he now had a definite pustular eruption, mainly on the scalp, face, arms, legs, and trunk, with two or three definite pustules on the palms of both hands and feet. He had never had chicken-pox and had been vaccinated two or three times during the war, the last vaccination being eight months previous to embarkation; one scarification only, but, from the appearance and extent of the scar, could be considered to have quite a good "take." At no time during his illness did he suffer any constitutional disturbances; in fact it took a good deal of explaining to him why he was held in isolation.

Case No. 2.—The medical officer who first saw case No. 1 was taken ill on Feb. 23, 1946, complaining of severe headache and backache. Evening temperature swinging between 102° and 104° F. (38.9° and 40° C.). Repeated bloods were taken and examined for malaria parasites; all were negative. He was treated as a clinical malaria. On the fourth day the temperature dropped to normal and the eruption appeared, mainly on the trunk, thighs, and arms. Feet and hands were clear. The eruption was definitely "shotty" to the touch and was all at the same stage. The patient had been vaccinated in 1945 but had not taken.

Case No. 3.—Admitted to ship's hospital Feb. 25 with pain in the right epigastrium and high fever. Diagnosed as diaphragmatic pleurisy. The patient was put on sulphapyridine, and after twenty-four hours developed a scarlatiniform rash which at the time was attributed to sulphapyridine. On the fourth day a massive eruption appeared all over the man's body; in fact it was hardly possible to place a pin anywhere free from the eruption. The patient was extremely ill and subsequently died. He had been vaccinated during the war, but I am not in a position to say whether he had "taken."

Case No. 4.—Mild general disturbance with minimal rash. Hospitalized Feb. 25.

Cases Nos. 1, 3, and 4 were all from one troop section, and case No. 2 was a direct contact with case No. 1. Gordon's

test was positive in all four cases. These four cases illustrate what is already well known, but it might not come amiss to stress again that a modified attack of smallpox may be handed on in malignant form to an inadequately vaccinated person, and, secondly, that inadequate vaccination by one scarification can so modify typical smallpox as to render it easily missed. The primary defence line in these islands is the Port Health Authority; behind them lies a mainly unvaccinated population, likely to be more unvaccinated still in the near future. There are different opinions amongst the medical profession as to when and how often vaccination should be performed, but no one doubts the efficacy of vaccination against smallpox.

There will, in the near future, be large movements of troops and civilians to and from countries where smallpox is endemic, and this letter is a plea that the persons involved in these movements should be adequately vaccinated. By adequate vaccination I mean at least three scarifications. How many of us are content to make one scarification only? How many of us are content to give a certificate of vaccination if there is no "take" without repeating vaccination three times? How many of us are particular that the vaccine used is of recent date of manufacture?—I am, etc.,

F. K. BEAUMONT,

Surgeon, Canadian Pacific Steamships.

Liverpool.

SIR,—Dr. W. F. Corfield (May 18, p. 775) gives particulars of 14 cases of smallpox which have recently occurred in Essex, and which illustrate the well-known fact that the fatality of smallpox is higher in the unvaccinated than in the vaccinated. He then asks if I consider that this protection is not worth having? My reply is: "Yes, certainly, as regards the individual, but not necessarily so as regards the community." Let me explain. Dr. Corfield suggests that if the population had been completely unvaccinated many contacts with the soldier (a highly modified case) who was the cause of the outbreak would have contracted virulent smallpox. I agree that is very probable. But Dr. Corfield omits one important point—viz., Was this soldier vaccinated or unvaccinated? I think I am justified in assuming that he was vaccinated (and very possibly revaccinated); and I further assume that his highly modified attack was due to his having been vaccinated, and that it was because his attack was so highly modified that he caused the outbreak. I may be wrong, but this is the usual sequence of events. I suggest that had he been unvaccinated it is probable that the nature of his illness would have been recognized earlier, and then there might not have been an outbreak at all.

Experience has shown repeatedly that these highly modified cases of virulent smallpox which result from vaccination are a very real danger to the community, although admittedly the individual benefits. Indeed, it is hardly an exaggeration to liken them to the foxes with lighted firebrands attached to their tails which Samson, according to the story, turned loose in the standing corn of the Philistines with disastrous results. However, in the future there will be far fewer soldiers returning from the East, so this source of danger will be diminished.

Incidentally, it is rather remarkable that apparently only 3 of Dr. Corfield's 14 cases were unvaccinated. Smallpox to-day does not seem to "pick out" the unvaccinated to the extent that it was once supposed to do.—I am, etc.,

Leicester

C. KILLICK MILLARD.

The Population of India

SIR,—It appears to me at once fantastic, inhuman, and unscientific to describe India's problem as an excess of population. Unfortunately, Dr. Annie Megaw Brown (May 25, p. 811) is not alone in falling into this error. It is the old, exploded Malthusian fallacy, which, though out of fashion in Europe, continues to be applied to Asia as a means of salving our consciences and disclaiming all moral responsibility for the state of affairs in India. When food is short in Britain we do not view the problem as "Too many Britons," though we are well aware that we have more people than we can support on the produce of our own soil.

India's problem, like that of many other countries at the present time, is shortage of food, and this will not be remedied by efforts on the part of Europeans—no matter how well meaning—to alter the marital habits of the Indian peasant. India's immediate need is additional imports of grain, which can be obtained only by displaying less favouritism to ex-enemy

countries and by self-sacrifice on the part of countries like the U.S.A. with a comfortable margin of safety.

As to the future, there has been a whole spate of plans showing how India can greatly increase the amount of food grown. In the technical field India would have no difficulty in supporting a much larger population if she so wished. The difficulty lies in achieving a political and social structure which will permit of large-scale economic planning.—I am, etc.,

St. Mary Cray.

BRIAN H. KIRMAN.

Artificial Sunlight in Industry

SIR,—In a report just issued on behalf of the Industrial Health Research Board about "Artificial Sunlight Treatment in Industry" (H.M. Stationery Office, Report No. 89) Dora Colebrook, while referring to previous experiments, deals, among others, with the work done by myself in 1943 at the Kirkby (Notts) Colliery (*Brit. J. phys. Med. industr. Hyg.*, 1943, 6, 105). Scrutinizing the figures published about the result of treatment in another article later on, she declines to accept my suggestion that the 18% drop in the mean sickness absence rate in 1943 when compared with the figures of the same period in 1942 should be *de facto* due to the artificial sunlight treatment carried out in a specially built solarium at that colliery in 1943.

Dr. Colebrook's argument against such an acceptance is that the percentage of the mean sickness rate at the "control" colliery in 1942—i.e., previous to the experiment described—has been nearly half only (3.6% as compared with 7.3%) of that of the Kirkby Colliery during the same period. Furthermore, that even during the experimental period in 1943, "when the Kirkby miners were irradiated, they lost time at the rate of 6%, whereas the rate for the men at the 'control' colliery was only 4.7%" (italics are mine). A little reflection will quickly reveal to everyone interested in the subject that Dr. Colebrook has lost herself here in the jungle of statistics and made a fundamental mistake by comparing the absolute mean sickness absence figures of two different collieries, whereas the thing that decides the issue really is what changes in the figures of absenteeism through sickness took place at each individual colliery.

Everyone who is in touch with a group of collieries knows very well that each colliery has its own feature regarding absenteeism (both voluntary and involuntary). The range of difference in this respect is very wide indeed. It would transgress the scope of this letter to describe here the underlying causes, but it is a well-known fact. One glance at my figures shows that Kirkby belongs to the group of collieries with a higher absenteeism rate, and the "control" colliery to that of a lower category, but these general characteristics remain fairly irrelevant when trying to judge the fact whether or not the solarium treatment has had any influence on the figures of absenteeism at the colliery in question. The crucial question here remains, What were the figures before and what during and after the treatment period? The fact that an 18% decrease of absenteeism during and after irradiation treatment took place at the Kirkby Colliery, which, generally speaking, has a poorer health standard, while during the same period absenteeism figures of the better-health-standard "control" colliery, where no irradiation took place, have increased from 3.6% to 4.7% is not an argument against my conclusion, but, in fact, it underlines it.

I am also at a loss to understand why Dr. Colebrook describes my observations as "limited both in space and time," when they extend to a period of half a year, while her own corresponding colliery experiment, to which she attributes fundamental importance, has been carried out during three and a half months only. Also the number of men involved at my colliery has been considerably bigger than in her experiment.

Similar, and some even more far-reaching, mistakes occur at many stages of Dr. Colebrook's observations, which were bound to lead her astray and to wrong conclusions. One feels deeply sorry that trials at which such a lot of thought, honest work, and painstaking efforts have been employed, through a certain lack of circumspection, should have had the result of only obscuring even more an already complicated and difficult problem.

I propose to substantiate later on with a detailed survey my present criticism. Meanwhile, may I, as someone who for

more than twenty-five years had opportunity to study the effects of ultra-violet irradiation, utter a serious warning: anyone who would accept the findings of this report at their face value and would draw the necessary practical conclusion from it (which ought to be tantamount to a negation of any value of the artificial sunlight treatment) would be running a grave risk and may easily cause grievous harm to a national cause of great importance—to the health and well-being of the industrial worker.—I am, etc.,

L. SCHMIDT,

Consulting Physician and Medical Supervisor
to the Rheumatism Clinics of the Butterfly
Collection and Workshops

Oyster Hall, Newark.

* A leading article on Dr. Colebrook's report appears on page 882.—Ed., B.M.J.

Drugs and the National Health Service

SIR.—The high cost of new drugs and apparatus is defended by the manufacturers as a necessary part of research costs. Before the war the Government provided a limited sort of protection to the public against unfair or prohibitive prices for a few very important drugs like insulin; but the early costs of the more effective sulphonamides were only to be met, for working people, through the hospitals, and for several years one of the most effective—sulphadiazine—was sold at a price which made the research which had gone to produce it benefit only the well-to-do. Now folic acid, which, if claims are justified, will replace liver injections in the treatment of pernicious anaemia and sprue, and which will cure certain hitherto refractory anaemias, is to be marketed at 3s. a tablet, the effective daily dose being about four tablets. During the war Fleming's discovery of penicillin as a remedy was exploited exclusively by the Government for the people as a whole and was supplied free—i.e., the whole cost falling on taxation; it is now to be sold at a controlled but not negligible price.

You will agree that the health service must not run the risk of incurring the criticism levelled at panel practice, of limiting the cost of drugs and apparatus prescribed, and surcharging the "extravagant" doctor. But neither must it be possible for fortunes to be made out of drugs at the public expense. I believe there are no advantages accruing to the commercial exploitation of pharmacy and instrument manufacture in the direction of independent research and cheapness of manufacture which are not outweighed by permitting the advertisement of doubtful, inferior, or unproved remedies. The solution of this problem, as has been magnificently demonstrated in the case of penicillin, is the endowment of research laboratories in the universities and in association with a nationalized drug industry, experimental work being encouraged in the health service whenever conditions allow of reliable results. The field of commercial "private enterprise" should be limited to cosmetics and the simpler kinds of home remedies.—I am, etc.,

Inverness

D. G. LEYS.

The Health Service Bill

SIR.—Those of us who believe that the passing of the National Health Service Bill will result in a better medical service for the country must make it our chief concern to ensure that bureaucracy will have no place in it. Mr. Bevan, in the Second Reading of the Bill, described democracy as active participation in administration and policy; this can only be attained by the medical profession and those in the ancillary services by the recognition of staff committees in all spheres of activity and with adequate representation of the professions at all levels of the administration.

The active participation of the consumer—the general public—will take place through the representation of the local authorities, but many feel this is too remote and indirect, especially with the regionalization of the hospitals. Many of the hospitals at the present time have inspired a devoted body of voluntary workers who take a local pride and a personal interest in the hospital situated in their area. I suggest that a voluntary workers committee, drawn from the various organizations in the locality of a hospital or group of hospitals, should be formed with representation on the Hospital Management

Committee. This would stimulate local interest and local feeling of responsibility and provide a direct link between the hospital and the people in the area.—I am, etc.,

Birmingham

M. BARROW.

SIR.—It seems probable that all doctors come up against samples of "the shape of things to come" under a State-directed medical service, and it might be of use to collect such samples and publish them. It should not be less helpful than the publication of a great many letters which contain only generalizations and hypotheses.

This small town, which serves a large rural area, is blessed in the possession of a very well built, well-equipped modern hospital, but the profession in the area has recently been informed that the local education authority will accept financial responsibility only for children who are sent to designated hospitals in Plymouth (25 miles), Exeter (42 miles), and Truro (47 miles). For my own part I am prepared to agree that major surgery should not be conducted in any hospital when no resident is employed, but to find oneself eliminated from all part in the treatment of one's child patients who need hospitalization is more than a little startling.—I am, etc.,

Launceston

DONALD M. O'CONNOR.

Hospital Survey of East Anglia

SIR.—Your brief note on the hospital survey in East Anglia (May 18, p. 771) calls for a little comment, which I venture to make, and I hope you will accept, because the report is not at all fair to Peterborough Memorial Hospital. The visitation to the district took place in October, 1942, and the Ministry of Health survey was based upon that visit. Since 1942 Peterborough Memorial Hospital has made the following advances among others: (1) Installation of the medical superintendent with clearly defined powers and responsibilities. (2) Arrangements for full-time salaried specialists. (3) Enlargements of the theatre, x-ray department, and pathological department, with new building in all three. (4) Foundation of a maternity wing. (5) Establishment of a rehabilitation department. (6) New and enlarged programmes of consultation clinics. (7) A doubling of the general work of the hospital.—I am, etc.,

G. F. WALKER,

Medical Superintendent and Physician.

Peterborough and District Memorial Hospital.

In the Words of Eliza Doolittle

SIR.—Some months ago I formed a "local" Spens Committee under the inexperienced chairmanship of myself. It consisted of a butcher, a baker, a candlestick-maker, a banker, a school teacher, a bricklayer, a bookmaker's "runner." The question put to each of them was this: "What remuneration would you expect if you were offered a job on the following terms? Your hours will be from 9 a.m. till 9 p.m. daily with two half-hours off for meals. Your meals may be undisturbed, but you are quite likely to be interrupted on several occasions just to sign a small piece of paper or to give a word of advice. From 9 p.m. till 9 a.m. you are free, but must be prepared to go to your place of work if called upon. You may be away for only half an hour at a time, and with luck may not be called on at all, but you must be prepared at all times to come if asked. On one half-day a week you will be free about 2 or 3 or 4 p.m. under the same conditions as your 9 p.m. freedom of other days. On Sundays you need not appear at your place of work, but must be ready to come if called upon, probably on at least half a dozen occasions. You can go on a holiday if you like or be ill if you dare, but only if you arrange for a fellow-worker to take your place and be responsible for his wages, board and lodging, and means of transport. On public holidays you are very likely to be required, as all fellow-workers in Government and municipal employment will be on holiday, and even if they have skeleton staffs at work these will not be as available as you. You may be single if you choose, but it is to be hoped that you are married, as your wife or someone must be prepared to answer all calls made at your home, and no single woman outside of Bedlam is likely to be willing to shoulder that responsibility. You are never likely to reach the age of

65, so the question of superannuation on retirement need not arise."

Such were the terms of the offer. The question was put: "Would you consider taking on this job at £1,500 per year?" The committee's reply was the shortest in the history of such commissions. It was unanimous and consisted of three words only—the three words that brought immortality to Eliza Doolittle in Shaw's *Pygmalion*.—I am, etc.,

Glasgow.

ANDREW S. BARR.

The Future of Nursing

SIR,—Dr. C. M. Billington (May 25, p. 814) calls attention to a Gilbertian situation which has a tragic side while all over the country hospital beds are closed for lack of staff. An R.A.M.C. staff sergeant who desires to continue nursing must take a job as a bus conductor because he cannot afford to use his acquired professional skill and thereby deprive his family of 28s. a week. In the *Times* and in medical and nursing journals a well-balanced scheme has been promulgated whereby basic nurse training could be shortened to two years followed by post-certificate qualification in special lines. Perhaps the staff sergeant's case may stimulate thinking in those who seem to prefer to keep beds closed rather than amend the *status quo* as regards the conditions and pay of nurses.—I am, etc.,

Moor Park, Northwood.

ESTHER CARLING.

SIR,—It is important that the R.A.M.C. sergeant about whom Dr. C. M. Billington writes, and all other ex-Service men and women with nursing experience, should have up-to-date information on the facilities now offered them. In particular, it is entirely untrue that no R.A.M.C. experience counts in civil nursing. If this sergeant has had two years' nursing experience in hospital under the supervision of trained nurses he is eligible for a remission of six months in the training course. The question of arranging much shorter courses at special rates for ex-Service men and women who hold Class I Nursing Orderly qualifications is now being considered by the Ministry of Health.

On the question of salaries also there are considerable advances beyond the rates quoted. Once qualified he would command the new staff nurse's rate of £5 a week, rising to £6 a week, then to £7 6s. a week as charge nurse, and ultimately to £420 a year as superintendent nurse. The rates are from 5s. 6d. to 9s. 6d. a week higher than this in the London area.—I am, etc.,

London, W 1

MURIEL M. EDWARDS,
Secretary, Nursing Recruitment Service.

Alien Doctors in Britain

SIR,—In view of the fact that I am finding myself in exactly the same position as described in the *Journal* of May 18 (p. 776) I wonder whether you would kindly publish the following.

I have been recently released from the Forces after four years of service here, West Africa, India, and S.E.A.C. During the years in question I have attended thousands of British and Imperial troops and looked after the welfare of scores of Englishmen. I have worn the same uniform as my British colleagues, and that the same rights went along with the same obligations was never questioned by anyone. As matters stand now I am unable to secure any appointment, either hospital or as an assistant, doctors and the hospital authorities being reluctant to employ a "temporarily registered" doctor. In fact the position is a grim one, as I am slowly but surely drifting into destitution and shall be compelled eventually to take any unskilled occupation that comes in order to earn a living and support my family.

I wish to add that I am of Polish nationality and have recently learned of the complete extermination and destruction of my people and home respectively during the German occupation. In addition my home town is now within the boundaries of another State, and I cannot return to my country. Is there any hope left?—I am, etc.,

London, N.W.11.

ERNEST M. THORN.

Obituary

W. McADAM ECCLES, M.S., F.R.C.S.

The news of the death, on May 30, of Mr. McAdam Eccles, consulting surgeon to St. Bartholomew's Hospital, will be received with sorrow in many circles. Almost to the end he was identified with an extraordinarily large number of interests—medical, sociological, and religious. He dispersed his activities over a wide area, and gave even to quite small matters an enthusiasm and energy which suggested a man in his prime. He was as much at home at a meeting of Presbyterian elders or in a little group of scientific photographers as in larger assemblies which he was able to move by a gift of lucid public speech. A few months ago he declared that he was resolutely severing himself from obligations in London. It meant, he said, cutting himself off from nearly forty organizations in which he held some official position. This was his second retirement, his first having taken place at the age of 60—to him an age absurdly low—when he left the active surgical staff of St. Bartholomew's. He had found rather more to do after that retirement than before it, but this time, he said, he was really giving up active employment and going to live with a sister in rural Kent and devote himself to a garden, though he would retain one link with London, journeying up once a week as medical officer of one of the insurance corporations.

(Photo: Whitehead)

William McAdam Eccles, who was born in 1867, came of a family of doctors. His father was Dr. W. Soltau Eccles of Norwood, and his grandfather was a doctor also; but another line of ancestry of which he was also proud was from John Loudon McAdam, the Scottish inventor who gave his name to the system of road-making known as "macadamizing." He was educated at University College School, went on to University College, and then to his medical training at St. Bartholomew's, the hospital of which he was very proud and with which he was to be identified to the end of his life. He took his London M.B., with honours in forensic medicine and obstetric medicine, in 1890; his B.S., again with honours, in 1891; the F.R.C.S. followed in 1892, and M.S. (gold medal) in 1894. He began steadily to build up a career as a surgeon and teacher of anatomy and surgery. In January, 1903, he was elected assistant surgeon at St. Bartholomew's, with special charge of the orthopaedic department, and full surgeon in 1912. He was lecturer on surgery and on clinical applied anatomy, and there are medical men in all parts of the world who owe much to his clear-cut method of teaching. His many years of work for St. Bartholomew's Hospital and College find occasional illustration in the *Hospital Reports*, of which he was for a long time joint editor. On leaving the active staff of St. Bartholomew's he was made consulting surgeon and a governor of the hospital. He also for many years served the West London Hospital as surgeon and was consulting surgeon to the City of London Truss Society.

His early surgical work, under the influence of John Langton, was on the hernias, and writings by him on this subject will be found in the *West London Medico-Chirurgical Journal* as early as 1898. In 1900 he published a book on *Hernia: its Aetiology, Symptoms, and Treatment*, which reached a third edition in 1908. It was also in 1900 that he gained the Jacksonian prize of the Royal College of Surgeons of England with an essay on the pathology, diagnosis, and treatment of diseases caused by, or connected with, imperfect descent of the testicle, and this appeared in book form three years later. In 1902-3 he was Hunterian professor of the College, and in 1904 an examiner in anatomy for the Fellowship. From 1924

until 1932 he served on the College Council and he was Arris and Gale lecturer at the College in 1930. At various times he examined in surgery for the Universities of Cambridge and of Glasgow and for the Society of Apothecaries. During the war of 1914-18 he was attached to the First London General Hospital and held the brevet rank of lieutenant-colonel, R.A.M.C. (T.F.).

The service which McAdam Eccles rendered to the British Medical Association was long and varied. He was a prominent member of the Warlebone Division and the Metropolitan Counties Branch Council, and he began to come into central affairs about 1913, when he was a representative. He was elected to the Council in 1919, and remained in unbroken membership for nearly a quarter of a century. A formidable amount of committee work began with his membership of the Hospitals Committee of which he was at one time chairman. To this committee he brought not only great experience but a real love of hospitals and a faith in the voluntary system. One put subject of his was provident schemes to ensure the provision of hospital service for middle-class persons. He was also a member of the council and for a time chairman of the United Kingdom Branch of the International Hospitals Association. This flower never bloomed very vigorously, but McAdam Eccles did succeed under its auspices in bringing to B.M.A. House at a meeting during the war the heads of three States—the King of Norway, the President of Czechoslovakia and the Grand Duchess of Luxembourg. From 1932 to 1940 he was a member of the Consultants Board and of the Consultants and Specialists Group Committee, and on two occasions he was vice president of the Section of Surgery.

His hand was felt in other Association activities, such as the admirable report on fractures, the work of a committee in 1933-5, in the special committee on physical education, and in another on workmen's compensation, a subject on which he had had experience in the courts and spoke with authority. He was also interested in the routine work of the Association and served at various times on the Organization, Finance, and Journal Committees. He was an active figure in the fight against the proposal to set up a register of osteopaths and although he did not give evidence, he was very much behind the scenes in the case which the Association presented to the Select Committee of the House of Lords on that subject in 1934-5. Another subject which never failed to interest him was guidance for senior medical students and newly qualified practitioners, and many will recall the crisp advice he gave year by year at the meetings arranged by the Metropolitan Counties Branch for those newly entering practice. For many years he represented the B.M.A. on the Central Council for the Care of Cripples and on other bodies. At the close of his active work for the Association it gave him enormous pleasure to be elected vice-president. He was also a member of the Association of Surgeons of Great Britain and Ireland and of the Anatomical Society, and had filled the chair at different times of the West London Medico-Chirurgical Society, the University of London Medical Graduates Society—of which he was one of the founders—and the Paget Club. He was chairman of the medical committee of the Scientific Film Association.

No obituary tribute would do justice to McAdam Eccles without a reference to his deep religious faith. In middle life he became a prominent layman in the Presbyterian Church of England and often occupied the pulpit, where he was always simple and earnest. He had a great love for foreign missions as those who have attended the medical missionary breakfasts at the Annual Meetings of the B.M.A. will know. He was also in evidence at the temperance breakfast and took every opportunity to put forward his strong convictions on the subject of total abstinence.

The picture that will remain with the present writer is of McAdam Eccles's work during the London "blitz" of 1940-1. He was in charge of the first aid casualty station at the Heart Hospital in Westmoreland Street. He made it a model station insisting on every piece of equipment being in its proper place and the staff of nurses and attendants trained "to the last ounce." During those evenings when the siren would go and the guns in Hyde Park make the whole building throb for hours McAdam Eccles would carry through the drill, see that everything was ready for possible casualties, and then, after a meal and before settling down for the night on some kind of

couch, he would enjoy a game of halma with a fellow-surgeon. He was a man of great serenity and cheerfulness, with a sense of fun, as those who went with the B.M.A. party to Melbourne in 1935 will recall. He could never resist an occasion for making a speech, but it was always concise and to the point.

McAdam Eccles had been a widower for many years. He had three sons, one of whom fell in the war of 1914-18. His son Mr. David McAdam Eccles has been Conservative M.P. for Chippenham since 1943, and married a daughter of the late Viscount Dawson of Penn.

DR WILLIAM GRIFFITH PRITCHARD died at his home at Llandudno on April 30. He was born at Penrth Llandwrog, Caernarvonshire in 1869, and received his early education at Menai Bridge, Anglesey, later going to St. Munco's College, Glasgow, and qualifying L.R.C.P., L.R.C.S.E.d., L.R.F.P.S. Glas. in 1896, winning the gold medal of his year in midwifery. After a brief period as an assistant in South Wales he settled down in practice at Bethesda, Caernarvonshire, for nearly 40 years, retiring in 1937 to reside in Llandudno although during the war years he repeatedly came out of his retirement to help overworked doctors in the area. Dr. Pritchard was a J.P. for the county of Caernarvon, a member of the standing joint police committee, and the chairman of the Conway and Llandudno juvenile court. In 1910 he was elected to the Bethesda urban district council and was its chairman in 1913-14 and 1924-5. He joined the B.M.A. in 1899 and was an active member of the North Caernarvonshire and Anglesey Division, becoming its chairman in 1922-3, and its representative on the North Wales Branch Council until his death. In professional life Dr. Pritchard's thoroughness and devotion to duty, combined with his great sympathy, endeared him to all his patients. He is survived by his wife and only child, a daughter.

The National Baby Welfare Council regrets to announce the death of Miss NORAH MARCH who for a number of years was secretary of the Council. Miss March not only devoted the greater part of her life but also sacrificed her health, to the cause of maternity and child welfare. She was for many years editor of *Mother and Child* and secretary of the Health and Cleanliness Council.

Universities and Colleges

UNIVERSITY OF LEEDS

Dr. Ronald Ernest Tunbridge, O.B.E., F.R.C.P., consulting physician to St. James's Hospital, Leeds, has been appointed to the newly instituted whole time chair of medicine in the University. After distinguished service with the R.A.M.C. in Malta he was appointed consultant physician to the 21st Army Group, B.L.A., with the rank of Brigadier. Prof. Tunbridge, a graduate of Leeds, has been tutor, and afterwards reader in medicine, in the University.

QUEEN'S UNIVERSITY OF BELFAST

The first Frederick W. Price Lecture was delivered by Dr. Gordon M. Holmes, F.R.S., in the Great Hall of the Queen's University of Belfast on Thursday, May 9. The Vice-Chancellor, Dr. Lindsay Keir, LL.D., presided, and there was a large audience of members of the medical profession and senior students. Dr. Keir welcomed Dr. Price and thanked him, on behalf of the University, for his generosity in establishing the lecture which bears his name. Dr. Gordon Holmes in the course of his inaugural address on "The Evolution of Clinical Medicine as Illustrated by the History of Epilepsy" recounted the history of epilepsy from very early times through the ages to the modern investigations by the electroencephalogram paying tribute to the work and observations of Hæthelred, Jælskors-Gövers, and others. Prof. W. W. D. Thom on proposed, and Prof. J. H. Bennett seconded, a vote of thanks to Dr. Holmes. Both speakers referred to the presence and generosity of Dr. Price to which he replied expressing his warm admiration for the University and the people of Ulster.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

DOBT.R.C.O.G.—Notice is given by the College that Regulation 3 relating to practitioners qualified over ten years has been reinstated. Applications may be considered forthwith under that Regulation.

Medical Notes in Parliament

HEALTH SERVICE BILL

On May 28, Mr. Bowles being again in the chair, the Standing Committee resumed consideration of Clause 7 (Endowments of voluntary hospitals). Mr. Bevan being absent through illness Mr. Key was in charge of the Bill. In subsection 2, which provides that endowments of voluntary hospitals designated as teaching hospitals should be held by the Board of Governors on trust for the purposes of the teaching hospital generally, Mr. Key proposed to insert: "Such purposes relating to hospital services or to the functions of the Board under this part of this Act with respect to research as the Board think fit." Mr. Key said this and an amendment which followed were to make clear the purposes to which endowments left to the teaching hospitals could be used. The Ministry felt that the original wording of the Clause might be interpreted as not extending powers to use the endowments for research. The two amendments made clear that a wide interpretation was to be placed upon the powers of the board of governors in using the endowments. The Committee agreed to the amendment and to a consequential one.

NON-TEACHING HOSPITALS' ENDOWMENTS

To secure a general discussion of the Government's policy about the endowments of non-teaching hospitals Sir H. LUCAS-TOOTH moved to leave out subsection 5 of Clause 7, which provides for the making of regulations "for the control and management of the hospital endowments fund." He said until Parliament saw these regulations they could not know what proposal was in the Minister's mind. There should be an express enactment to deal with the fund. Precise proposals for dealing with the endowments should be incorporated in the Bill. The endowments of teaching hospitals appeared to be considered as "pocket money" and the governors of these hospitals could apply the capital and the income of their endowments to purposes over and above what was received from the State for general maintenance. In the case of the non-teaching hospitals this was not clear, and he asked Mr. Key to define the purposes for which capital and income could be put by these hospitals. Mr. H. STRAUSS said there ought to be a provision binding the Minister in regard to the charitable trusts which he took over. Lord WILLOUGHBY DE ERESBY said one of the dangers arising from the centralized control of money was that hospitals were not allowed to make local purchases.

Mr. Key replied that Regional Boards and Management Committees were to submit annual estimates, and within the sums approved they would have great freedom of expenditure. The Ministry would not take away their responsibility for making necessary purchases, but the last thing the Ministry desired was that endowments should be used to buy fruit and food for patients. The general maintenance of hospitals and buildings was not to fall upon the endowments fund, but upon the general exchequer as part of the business of the control boards. With regard to the regulations which would govern the use of endowments, or any alterations in the regulations concerning the future use of endowments, these regulations would be subject to the negative resolution procedure in Parliament. They could not be amended, but they could be thrown out. In apportioning the fund the Minister had to take into account the conditions of the region—the number of existing institutions and beds must be a guide, as also the need for development in the area of hospitals services for which the Ministry would be responsible out of national funds. Liabilities attached to the fund, such as an accumulated building fund, which was to be treated as an endowment, must be retained as a building fund. It was the duty of the Minister and of the Regional Boards to see to the maintenance of the institutions that were required. That charge would not be met out of the endowment fund but out of the general exchequer.

RELIEF FOR THE TREASURY

Mr. LINSTEAD said the complications of the Clause arose from the fact that it was an artificial arrangement. What the Minister was doing was to confiscate all the endowments of the voluntary hospitals and then to dress up the transaction in the form of a hospital endowments fund. In fact these endowments were going in relief of Treasury expenditure. Mr. Linstead asked whether endowments which would be given in future to hospitals would be held directly by the Management Committees or by the Regional Boards for those committees.

Replying to Col. Stoddart-Scott Mr. KEY said that when the local authority hospitals were taken over their liabilities would be met out of national funds and would not be a debt on endowments, nor would they be brought into consideration in the distribution of endowments. Nor in the normal way were the ordinary liabilities for the maintenance of voluntary hospitals to be met out of endowments. As the Bill stood the power of holding endowments lay only with the Regional Board. It was the Minister's intention to extend that power to Management Committees, and before the Report stage the Minister would take the necessary steps to see that this power was vested in the hospital Management Committees.

The proposed amendment was rejected by 28 to 13. The Committee then agreed to an amendment proposed by Mr. Key enabling the Minister to meet out of the endowment fund liabilities which would be transferred to him under a new subsection to be moved later. [That subsection provides that the rights and liabilities in the endowments—such as contracts for repair and maintenance, supply of goods, liabilities from the holding of securities, etc.—shall be transferred in the same way as the endowments.]

Mr. LINSTEAD moved an amendment to place the Regional Boards under an obligation to put back into individual hospitals some of the endowment income they received from those hospitals. Mr. KEY replied that this was the intention of the Government and that an amendment would be put down on the Report stage to secure that this was done. Mr. Linstead withdrew his amendment and the Committee agreed to an amendment proposed by Mr. Key permitting the Minister to make regulations on the functions of the Board under Part II of the Bill with respect to research. He said this was intended to give the Regional Boards the freedom with regard to the use of endowments which had previously been extended to the boards of governors of teaching hospitals.

The Committee here accepted the new subsection, referred to above, on the transfer of liabilities.

POSITION OF COVENANTS

In subsection 8 of Clause 7, defining the expression "endowment" in relation to a voluntary hospital, Mr. KEY moved to substitute a new and longer definition of the property concerned. He said the amendment, as drafted, covered all real property—such as houses, farm lands, furniture, equipment, and other movable property used in connexion with it—securities and other personal property held as investments, cash, bank credits, cheques, and so on, and finally annual payments under covenant for the benefit of the hospital. If on the appointed day the hospital showed a credit balance that balance had to be treated as an endowment and not transferred to the Minister. Debts owing to a hospital would fall to be collected by the boards of governors or by the Regional Boards. The second part of the amendment was designed to extend to local authorities the same sort of provision, because there were trust funds even in connexion with local authority hospitals. Such property should go to the board of governors or to the Regional Boards.

Mr. H. STRAUSS expressed astonishment at the proposal that the Minister should enforce for his own benefit the seven-year covenants into which covenanters entered for the benefit of specific hospitals. In supporting this protest several members disclosed that they had themselves entered into such covenants.

Mr. KEY said the endowments funds with which the Committee were dealing were not for normal maintenance of the hospitals service. They were to be used for charitable purposes by the Regional Boards and the hospital Management Committees. To say that these covenants should pass to the endowment fund was to find for them the nearest possible destination to fulfil the purposes for which they were provided. If other hospitals or other charities were beneficiaries interested in trust property the property would continue to be administered by the trustees. The expression "endowments" in the definition he had just moved covered only property in which a particular hospital was the sole beneficiary.

The words proposed by Mr. Key were added to the Clause by 28 to 14, and Clause 7 as amended was added to the Bill by 27 to 14.

MEDICAL SCHOOLS

On Clause 8 (Exception for medical and dental schools) Mr. KEY moved that in the case of the Welsh National School of Medicine all properties and liability held or incurred for the purpose of the school, not being already vested in bodies specifically mentioned in the Clause, should be transferred to the governing body of that school. Normally a medical school was part of a university and did not of itself own property or incur liabilities, but the Welsh National School was a separate entity. The Committee agreed to the amendment, and to one excepting the University of London and the University of Wales from transfer of schools' property "to the governing

body of the university of which the school is a part." It also accepted a new subsection, proposed by Mr. Key, that if any institute for the postgraduate teaching of medicine or dentistry, being associated with any hospital to which Section 6 of the Act applied, was recognized by the Minister before the appointed day, Clause 8 should apply to it, and all property or liabilities held for the purposes of such an institute should, on the appointed day, vest in the governing body of the institute. Dr. MORGAN said the property of medical schools should be associated if possible with the hospital to which the school was attached, but sometimes vital buildings and equipment belonged to the school that should belong to the hospital. Mr. KEY replied that property partly for school and partly for hospital purposes would be apportioned by regulations under Clause 6.

Clause 8 as amended was ordered to stand part of the Bill and the Committee adjourned.

WAR DAMAGED AND PROPOSED NEW HOSPITALS

When proceedings were resumed on May 29 Mr. Key was again in charge of the Bill. On Clause 9 (Supplementary provisions relating to transfer of hospital property and liabilities) Mr. KEY moved to add four new subsections dealing with premises intended to be used for the purposes of a hospital when adaptation had begun, land on which hospital building or works were to be constructed, and where construction had begun before the appointed day, and also premises used for hospital purposes but destroyed or damaged and not restored before the appointed day. Mr. KEY said the Bill as it stood was really only apt where premises were substantially capable of being used for hospital purposes and were actually in being. The proposed subsections would cover all cases where existing or new buildings were going to be restored or used for hospital purposes. Where, however, a building had been acquired for adaptation, or a site for a new building and no work or adaptation had been begun, then the property would be treated as an endowment and not as hospital premises. His amendment also dealt with local authorities' premises temporarily in use for hospital purposes but not intended to be used permanently for such purposes; these premises would be made hospital premises for the purpose of transfer. Under the War Damage Act, 1943, the rights of war damage payment for hospital buildings would vest in the governing bodies and the local authorities which were their previous owners. One new subsection transferred the rights to boards of governors of teaching hospitals, and to the Minister in all other cases. Where, however, damaged property was an endowment property a proviso to the subsection made the right to a value payment into an endowment under the Bill.

Mr. SOMERVILLE HASTINGS moved an amendment which provided that where the local authority before the appointed day incurred expenditure in making war damage good, it should be reimbursed that amount out of the payment to the Ministry for war damage. Mr. KEY agreed in principle with the intention but said the amendment was not satisfactory as drafted, he undertook to prepare an amendment before the Report stage which would satisfy the principle. Mr. Hastings withdrew his amendment, and the subsections proposed by Mr. KEY were then added to Clause 9.

Col. GAGE moved an amendment to ensure that regulations made by the Minister under this Clause were such as would logically follow on the provisions of the Bill. He suggested that the empowering words in the Bill were too wide and would, for example, allow the Minister to make regulations taking over and running for profit the shops which had been mentioned as being architecturally a part of St. Mary's Hospital. Mr. KEY said there was no such sinister intention, but provision had to be made to meet circumstances not now predictable. If unreasonable and improper regulations were made the remedy lay with Parliament. The amendment was defeated by 24 to 13.

Mr. MESSER moved to leave out a provision that the Minister may make regulations for amendment of documents relating to any transfer of property or liabilities. Mr. KEY said this power was needed and had always been given when property was transferred by statute. It had been given in the Ministry of Health Act, 1919. Mr. Messer withdrew his amendment.

On Clause 10 (Power to acquire hospital equipment) Mr. LINSTAD moved to add a proviso that if the Minister compulsorily acquired part of the equipment, furniture, or other movable property of any hospital, the owner thereof could require him to take over the whole or any part of the remainder. Mr. Linstead said that what were called "tenants' fixtures" were to be at the disposal of the Minister for acquisition under this Clause; he might take the cream off the milk and leave the tenants with valueless material once it was removed from the premises. Mr. KEY said he could not accept the amendment, which would compel the Minister to take over

things he did not want. Sir H. MORRIS-JONES thought this was one of the most reasonable amendments put before the Committee. Mr. KEY said the suggestion was that the Ministry should spend public money in acquiring something of no value. That was not the standard of public administration which it wished to see in operation in this country. Mr. SOMERVILLE HASTINGS said that when in 1930 the L.C.C. took over a number of hospitals from the Boards of Guardians there was little equipment worth having, and for 10 years the L.C.C. had difficulty in getting rid of obsolete material. Dr. MORGAN said some private mental institutions had not changed equipment, etc., for 40 years; it was extraordinary to suggest that the Minister should have no regard to the modernity of the equipment. In one private mental hospital he knew plans were being made to fill the place with old furniture so that the Minister might take it over.

The proposed amendment was rejected by 24 to 15 and Clause 10 was ordered to stand part of the Bill.

AREAS OF REGIONAL BOARDS

On Clause 11 (Regional Hospital Boards, Hospital Management Committees, and boards of governors of teaching hospitals) Mr. WILLINK moved that orders made by the Minister constituting such authorities should be made "after consultation with the Central Council." He said the opening words of Clause 11 were obscure. There was reference to determination by the Minister and to orders by the Minister, who was to constitute Boards for such areas as he might determine. He (Mr. Willink) was not sure whether the determination was going to be in the order. His proposal was that the Minister's order could be made only after consultation with the Central Council. The vital question was the character and size of the regions. In the Bill those counties which cut across part of the catchment areas of the hospitals were themselves set up as clinic authorities, and those clinics must be run in the closest co-ordination with the hospital services. The Central Council ought to advise and be consulted on the constitution and determination of a region. Mr. BEVAN might decide that there were to be 16 or 20 regions as indicated in the White Paper, 10 or 11 as indicated by those whom Mr. Willink called "the pundits," or 25 to 35 which he, in common with many others, had aimed at a year ago. As the Bill stood the number was entirely uncontrolled. The Committee did not know whether the Minister was going to treat the problem of the London region as a matter for his personal decision without consulting the Central Council. Mr. BEVAN should undertake an obligation in the Bill so that Parliament could discuss the orders setting up the Regional Boards and to ensure that he could consult the Central Council on this vital matter.

Mr. KEY replied that orders setting up the Regional Boards would have to specify the areas for which they were being constituted. That was necessary because the regions would have to be subject to alteration by amending orders in the light of experience. In setting up Regional Boards one aspect of the problem would be delimitation of the areas for a specific Regional Board. There was also the question of the constitution of the particular board, and, thirdly, the selection of individuals to be appointed. These last two subjects were not matters for consultation between the Minister and his Central Council. Mr. KEY believed, however, that in delimiting the areas of the regions the Minister would have to consult the Central Council and take advice. He thought that would be the intention of the Minister, but it would be dangerous to insert in the Bill the words proposed by Mr. Willink. Mr. Willink's amendment was negative.

Mr. RICHARD LAW moved to substitute "regulation" for "order" in the provision authorizing the Minister to constitute Regional Hospital Boards; the amendment would mean that the Minister's scheme setting up the Regional Boards and defining the regional areas would have to be submitted to Parliament. Mr. KEY said he was advised that the appropriate instrument for constituting such bodies was an order. After discussion the amendment was withdrawn.

Mr. MESSER moved to insert the words "by order" in the reference to the determination of areas by the Minister. He said there was no provision in the Bill for consultation with the local authorities, who were much concerned in these decisions. If a region was so determined that it cut through more than one local health authority that local health authority had to consult more than one region and that region more than one local authority. There was need, as the Bill did not provide for any consultation, that Parliament should have the opportunity of reviewing the order. Mr. KEY said that Mr. BEVAN regarded this as an administrative function to be decided by him administratively, and he must have the necessary power to settle these areas and to modify them. Mr. BEVAN had said earlier in the Committee that he would do this only after

consultation with local authorities, medical practitioners, and hospital authorities, but the determination must lie with the Minister. Mr. Key was ready to agree that the Ministry could modify the working of the Clause to ensure that the areas would be specified in the order constituting the original Board.

Mr. Messer's amendment was defeated by 20 to 17 and the Committee adjourned.

DAY-TO-DAY ADMINISTRATION

The ninth day's proceedings began with a motion by Mr. Lipson to omit in subsection 1 of Clause 11 the word "administration" and to substitute "planning, co-ordination, and general supervision." The term "administration" was far too indefinite. The Regional Boards would not manage the hospitals; it would be their function to see that the provision of the services for implementing the proposals for a National Health Service were satisfactory. Sir H. WEBB said the amendment removed from the Regional Boards responsibility for administration of the hospitals. Subject to anything that might be provided later in the Bill it would throw back administration to those authorities who now exercised it. In the case of local authority hospitals that would be a fundamental improvement and would remove the greatest objection to the scheme. If the Bill went forward as it stood administration would be taken from the health authorities who now exercised it, and handed over to a new body, with the result that the position would be worse than before 1930, when local authorities were concerned solely with the preventive medicine side of public health. An area embracing London and the Home Counties was too big as an administrative unit though possible as a planning unit. If the Regional Boards were to administer, London would be faced with the sector administration adopted during the war. That would not work. Half a dozen hospital areas might meet in London, and the L.C.C., as the one health authority responsible for all the domiciliary health services, would work upwards to a number of hospital authorities. Teaching hospitals were not evenly spaced through London. Unless these regions were drawn with boundaries which would make a Chinese puzzle, some of them would each have one teaching hospital at their disposal while others would have an embarrassment of choice. Most of the mental hospitals which served the Greater London authority were in the triangle bounded by Epsom, Redhill, and Croydon. In other stretches of the periphery there were no mental hospitals. Therefore anything in the nature of regions radiating from the centre would produce an impossible position. All these difficulties would disappear if the Minister accepted the point that while the planning and co-ordination of services was a function of the Regional Board, administration of the hospitals remained a function of the local authorities. It was clever of the Minister to use the well-known reluctance of the medical profession to have anything to do with the local authorities; that was why the Committee must be prepared to leave the administration of voluntary hospitals to be dealt with differently. He could see no reason why there should not be a planned scheme of hospital service, planned by the region under the Minister's supervision and administered by existing authorities—by, if the Committee agreed, the present governors of the voluntary hospitals.

Mr. KEY said the amendment would break up the whole administrative side of the Bill. What the Committee was doing was to bring about the organization not of a local hospital service but of a national hospital service. It was undertaking the responsibility of seeing that everybody, no matter in what area he lived, had an efficient service. Responsibility for that service was placed upon the Minister, and the Bill proposed that he should work through Regional Boards, which in turn would work through hospital Management Committees. The efficiency of that administrative scheme would be vitiated if the Regional Boards were mere planning and supervising authorities. The threat of withholding money was not an efficient instrument for getting proper administration. Hospital Management Committees would not be responsible for a local authority area; they would manage an institution or a group of institutions related functionally and not merely geographically. Therefore local autonomy was not the conception of this scheme.

MINISTER'S CHANGE OF MIND?

Mr. WILLINK said Conservatives would vote in favour of the amendment though not committing themselves to its terms, which were too vague. The reply they had just heard from Mr. Key showed that when the decision to nationalize was taken the Minister did not know what he was doing, and that he was still changing his mind as to how he was to perform his functions. The Opposition did not believe that Regional Boards ought to be administrative bodies. These Boards could not administer a hospital unless they administered it from day to day. Hospital Management Committees would be devised

as purely functionary units. He thought that disastrous. He asked why the Minister sought to retain the original language of the Bill when his conception of the Regional Board had changed, and he was increasing the functions of the hospital Management Committees. Mr. Willink thought the Minister meant that the Regional Boards were compulsorily to delegate administrative responsibility and to retain supervision. He would be satisfied if the Minister would change Clause 11 to bring the conception of administration into the work of the hospital Management Committees.

Mr. HOPKIN MORRIS said the Regional Boards should be given powers of planning and co-ordination but not day-to-day administration, because that would result in a Regional Board for the whole of Wales interfering with the day-to-day management of the medical school at Cardiff. Mr. LINSTED asked the Committee to look at the question from the point of view of hospital staffs. Nursing staffs were jealous that they were members of the staff of a particular hospital and were now apprehensive that they were to become members of the staff of a region. Mr. LIPSON asked whether Mr. Key could reconsider the matter before the Report stage to prevent the Regional Board being cluttered up with details of day-to-day administration.

Mr. KEY said "administration" in this context referred to the general administration of the service. The function of the hospital Management Committee was to administer the detailed day-to-day business of a hospital or group of hospitals. There had been no changes in the conception of this scheme of administration. The possible exception was the Minister's decision to see that hospital Management Committees received powers to hold trusts and accept gifts. The Government's conception was that the hospital Management Committee would choose and appoint the ordinary staff of the hospital group. Responsibility for payment would rest with the Regional Board. Appointment, selection, and dismissal of ordinary staff would remain with the Management Committee, whose business it would be to maintain and supply their hospitals. Any major alteration to a hospital would rest with the Regional Board, but the day-to-day maintenance would be conducted by the Management Committee. Patients and other local people would be in contact with the Management Committee. Mr. Bevan held firmly that for efficient planning, supervision, and control there must be this chain of responsibility from him through the Regional Board to the hospital Management Committee. So far as possible detailed responsibilities would be passed on to the lower bodies.

The amendment proposed by Mr. Lipson was rejected by 25 to 16.

Mr. MESSER, on the same subsection, moved that the Minister before making any order determining an area should consult the local authorities providing health services or such other organizations as appeared to him to be concerned. He wanted to prevent confusion resulting from a regional boundary line cutting across the boundaries of local authorities. Mr. KEY said the Ministry agreed that there should be these consultations, but he could not accept the amendment because words prescribing consultations with one interest would exclude people whom it might be necessary to consult. Mr. Messer withdrew his amendment.

HOSPITAL VERSUS GEOGRAPHICAL UNIT

Cmdr. MAITLAND moved to insert a provision in subsection 3 of Clause 11. This subsection authorizes the Minister to approve, with or without modifications, additions, or exceptions, any scheme submitted by a Regional Board, and imposes on the Board the duty of giving effect to the scheme as approved. Cmdr. Maitland's amendment proposed that before approving such a scheme the Minister should be satisfied that a hospital Management Committee did not exercise functions unless the hospitals forming its group were within the same locality and were in any event within the area of the same local health authority. The purpose of the amendment (which mainly concerned rural areas) was to relate the number of beds in the area controlled by the Management Committee to the size of the area and the geography of the district.

Dr. STEPHEN TAYLOR said Cmdr. Maitland was making a case for the grouping together of a few small cottage hospitals because they might be geographically or socially linked. It was essential for an efficient hospital service that the number of cases of a particular kind in an area should be adequate to maintain specialists. The danger of having small units of hospital administration was that the nation got small hospitals where the general practitioner performed specialists' work. An abuse described as bogus lists of consultants had grown up in cottage hospitals. These consultants did not attend. Mr. WILLINK pointed out that specialists were not employed by the Management Committee. The specialist of a region

could be attached to three, four, or five hospital Management Committees. The scheme fastened upon the country a system whereby no hospital Management Committee could have fewer than 1,000 beds or thereabouts. He thought Mr. Bevan, during the few months he had been at the Ministry, had encountered an idea that gynaecologists and obstetricians did not get enough important cases unless there were maternity units of at least 100 beds. To get that result a hospital had to draw from an enormous area.

Dr. TAYLOR said that when Mr. Willink was Minister of Health he, Dr. Taylor, had consultations with the Ministry on the proper proportion of hospital beds to population. The figures arrived at was between 8 and 10 per 1,000. These need not be in one place, but they would be put under one Management Committee. Mr. WILLINK said that was not the ratio this country would have for many years to come. If this Bill was to be safeguarded from one of its greatest dangers—the absence of tie-up between clinic service and hospital service—the Minister should favour a geographical county as the appropriate area for a Management Committee.

Mr. KEY said there was no intention that the Minister should be hidebound by any idea of 800, 1,000, or 1,200 beds. He could not agree that the area must in any event be within the area of the same local health authority. Nor could he agree that the Ministry must not include a hospital establishment that was just outside the bounds of an ordinary county borough. Cmdr. Maitland withdrew his amendment.

On the motion that the Clause stand part of the Bill, Mr. LAW drew attention to subsection 7 of Clause 11 empowering the Minister to designate as a teaching hospital other hospitals than the existing teaching hospitals. He asked whether the Minister intended to consult not only the university concerned but also the Central Council. Sir H. LUCAS-TOOTH asked whether the Minister had considered sufficiently the transition from the old to the new organization. In Middlesex the numbers engaged in lay administration—including engineers, architects, legal experts—ran into hundreds. Most of these were employed by the county council for general purposes and did their work in connexion with hospitals among their other work. To use the existing organization in taking over would be possible only if the new regional area coincided with the county council area. Mr. KEY said the Ministry would consult with local authorities and others about the problems of transition. The designation of additional teaching hospitals was a matter for the universities and not for the Central Council. If it was felt in consultation with the universities that the advice of the Central Council would be helpful the Minister would take the necessary steps.

Consultants' Terms of Service

On May 23 Mr. BESWICK asked when the Minister of Health intended to make a statement as to the financial terms to be offered consultants under the proposed new National Health Service. Mr. BEVAN replied that this would be a matter for discussion with the profession when Parliament had settled the general structure of the new service.

Health Service Films?

Mr. SOMERVILLE HASTINGS asked Mr. Bevan on May 23 to arrange for the preparation of films to explain to the public the health service that would be developed under the Bill now before Parliament. Mr. BEVAN said he would certainly consider this as soon as Parliament decided upon the shape of the new service.

E.M.S. Hospitals

Dr. SEGAL on May 23 asked whether Mr. BEVAN would give an assurance to existing E.M.S. hospitals that they would continue to be retained until such time as a co-ordinated hospital policy could be carried out. Mr. BEVAN answered that as the commitments of the Emergency Hospital Scheme contracted, the scheme itself must contract; he could not, therefore, give this assurance. No emergency hospitals were given up without first considering the probable future needs of the hospitals services. He had no Parliamentary authority to provide hospitals, except for patients intended to be treated by the Emergency Hospital Service. Until it received new powers the Ministry of Health could not own hospitals and could not make available to people hospital facilities which Parliament had not provided.

N.H.I. Assets

Mr. James Griffiths was asked by Sir E. GRAHAM-LITTLE on May 17 to give the present disposition of the assets of the Health Insurance system, which at the end of 1944 amounted to £250,000,000. Mr. GRIFFITHS replied that about £60,000,000 of these assets was held by approved societies and the balance

by the National Debt Commissioners. He said that in the main these assets were not a surplus. They represented the actuarial reserves in respect of existing insured persons.

Gastro-enteritis in Leeds School-children

Mr. STAMFORD on May 23 asked Miss Ellen Wilkinson whether the investigations of the schools medical section of her department into the recent outbreak of gastro-enteritis among a large number of children attending schools in West Leeds had been completed. Miss WILKINSON said she had received an interim report from one of her medical officers which showed that the outbreak affected some 260 children from 14 schools in Leeds served by one central kitchen. The investigation, which was being conducted by the local authority, was not completed and the cause of the outbreak, which, though widespread, did not appear to have been serious, had not been determined.

X-ray Examination of Ire Ore Miners.—Mr. Shinwell is informed that iron ore miners seeking employment at coal mines in Cumberland may, in future, be required to undergo an x-ray examination under arrangements made privately by the owners. The cost of the examination will be borne by the owners and not by the men themselves.

Asitley Ainsley Hospital.—The Asitley Ainsley Hospital Order Confirmation Bill was introduced in the House of Commons on May 21 and was read a third time on May 23. The Bill proposes to allow the Governors to develop the occupational therapy department of the hospital and associated institution for treatment of patients of or from the Royal Infirmary of Edinburgh; also to admit students to the training centre at the institution, provide teaching staff, and issue diplomas.

Notes in Brief

In 1945 78 inmates of H.M. prisons were certified insane, compared with 65 in 1944 and 69 in 1943. In most prisons there is only one medical officer, and the certificate is ordinarily signed by him and by a doctor called in from outside the prison.

Mr. Wilmot has arranged for increased supplies of hypodermic syringes to be made available. Production has been stepped up and the position should improve rapidly.

Manufacture and distribution of vaccine lymph will in future be undertaken on behalf of the Ministry of Health by the Lister Institute of Preventive Medicine.

Local authorities are being advised in laying out their housing estates to leave space for houses each large enough to be used as a doctor's house and surgery. Mr. Bevan says these can be built when materials and labour are more plentiful.

Mr. Bevan has under consideration the question of making Regulations requiring the heat-treatment of ice-cream mixes before they are frozen.

Medical News

The Cavendish Lecture will be delivered before the West London Medico-Chirurgical Society by Sir Lionel Whitchy at Kensington Town Hall on Tuesday, June 18, at 8.30 p.m. His subject is "The Magic Bullet and After." Reception (morning dress) from 8 p.m. The annual conversation and medical and surgical exhibition will not be held this year. Invitation cards for members and their friends are being distributed. Any member who has not received a card should apply immediately to the secretary of the society.

The British Psycho-Analytical Society invites all members of the medical profession to attend the first of a series of annual "Ernest Jones" lectures entitled "The Physical and Mental Sources of Behaviour," which will be given by permission of the Royal Society of Medicine in the Barnes Hall at 1, Wimpole Street, W., on Wednesday, June 19, at 8.0 p.m., by Prof. E. D. Adrian.

An exhibition arranged by the London Council of Social Service to show how community centres may be planned, established, managed, and financed is now on view in Room 129 of County Hall (entrance in York Road, S.E.). It was opened by the Minister of Town and Country Planning on June 4 and will remain open till June 15, from 10 a.m. to 5 p.m., Thursday 10 to 4. It will be closed on Whit-Saturday, Sunday, and Monday. Admission is free.

The Scottish Council for Health Education is arranging three residential summer schools at St. Andrews University from June 29 to July 12 and August 3 to 17, and at Edinburgh from July 13 to 27. The courses will cover physiology, psychology, and social medicine, and speakers will include Col. Walter Elliot, Prof. F. A. E. Crew, Prof. Noah Morris, and Dr. Innes Pearce. The Avenue school at St. Andrews is fully booked, but there are still a few vacancies for the one from June 29 to July 12, and also for that at Edinburgh. Applications for enrolment should be addressed to the secretary, 3, Castle Street, Edinburgh 2.

The Maudsley Hospital Medical School is now holding Part I of its thirtieth course of instruction for a Diploma in Psychological Medicine; it began on June 3. Part II will be held from September to November. Information about the course may be had from Dr. W. W. Kay, acting hon. director, Maudsley Hospital Medical School, Denmark Hill, London, S.E.5. (Tel.: Rodney 2634-7.)

Sir Howard Florey, F.R.S., professor of pathology at Oxford, is leaving for South America on June 18 to lecture for the British Council to both lay and medical audiences on penicillin, and to doctors only on the uses of micro-organisms for therapeutic purposes. The lectures will be given in Spanish, except in Brazil, and will be illustrated by films and slides. Sir Howard will visit Argentina, Brazil, Chile, Colombia, Mexico, Peru, and Uruguay, spending about a week in each country. He will travel home via the United States and Canada.

Dr. William H. Feldman, of the Mayo Foundation University of Minnesota, Rochester, U.S.A., has accepted the invitation of the Council of the Royal Institute of Public Health and Hygiene to be appointed Harben Lecturer for 1946. The subject is the chemotherapy of tuberculosis—including the use of streptomycin. The lectures will be delivered at the Institute, 28, Portland Place, London, W.1, at 3 p.m., on Monday, Tuesday, and Wednesday, July 15, 16, and 17. Admission is free, without ticket; seats may be reserved on application to the secretary.

At a general meeting of the Society of Medical Officers of Health Sir Allen Daley, M.D., F.R.C.P., Medical Officer of Health and School Medical Officer, London County Council, was unanimously elected to be President for the session 1946-7, beginning on Oct. 1. At the same meeting the Honorary Fellowship of the Society for persons "eminently distinguished in the advancement of public health" was conferred upon Sir George Elliston, M.C., M.A., founder and editor of the *Medical Officer* since 1908—one-time executive Secretary of the Society; M.P. for Blackburn 1931-45, and now chairman of the Public Health Committee of the City of London, and of the Board of Management of the London School of Hygiene and Tropical Medicine.

Prof. Charlotte Ruys, a bacteriologist on the staff of the Netherlands Tropical Institute, made a short visit to this country during the early part of May under the auspices of the British Council to renew professional contacts. She visited the Central Public Health Laboratory, the London Hospital, the School of Hygiene, and the Wellcome Research Institution.

The order of the White Lion of Czechoslovakia has been conferred upon Mr. Geoffrey Knight by President Benes in recognition of his services as neurological surgeon to the Forces of the Republic.

Dr. H. E. Martin, honorary secretary of the Blackpool Medical and Panel Committee, and a temporary principal medical officer of the Ministry of Pensions, has been awarded the Haldane Prize of the Institute of Public Administration for an essay on "The Transition to a State Medical Service."

The freedom of South Queensferry has been conferred on Dr. G. A. Dickson in recognition of his faithful services to the community for nearly 50 years. Dr. Dickson was chairman of the Lothian Division of the British Medical Association in 1923-5.

EPIDEMIOLOGICAL NOTES

Discussion of Table

England and Wales recorded increases in whooping-cough 126, scarlet fever 90, and measles 88.

The increase in whooping-cough was due to a few areas: Yorkshire North Riding 37, London 28, Yorkshire West Riding 23. The only variation of any size in the trends of scarlet fever was an increase of 20 in Lancashire. Cases of measles increased in Essex 50, Durham 46, and Lancashire 44; a large fall was recorded in London 92.

Notifications of dysentery were 17 fewer than in the preceding week, and the total was the smallest for 24 years. The only large returns for dysentery were Lancashire 21, London 19, Middlesex 10.

Scotland reported a further decrease in the incidence of measles 184. Scarlet fever increased by 27 and diphtheria by 23. Rises in the incidence of dysentery were recorded in Glasgow from 15 to 28 and in Edinburgh from 6 to 13. The increase in diphtheria was mainly contributed by Glasgow, where the notifications rose from 31 to 47.

Eire had only one change of any size in the returns of infectious diseases—an increase of 20 in diphtheria. This was due to the experience of Dublin C.B., where the cases rose from 8 to 23.

Week Ending May 25

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,089, whooping-cough 2,075, diphtheria 371, measles 3,287, acute pneumonia 557, cerebrospinal fever 67, acute poliomyelitis 9, dysentery 200, smallpox 8, typhoid 8.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 18.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each Infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

ANY QUESTIONS?

Examination of a Virgin

Q.—Should vaginal examination of a virgin always be carried out under general anaesthesia? What would the legal position be if a female patient were examined *per vaginam* without being told of the examiner's intentions?

A.—Vaginal examination of a virgin should be avoided if possible; the information sought can usually be obtained almost, if not quite, as well by rectal examination. If, preferably after consultation, it is considered essential to make an examination *per vaginam*, the necessity for a general anaesthetic must be decided by the likelihood of the patient's reacting, mentally or physically, in a manner which would be unsatisfactory from the point of view either of the patient herself or of the examiner. While this is a matter to be assessed with reference to each particular case, the likelihood is sufficiently great to warrant a general opinion that vaginal examination of a virgin should be carried out under general anaesthesia.

The patient should be informed of the examiner's intentions, and in the case of girls and young women the mother or guardian should be similarly informed. In the case of Service patients the girl's senior officer should be regarded as being *in loco parentis*. If the patient were not informed of the examiner's intentions an action for assault might be raised. Though such an action could have little chance of success if the examination were shown to be medically justifiable, it is an eventuality which should not be risked.

Demonstrating *Treponema balanitis*

Q.—How is *Treponema balanitis* demonstrated? It is not mentioned in the new edition of two standard books on bacteriology.

A.—*Treponema* (or *Spirochaeta*) *balanitis* is best demonstrated by dark-ground microscopy; staining is unsatisfactory, since fixation of the organism does away with its two most characteristic features—shape and movements. A short description of the organism and the clinical condition to which it gives rise may be found in several textbooks on venereal diseases, including those by Harrison, Lees, Burke, and McLachlan.

Breathing Exercises for Emphysema

Q.—Are breathing exercises of any use in emphysema? If so, what kind of exercises should be advised?

A.—Breathing exercises may be prescribed with two different objects in view. Exercises of the inspiratory type are used in emphysema to encourage re-expansion of the lung and to limit contraction of the chest wall. Exercises designed to increase expiratory power, and especially the movement of the diaphragm, are employed in the treatment of asthma and emphysema. The benefit to be derived from breathing exercises in emphysema depends upon an increase in the patient's ability to overcome the tendency to fixation of the chest wall in the inspiratory position, and in the freedom of movement of the diaphragm, which also tends to be held fixed in the inspiratory position. The breathing exercises described in *Physical Exercises for Asthma*, published by the Asthma Research Council, are suitable for emphysematous patients.

Occult Blood

Q.—Should the patient be on a meat-free diet for three days before testing faeces for occult blood? Most specimens of faeces from patients on a meat diet give a negative test.

A.—The statement in this question is true only if a comparatively insensitive test for occult blood is used. Even the benzidine test may be reduced in sensitiveness by technical variations or errors, such as failure to prepare a fully saturated solution of benzidine in acetic acid. In order to ensure the detection of minor degrees of haemorrhage it is desirable that the test should be a sensitive one; it is then essential, if false positives are to be avoided, that the patient should have a meat-free diet beforehand.

Nystagmus in an Infant

Q.—A 2-months-old child had a concomitant squint, which had been present at, or shortly after, birth. There was also a very fine, rapid, incessant rhythmic oscillation of both eyes, rather like the motion of the balance wheel of a watch. Now, at the age of 16 months, the squint has slightly improved and the oscillations have almost gone. The child is normal in every other respect. (a) What is likely to have been the cause of the oscillation? (b) As the mother would prefer the child not to wear glasses, is any other treatment suitable? (c) If operation is necessary, at what age is it best performed?

A.—(a) The nystagmus may be amblyopic, hereditary, or idiopathic. The causes of an ablyopic nystagmus are: opacities of the cornea—especially in ophthalmia neonatorum—congenital cataract, haemorrhage, disease or abnormalities of the retina and choroid, total colour blindness, and albinism. (b) It is hardly practicable for a child of under 2 years to wear glasses. Later, if there is a refractive error necessitating correction, glasses should be insisted on—there is no adequate substitute. (c) Supposing the eye is healthy, unless the squint is very marked operation should be delayed until the child has had orthoptic exercises. These can usually be started at the age of 4 years. In the meantime the fixing eye should be atropinized with 1% ointment once a day to prevent the non-fixing eye from becoming amblyopic.

S for Sugar

Q.—What do the letters W at 1000, H at 1016, and S at 1026 stand for on the urinometer?

A.—W stands for water. H stands for healthy, 1016 being the approximately normal specific gravity of urine in a healthy individual. S stands for sugar, as it is above the specific gravity of 1026 that one would expect to find sugar in the urine.

Athlete's Foot

Q.—Is iodized phenol used in the treatment of athlete's foot?

A.—Iodized phenol can be used for athlete's foot, but it is not recommended as it may cause irritation. In spite of the many new forms of treatment introduced from time to time, Whitfield's ointment and Castellani's fuchsin paint still maintain their reputation.

Recurrent Vulval Herpes

Q.—A lady aged 71 has had recurrent attacks of herpes on the vulva and buttocks since the age of 46. She had twenty or twenty-five attacks a year until she had sprue two years ago. She now has thirty to forty attacks. Oestrogens, injection of calf lymph, x rays, and autohaemotherapy have been tried. Is there any other treatment?

A.—Recurrent herpes is almost certainly due to the activation of latent herpes in a carrier. When the eruption is localized to a fixed site recurrence may be due to some focus of infection or irritation within the nerve area of the affected part. Such a focus should be looked for and eradicated if possible. In the case under discussion it might be an anal fissure or a cervical erosion, or it may be due to the irritation of a ring pessary. There is some evidence that full doses of nicotinic acid (50 mg. t.i.d. until facial flushing occurs, and then diminish the dose until symptoms of intolerance disappear) prevent the recurrence of herpes febrilis. With regard to her attack of sprue, it may be significant that this vitamin is essential for

the healthy functioning of the intestinal tract. It would probably be helpful also to prescribe a small dose of some sedative, because nervous factors are also predisposing to recurrent herpes.

Erythromelalgia

Q.—Please describe the signs, symptoms, pathology, and treatment of erythromelalgia.

A.—The modern conception of "erythromelalgia" is of a symptom-complex which may be due to a variety of different causes. The clinical characteristics are redness of the extremities (usually the legs), together with burning pain when the limbs are dependent. The article upon the subject written by Pickering in the *British Encyclopaedia of Medical Practice* (5, 188) may be consulted with profit. Sir Thomas Lewis's writings in *Clinical Science* (London, Shaw and Sons, 1934, ch. 18) and in *Vascular Disorders of the Limbs* (London, H. K. Lewis and Co., 1936) should be studied.

Angina Pectoris and Coronary Thrombosis

Q.—What is the pathological condition in angina pectoris? What is the clinical distinction between angina pectoris and coronary thrombosis? I was taught that Dr. Arnold of Rugby died of angina pectoris. Is it not possible that this attack, which came on when he was in bed, was coronary thrombosis?

A.—Atheroma or arteriosclerosis of the coronary arteries exists in the great majority of patients who have angina pectoris. The blood supply to the myocardium thus becomes restricted. In exercise more work is required of the heart muscle and therefore an augmented blood supply is necessary. Anginal pain develops whenever the available blood supply is insufficient for the needs of the heart muscle. Angina of effort is therefore closely related to exercise, usually walking, and it abates when the exercise ceases.

When thrombosis occurs in a coronary artery there is permanent occlusion of the channel and a prolonged bout of pain occurs, irrespective of the state of rest or exercise. Moreover, since conditions of low blood pressure and slow blood flow conduce to thrombosis, this event is likely to take place in the night or when the patient is at rest in the daytime. Other frequent special features of coronary thrombosis that are not seen in angina of effort or spasmodic angina are: (i) severe shock with lowering of blood pressure for some weeks; (ii) evidences of inflammatory reaction after the attack of pain—e.g., fever and leucocytosis; (iii) local pericarditis due to extension of the cardiac infarct to the surface; and (iv) persisting electrocardiographic abnormalities of special kinds which evolve in certain ways for weeks and months after the attack.

The answer to the last part of the question is in the affirmative.

Trauma and Peptic Ulcer

Q.—Could trauma to a limb—fracture of the lateral malleolus—cause a gastric ulcer in a man who had previously enjoyed good health and who had never had gastric symptoms?

A.—Perhaps the only definite knowledge we have that trauma to a limb may be a causative factor in the production of peptic ulceration is in the case of the so-called "Curling" ulcer of the duodenum, which may be associated with extensive surface burns and was first described by Curling in 1842. This was attributed to embolism, but the modern tendency is to regard it as due to a histamine-like substance, which is liberated from the septic area and is known to produce hyperchlorhydria.

These ulcers are acute and may bleed or perforate, but practically never become chronic. One would suspect that the amount of any such substance set free from a fracture of the lateral malleolus would be very small and unlikely to lead to peptic ulceration. The fact that tens of thousands of such fractures occur without any evidence of ulceration supports this conclusion. In the case described there is no previous evidence of peptic ulcer, and so mere aggravation of a pre-existing lesion is not suggested. Before the question is dismissed, however, the psychological aspect must be considered. That emotional states have a definite influence upon peptic ulceration is now widely accepted, although whether they can be causative is less certain. However, the fracture in this case may be associated with some psychological state, anxiety, etc., which could be an

aetiological factor (perhaps one of many). Otherwise the relationship should be regarded as coincidental.

Sensitivity to Eggs

Q.—My son, aged 4½ years, is extremely sensitive to eggs. Can anything be done about it?

A.—Yes; oral hyposensitization may be carried out by giving increasing amounts of egg diluted in water; particulars of this method can be found in some of the books on allergy and asthma (*Bronchial Asthma*, by Leon Unger, and *Clinical Allergy*, by Louis Tuft). Results are moderately satisfactory but the procedure is long and tedious. It is not used as a routine measure in patients sensitive to eggs but only in special cases, depending on the duration of the sensitivity (after elimination has been tried), the degree of sensitivity, and the circumstances of each individual patient. Hyposensitization by subcutaneous injection is inadvisable.

In the very large majority of patients hyposensitization occurs as the result of leaving all eggs and egg-containing foods—e.g., ovaltine, cake, etc.—completely out of the diet. Hyposensitization takes place gradually, and the time required varies from 6 months to many years, the majority of patients requiring 3 to 5 years. This is the usual method of treatment, and it is almost certain that the child would gradually outgrow his sensitivity on this routine. Cooking reduces the antigenicity of egg to a certain extent, and a small amount of cooked food containing egg might be added to his diet once a year and the effect noted. When no symptoms appear the degree of hyposensitization achieved could then be further investigated. There is no non-specific treatment which is of value.

Dosage of Paraldehyde

Q.—(1) What are the usual extremes of dosage of paraldehyde when this drug is given by the intramuscular route? (2) Are specially large doses given intramuscularly in psychiatric cases, neurological cases, and in cases of eclamptic fits? If so, what maximum dosage may be used intramuscularly? (3) Is paraldehyde ever given intravenously? (4) What is the maximum intramuscular dose of paraldehyde which can be given with safety? (5) Is tolerance to paraldehyde readily acquired? (6) Does paraldehyde deteriorate and lose its potency readily?

A.—The usual dose of paraldehyde when given by the intramuscular route is 4–8 ml. (1–2 fluid dr.). (2) When it has been found that the usual dose is insufficient to produce the desired effect in psychiatric and other cases, then, and only then, the dose can be repeated; after a further interval to observe the effect of the second dose, a third dose may be tried, and so on. There is a very wide variation between the dose which is tolerated by one person and that tolerated by another. There are no figures available for the maximum safe intramuscular dose, but 104 ml. (26 dr.) has been taken as a single dose by mouth without harm. A dose of 120 ml. (30 dr.) has been given rectally to a woman in labour, by mistake, without fatality, but on the other hand a dose of 31 ml. (8 dr.) rectally has caused death. (3) Paraldehyde can be injected intravenously. It must first be dissolved in 9 volumes of saline, and the maximum dose is 4–5 ml. (36–45 ml. of the solution in saline), which must be given slowly. (4) Has already been answered. (5) Tolerance to paraldehyde occurs to some extent with continued use. (6) Paraldehyde is stable and does not lose potency.

INCOME TAX

Car Allowance

A. A. was demobilized and started work as an assistant in general practice in January, 1946. He bought a car for £294, but his principal pays £50 per annum towards the car expenses and provides oil and petrol.

* A. A. can claim the depreciation allowance (20% plus 1/5 = £71) for the period to April 5, 1946. For 1946–7 he can claim the "initial allowance"—i.e., 20% of £294—£71—i.e., £45, and also the depreciation allowance of 25% on the written-down value. He can also claim for the cost of licence, insurance, repairs, and other expenses borne by him. On the other hand he must set against these amounts the £50 cash allowance from the principal, and it may be that some deduction is necessary in respect of private use of the car.

Disposal and Treatment

The disposal and treatment of these cases were as follows: 19 out of 63 (30.1%) required evacuation to hospital, some others were admitted as out-patients, while treatment for all the milder cases was carried out in unit lines, and consisted of reassurance and if necessary rest and sedation. For this purpose barbitone soluble (10 gr. (0.65 g.) nightly or 5 to 10 gr. (0.32 to 0.65 g.) three times a day) was given. In most cases this was sufficient, but if no improvement was noticed after a few days' treatment a psychiatrist's opinion was sought. Some of the more chronic cases of Type 2 were recommended phenobarbitone 1, 2 gr. (32 mg.) t.d.s. for periods of two to four weeks.

Reassurance was considered of prime importance in the immediate treatment; this consisted either, in persuading the man who admitted that he was afraid that his was by no means a unique case—indeed, common to a greater or lesser degree was feeling like him—or in persuading the man who complained of severe headaches or pain over the heart that he was not suffering from a brain tumour or an incurable heart disease. Where possible, arrangements were made with the unit for the patient to be transferred to its detachments outside the Antwerp area.

Observations

A few general remarks might here be made about the effects of the bombardment on the mass of the troops stationed in my area. Many units for months on end were working at high pressure in most vulnerable surroundings, as in petrol or port installations. Few units were fortunate enough to escape having some casualties, and most of us had our full quota of near misses. It was natural enough, therefore, that we all became heartily sick of these things, and many admitted to me, after it was all over, that they felt they could not have stood up to it much longer. The night-time was a much greater strain than the day, and I occupied on duty, and men were generally liable to smoke and drink more than usual.

I have yet to meet the man who was totally unaffected by these bombs—I doubt if he even exists. Many felt tired owing to repeated sleepless nights. To begin with we were able to sleep during the attack—unless one fell too close; but after a time we found ourselves constantly listening for the drone of the engines, following their flight down to earth—and the waiting for the next one.

The lack of this anticipation is one of the things to be said for the rockets, which arrived without preliminary warning, for even a door banging or the sound of a factory siren was liable, after a time, to worry us.

Summary

A series of 63 cases of "exhaustion" seen over a four-months period of the bombardment of Antwerp are reviewed. They are classified into two main types according to their presenting symptoms. No more specialized classification has been attempted.

Treatment consisted of reassurance, rest, and sedatives, in unit lines where possible. Of the cases 30.1% were severe enough to warrant admission to hospital.

The report ends with a few general remarks about the reaction of the mass of the troops to the attack.

REPORT ON MENTAL NURSING

Recommendations designed to give mental nursing a status equal to that of any branch of nursing are contained in a report issued by the Minister of Health and the Minister of Education. The report is that of the Subcommittee on Mental Nursing and the Nursing of the Mentally Defective appointed by the Athlone Interdepartmental Committee on Nursing Services. Mr. Bevan recently described the report in Parliament as a most valuable survey, and said he proposed to obtain without delay the views of the various interested bodies regarding the recommendations, many of which would require legislation.

General Recommendations

The subcommittee considers that the mental nursing service should be held to be comparable in status to any branch of the nursing

Report of Subcommittee on
Mental Nursing H.M. Stationery

profession. "That it is not so is to a large extent due to the public attitude towards mental illness, which involves ignorance of the high qualities of mind and body demanded from the mental nursing service. There are some 29,000 nurses employed in this service—16,400 women and 12,600 men—and we think that, if recruitment is to be stimulated and the quality of the recruits improved, all possible steps must be taken to give the mental nurse a status comparable to that occupied by the nurse engaged in general sick nursing." Among the main recommendations are:

State Registration—Qualified mental nurses should be registered by a statutory body; registration on a supplementary part of the State Register is not satisfactory. All nurses on the Register should be entitled to the designation "State-Registered Nurse." There should be one recognized qualification for the mental nurse in lieu of alternative examinations of the Royal Medical Society, the Association or through the General Nursing Council. The right to practice should rest with the General Nursing Council, subject to certain conditions, which include protection for those holding M.P.A. certificates. If these conditions cannot be agreed, the subcommittee recommends legislation to establish a separate statutory body similar to the Central Midwives Board.

Recruitment and Training—Engagement of female nurses should be the responsibility of the matron, and recruits should have a medical and x-ray examination before entering a hospital. A preliminary training of at least one month is recommended before entrance to hospital. Higher posts in mental hospitals should be held only by nurses with the double qualification of mental and general nursing.

Conditions of Service, etc.—Scale of salary for the mental nurse should be higher than that for the general sick nurse. On hours of work the introduction of a 95-hour fortnight generally is an essential step. Legislation is needed to ensure that our best qualified institutions for the mentally defective should be superintended on the same basis as nurses in mental hospitals. Under the Superannuation Act female staff should be permitted to retire at 50. There should be interchangeability of pension rights from general hospital nursing to mental hospital nursing, and vice versa. Student nurses, particularly girls, should normally live in the hospital. Permission to leave out if the hospital authorities are satisfied that the interests of the nurse. All trained mental nurses should be permitted to permit a live out ward man should be employed, and where possible the ratio of nurses on day duty to patients (nurses to patients) should be substantially reduced.

Status of Mental Nursing

The subcommittee has no doubt that there still exists an inferior view of the nursing of the mentally ill, which is, sometimes, considered an occupation inferior to the nursing of the bodily sick. This impression contributes as much as any other factor to the difficulty when mental hospitals experience in obtaining enough female staff. It is a matter of national importance that the modern outlook on mental illness should be understood and that the value and interest of mental nursing should be recognized. While no other form of nursing makes greater demands upon the nurse, there is another side: asylums for detention and protection of the inmates have given place to mental hospitals, fully equipped with a view to the recovery of the patients.

Great advances have been made in recent years, and modern methods of physical treatment require specialized training. The medical staff now need highly skilled mental nurses to assist in carrying out the detailed technique of such methods of treatment as insulin therapy, convulsive therapy, insulin treatment, and prolonged narcosis. In all these the preparation of the patient and the equipment, the care of the patient during treatment, and the subsequent nursing demand much skill and knowledge.

On thorough investigation most cases of mental illness are found to be the result of a combination of physical and psychological factors. It follows, therefore, that the mental nurse has also to receive an adequate training in the nursing treatment of bodily ailments and diseases, both surgical and mental. There is every justification for the recognition of mental nursing as a highly skilled branch of the profession and entitled to a worthy status. The traditional stigma attached to mental illness has not yet been eradicated from the public mind, but there are signs that a more enlightened view is developing, and much could be done by judicious publicity on behalf of the mental nursing service to dispel the public feeling that contact with the mentally ill is something to be avoided.

Discipline, Food, and Recreation

The discipline of the hospital should not extend to the nurse when off duty. She should then, so far as is possible, have the personal liberty of a private individual. A small standing committee or nurses' council should be set up in each institution to scrutinize the rules, consider grievances, and suggest reforms. The cafeteria system of feeding should be introduced where possible. There should be provision for obtaining light meals and for the entertainment of

by mattress sutures of unsorbable material. As for poor incisions, he mentioned with disapproval "trans-rectus" incisions, and in particular Battle's incision.

Adequate Access and Firm Scarring

Mr. DIGBY CHAMBERLAIN said that three things had to be borne in mind when making an abdominal incision: adequate access to the structure to be operated on, the leaving of a firm scar after healing; and (a minor consideration) a cosmetic result. Concerning incisional hernia and burst abdomen, he referred to a paper by E. S. J. King, of Melbourne, in the *British Journal of Surgery* (1935, 23, 35), in which he expressed the opinion that such hernias started by the cutting out of the peritoneal stitches or the escape of a tag of omentum between them. As for the size of the incision, it had been said that if one was in a strange country and required an abdominal operation one should ask which surgeon made the biggest incision and go to him. Inadequate incisions might mean that diseases in the abdomen which were unsuspected were missed. Every abdominal exploration should allow the surgeon to pass in review quickly the important organs inside the abdomen. The firmness of the scar depended largely on the suturing of the peritoneum. Adequate suturing of that layer would prevent the incidence of post-operative hernia or burst abdomen, and such suturing was as much dependent on the anaesthetist as on the surgeon. In making an abdominal incision nerves should be avoided, and muscles were better displaced than divided. As a standard incision he used the paramedian in operations for the stomach and duodenum. Paramedian incisions were perfectly adequate for colon work. For operations on the biliary tract he used a right paramedian incision almost exclusively. In closing the abdomen he used a continuous catgut stitch for the peritoneum and if it was thin he took a small piece of the under-surface of the rectus muscle with each stitch in order to reinforce it. He added that abdominal incisions on the whole were not a matter of great interest to surgeons, who only too often left it to their assistants to close the abdomen, but, however much he listened to the assistant, he considered that the surgeon should close at least the peritoneum in view of the importance of that step in relation to incisional hernia.

Prof. JOHN BEATTIE made some general observations on the metabolic disturbances which followed the infliction of a surgical wound and on the physiology of healing. He stressed in particular the need for a high protein intake, and also pointed out the function of cortin in promoting repair in cases of injury, and the high vitamin C requirements in view of the increased production of cortin.

The PRESIDENT referred to the firmly rooted idea among students that an incision began to heal at one end and the process of healing continued gradually towards the other end, so that they had a prejudice against a long incision, which they thought took a longer time to heal. He also asked for an opinion about stab-drawing of the abdomen.

Mr. RODNEY MADGOT said that he had been brought up on vertical incisions, he was taught median and paramedian incisions, and gradually, lately, he had been going more oblique. The transverse incision had the disadvantages that it took a long time to make, was very bloody, and left a weak abdominal wall, so that hernia was prone to arise afterwards.

For and Against Battle's

Sir CLAUDE FRANKAU said that thirty years ago he was a convinced "muscle-splitter," but very soon he abandoned the practice. Contrary to General Ogilvie, in certain conditions he supported Battle's incision. It was the only adequate and proper incision for an appendix about which one was sure. It gave perfectly good access, no nerve was injured and no vital spot was obtained if care was taken to drain at the upper end. Lord Moyrhan once spoke of the mercifulness of the long incision. Arising out of that was the great desirability that the incision should be such that heavy retraction was not wanted afterwards. The worst thing for the patient in any abdominal operation was for the surgeon to be required to use any form of heavy retraction; it should be as light as possible.

Mr. W. E. TANNER said that when he was a house-surgeon he watched Arbuthnot Lane perform his operations. When

operating for a bad peritonitis he did not close the peritoneum at all. He put a tube right along the wound and closed up the other layers. His idea was that paralytic ileus or dilatation of the stomach in these cases was caused by distension in the abdomen. He was bound to say that he saw some of these cases heal perfectly.

Mr. HAROLD DODD said that a very good incision for the appendix, which would deal also with the ruptured ectopic, and which was coming into greater use, was the Ruthersford Morrison iliac incision, often described by Prof. Grey Turner. The gridiron incision was attractive but difficult. He had given up midline incisions on account of the likelihood of hernia. He emphasized the importance of careful protection of the wound edges if first-class healing and freedom from burst abdomen or incisional hernia were desired.

In some further discussion Battle's incision was condemned and defended. One speaker said that as a house-surgeon he had two surgeons above him, one of whom practised Battle's and the other the gridiron, and as a consequence of the results he saw he would never use the former. The gridiron found more advocates than critics. Mr. SOLLY COHEN said he had never seen an obstruction after a gridiron incision, and he believed that Surg. Rear-Adm. Gordon-Taylor once stated that he had never had to open an abdomen for obstruction following that incision. A registrar, Mr. MUNRO, urged the value of a short incision in certain cases, and expressed himself rather surprised at the tendency to long incisions by his seniors.

General OGILVIE, in reply, said that it was undoubtedly the right thing not to use the main incision for drainage, but to make a separate tab. He protested against some of the eccentric incisions—"alphabetical incisions" they had been called in the course of the discussion because a number of letters of the alphabet appeared to be imitated—which were published in certain literature, particularly American. They belonged, he said, rather to the tradition of Heath Robinson than to that of John Hunter. With good anaesthesia especially with field block of the abdominal wall, he thought that everything desired could be got out of the median incision, and he had had no misfortunes with it. It was true that one was dealing with only one layer, but with a tremendously strong layer which could be sutured with the utmost security. He thought that the controversy over Battle's incision should be left where it was.

Mr. CHAMBERLAIN, also in reply, said that one speaker had mentioned Lane's practice of suturing the abdomen and leaving the peritoneum unsutured. He could not subscribe to that procedure and he hoped that no one in that company was now in favour of it.

Correspondence

R.M.B.F. Christmas Gifts

SIR.—It is with great pleasure that I can now announce that the Christmas Gifts appeal which I launched through your columns has reached the magnificent total of £2,127—a new record. In view of the high prices and the scarcity of the amenities of life I asked my colleagues for £2,000, a sum which, in view of last year's record, I scarcely dared to hope would be achieved, but which has actually been passed by a handsome margin. This means that all our beneficiaries are receiving £4 as a Christmas gift, and there is enough over to give some of the poorest £2 for the New Year.

My committee and I are deeply conscious of the great help afforded by the medical press in supporting and giving publicity to this appeal, and to you and your colleagues of the press as well as to all the generous contributors in the profession we tender our most cordial and grateful thanks.—I am, etc.,

ARNOLD LAWSON,

President, Royal Medical Benevolent Fund

Printer, S.W.15.

A Fundamental Principle

SIR.—On reading Prof. J. A. Ryle's letter (Dec. 29, 1945, p. 936) I was amazed and distressed to find one of the leaders of our profession advocating "some measure of direction" of

Patients were treated, as they were admitted to hospital, with one or other of these three courses in rotation, so as to obtain random sampling of subjects. Each patient was followed up for six months after treatment. This experiment is not yet completed, but it has become clear that paludrine in the dosages described above has no greater effect on the relapse rate than mepacrine, and is therefore in this respect apparently less efficient than a combination course of quinine (10 gr. (0.65 g.) t.d.s.) and pamaquin (10 mg. t.d.s.) given concurrently for 10 days, as originally recommended by Sinton (Army Malaria Research Unit, 1944).

Treatment of *P. falciparum* Infections

The therapeutic activity of paludrine in *P. falciparum* malaria was also examined by Maegraith, Adams, *et al.* (1945). The patients were either Service men or Merchant Navy personnel recently returned to England from either West or East Africa. Of the 22 patients treated in the first series of cases, 16 were suffering from primary attacks of malignant tertian malaria. They had received no antimalarial drug for at least a fortnight before treatment with paludrine was started. As in the cases of *P. vivax* malaria, when possible the patient was watched in hospital for a few days before paludrine was administered, but this period of observation had often to be omitted because of the severity of the illness.

Paludrine was administered orally under the same conditions as in the treatment of benign tertian malaria, in doses ranging from 50 mg. to 600 mg. twice daily for 14 days. Doses of less than 50 mg. twice daily have not yet been given in malignant tertian malaria. These doses were found to control the clinical attack effectively.

The clinical recovery was usually as rapid as in benign tertian malaria, and the action of the drug on the asexual parasites was as efficient as in the case of *P. vivax*. Paludrine appeared to have no action on the sexual forms of *P. falciparum*, which, when present, remained in the peripheral blood throughout treatment.

Recently cases of malignant tertian malaria have been treated as they were admitted to hospital, with either 100 mg. or 200 mg. paludrine twice daily for 14 days. Attempts have been made to follow up patients subsequent to discharge from hospital, but this has proved difficult in some cases, especially with coloured seamen. It is not known for certain, therefore, what effect paludrine has on the relapse rate of malignant tertian malaria, but the evidence at present available indicates that after dosage of 100 mg. twice daily or more for 14 days subsequent relapses do not occur. This finding is in agreement with Fairley's observations in sporozoite-induced malignant tertian malaria, in which he found that paludrine acted as a causal prophylactic.

Treatment of *P. vivax* Malaria with a Single Dose of Paludrine

Fairley (1946) has recently reported that he and his colleagues in Australia have obtained clinical cures in cases of trophozoite- and sporozoite-induced *P. vivax* malaria after the administration of single doses of 100 mg. paludrine.

We have obtained similar clinical cures in naturally acquired *P. vivax* infections with single doses of the drug. The patients treated in this series of experiments have all been Service men suffering from relapsing or delayed primary benign tertian malaria. After the usual interval of observation required to determine whether the malarial attack is likely to be imme-

diately self-limited, paludrine is administered orally followed by a good draught of water.

Single doses of 50, 100, 200, 300, and 400 mg. have been employed. The effect of any of these doses on the clinical course of the malarial attack is rapid and almost as fast as it is with multiple twice-daily dosage. The patient feels better within a few hours of taking the drug, and, although there is usually a rise of temperature above normal on the "paroxysm day" immediately subsequent to treatment, this fever is not usually associated with a rigor. There is no further rise of temperature until relapse occurs in due course. The asexual parasites disappear more slowly from the peripheral blood than they do after repeated dosage, but the blood is usually clear of parasites by the fourth or fifth day. Sexual forms disappear more slowly than the asexual parasites.

Parasites reappear in the peripheral blood three to eight weeks after administration of the single dose of paludrine; their reappearance is usually accompanied by the clinical signs of malaria. Such relapses respond immediately to a further single dose of the drug, a dose of 100 mg. being sufficient to abort the attack. We have found that relapses of this sort can be treated efficiently with 100 mg. paludrine independently of the size of the previous dose. If a single dose of 100 mg. paludrine

is administered weekly after the treatment of an acute attack the relapse is held off indefinitely. We are now treating on these lines all patients with relapsing or delayed primary benign tertian malaria. On admission the patient receives a single dose of 300 mg. paludrine accompanied by a glass of water. A week later he is given one 100-mg. paludrine tablet, and is told or discharged to take similar tablet once weekly for the next six months. Patients are followed up by means of printed post-

cards. After six months they cease taking the drug, but are followed up for a further six months. Results of this experiment are not yet available, but it is hoped that the process of exposing the parasites to a long series of intermittent dosages of paludrine may prove more effective in producing radical cure of *P. vivax* infections than have the continuous fortnightly twice-daily dosage regimes previously used in treatment.

The control of the acute clinical attack of *P. vivax* infection by paludrine must depend upon the effective concentration of the drug in the fluid surrounding the parasite—i.e., within either the red cell or the blood plasma. The lowest single dose so far known to have an effect on the acute attack is 50 mg. The maximum plasma concentrations of the drug reached after this dosage may be taken to represent the minimum level known to be effective against the parasite. After single dosage with 200 mg. or more we have found that this effective level is maintained for more than 48 hours in spite of the rapid excretion of the drug in the urine. Single-dose therapy may therefore be regarded as a method of providing effective drug concentrations lasting not just for a few hours but for several days. The same argument should apply to mepacrine, which is excreted much more slowly and incompletely than paludrine (Army Malaria Research Unit, 1945). Three patients suffering from relapsing benign tertian malaria were therefore given a single dose of 400 mg. mepacrine orally, followed by a draught of water. Clinical cure occurred in all three with the same speed as in dosage with paludrine. Some abdominal discomfort was noted in all. One case relapsed 10 days after the administration of the mepacrine; the others were given 100 mg. paludrine weekly, as above.

Chart showing the effect of a single dose of 300 mg. paludrine in a case of B.T. relapse. Quotidian fever; five paroxysms allowed.

The activity of smaller doses of paludrine and mepacrine is now being investigated. There seems to be little to choose between single doses of paludrine and mepacrine in the treatment of the acute attack of relapsing or delayed primary benign tertian malaria, apart from the slight abdominal discomfort sometimes produced by the latter. The advantage of paludrine, however, lies in its being a colourless drug, and therefore much more satisfactory to prescribe over a long period.

It must be remembered, too, that the activity of paludrine against the exo-erythrocytic form of *P. gallinaceum* is not shared by mepacrine. The recent experiments of Fairley and his co-workers in Australia suggest that under suitable conditions paludrine may act on the as yet unidentified exo-erythrocytic forms of the human *P. vivax* parasites. It is possible that dosage with paludrine may therefore materially affect the relapse rate of chronic B.T. malaria, upon which mepacrine has little effect, if the drug is given, as described, in weekly single doses over a prolonged period.

Our results in the treatment of benign tertian malaria will possibly be exposed to the hoary criticism that the cases we have dealt with would have cured themselves without the administration of the drug. Such spontaneous recovery does occasionally occur, but this argument (which, of course, applies to all antimalarial research) practically amounts to declaring that all cases of benign tertian malaria admitted to our wards spontaneously subside after the second or third rigor. We have tried to counter it by observing all our cases before treatment until they have had at least two rigors (with unchanged or rising parasitaemia). In some cases we have allowed the patient to have five or more rigors, after which clinical cure has been obtained immediately following the administration of a single dose of paludrine. (The temperature chart of such a case is here reproduced.)

Summary

Paludrine is a colourless slightly bitter drug belonging to a class of chemical compound not previously known to have antimalarial activity. Unlike most other antimalarial drugs, it has been found to have an action on the exo-erythrocytic forms of the parasites in *P. gallinaceum* avian malaria.

It has been used successfully in the treatment of benign tertian malaria (both in relapses and in delayed primary attacks) and in acute attacks of malignant tertian malaria (both primary cases and relapses).

It has a very wide therapeutic range of activity. Doses of 10 to 750 mg. and of 50 to 600 mg. twice daily for 14 days have been used successfully in the treatment of benign and malignant tertian malaria respectively. No serious toxic side-effects have been observed with such dosages, although occasional nausea and vomiting may occur at dosages of 500 mg. or more twice daily.

The administration of single doses of 50, 100, 200, 300, and 400 mg. will produce clinical cure of relapsing and delayed primary cases of benign tertian malaria. Similar effects have been obtained with single doses of 400 mg. mepacrine.

Twice-daily dosage regimes for 14 days have no greater effect on the relapse rate of benign tertian malaria than full courses of mepacrine. The administration of one dose of 100 mg. weekly after treatment of the acute attack with a single dose of 50 to 400 mg. has so far been found to keep the patient free from relapses. The effect of this therapy over a period of six months is being investigated.

King Edward's Hospital Fund for London has issued a revised edition of its out-patient time-table for London hospitals. All doctors in the Metropolitan Police District are receiving copies, and a considerable number are being sent to infant welfare and other health societies. This time-table helps patients and their doctors to prevent the waste of time which sometimes results from attending hospitals at the wrong hour, or even on the wrong day. A limited number of copies are obtainable free of charge from George Barber and Sons, Ltd., 23, Fumival Street, E.C.4.

EXTRARENAL URAEMIA

BY

S. G. ZONDEK, M.D.

(From the Department of Internal Medicine of the Hadassah Municipal Hospital, Tel-Aviv)

The appearance of renal failure in the course of organic renal disease does not seem to be either extraordinary or strange. This does not apply to those rather frequent cases of renal failure which are met with in diseases not primarily involving the kidneys, and in patients who apparently had previously never suffered from any kidney trouble. The most varied pathological conditions may give rise to this kind of renal failure. The following may be mentioned first: any disease accompanied by considerable loss of water and/or salts (vomiting and/or diarrhoea); major operations of any kind; burns; crushing and other grave injuries. Renal failure may also be observed in severe liver affections, particularly when complicated by jaundice (hepato-renal syndrome); in myocardial infarction; and in general infections of various kinds.

All these cases of renal failure are of an acute character, and are cured within a few days, or end fatally, with oliguria, anuria, and, finally, uraemic coma as their most prominent symptoms. The question arises whether these cases of extrarenal or, according to Fishberg (1939), prerenal uraemia have a common basis, and, if so, what is its nature? As suggested in a previous publication, renal failure in the above-mentioned conditions should be defined as functional, because these cases, as has been found by many other authors, display either no pathological changes at all in the kidneys or only changes insufficient to account for the grave functional disturbances. If there are changes, these are more or less of the same character irrespective of whether the fatal uraemia was caused by burns, by crushing injuries or other forms of trauma, or even by pyloric stenosis (Beall, Bywaters, Belsey, *et al.*, 1941; Young and McMichael, 1941; Young, 1942; McLeitchie, 1943; Darmady *et al.*, 1944). The tubules are affected, while the glomeruli are generally found to be normal, although the nature of the functional disturbance—oliguria or anuria—points particularly to functional changes in the glomerular apparatus (Fishberg, 1939).

"Extrarenal uraemia," or "functional renal failure," as it may also be called, is closely connected with "extrarenal azotaemia" (Zondek, 1944). The latter term designates only those cases with high non-protein nitrogen in the blood due not to renal failure but to increased endogenous breakdown of protein. The non-protein nitrogen is moderately increased in the blood and markedly increased in the urine (up to 50 g. and more urea per day, thus considerably exceeding the quantity to be expected from the protein intake). The good renal function in these cases is shown also in the ability to secrete urine with optimal urea concentration (up to 5%), and in the satisfactory result of the urea clearance test. The high urea excretion is in marked contrast to a very low excretion of sodium chloride (dissociation of the urea-sodium-chloride excretion). The ratio of sodium chloride to urea in the urine may be 1:20 and even 1:50 and higher. The low excretion of sodium chloride (sometimes less than 1 g. daily) is not limited to the cases with chloride loss due to vomiting, diarrhoea, etc.; it is not caused by hypochloraemia, but is one of the reactions which take place in connexion with the increased breakdown of protein.

There is a definite relationship between extrarenal uraemia and extrarenal azotaemia (Zondek, 1944): (1) extrarenal azotaemia appears under the same morbid conditions as extrarenal uraemia—that is, the same disease which in one person may lead to extrarenal uraemia may cause in another extrarenal azotaemia; (2) in every case of extrarenal uraemia, extrarenal azotaemia is also present. In other words, one patient may react with extrarenal azotaemia alone, whereas the other reacts with extrarenal azotaemia plus renal failure.

Extrarenal Azotaemia

If the increased endogenous breakdown of protein is not on too big a scale there is no rise in non-protein nitrogen in the

blood, but the typical changes in the composition of the urine are present. These cases may be defined as the abortive form of extrarenal azotaemia, and although they are of no particular clinical importance they merit our attention for a better understanding of the main problem. The following two cases are examples of this group:

Case 1.—A man of 30 fell ill with dysentery and a high temperature two days before admission to hospital. On the first day in hospital the blood urea was 46 mg., three days later 36 mg.; NaCl concentration in the urine during this period: 2.1, 2.6, and 2.0 g. per litre, with urea concentration 35, 40, and 42 mg. per 100 ml. Total daily excretion of NaCl ranging from 1.0 to 1.2 g., total urea excretion from 28 to 31 g. Urine free from albumin and other pathological elements.

Case 2.—A man of 38 fell ill one day before admission to hospital with myocardial infarction of the posterior wall. Very slight vomiting and sweating during the first two days. On the second day of his illness there was a moderate rise of temperature, which continued for four days. On admission his blood pressure was 100/70 mm. Hg, falling during the following four days to 90/50 mm. Hg. Blood on the day of admission: NaCl 580, urea 50, and uric acid 3 mg. per 100 ml.; four days later, urea 36 and uric acid 4.2 mg. per 100 ml. Urine during this period: NaCl concentration 2.2–2.6 g. per litre, urea 48–50 g. per litre; total daily excretion: NaCl 1.4–1.8 g., urea 26–30 g. Urine free from albumin, etc.

The occurrence of renal failure is, as already mentioned, a not uncommon event after serious injuries or burns. So far I have had no opportunity of examining such patients; but it is unquestionable that in cases of burns and injuries pure extrarenal azotaemia may be met with. According to Cuthbertson (1936), Lucido (1940), Croft and Peters (1945), in burns at least there is a greatly increased urinary excretion of urea due to abnormal protein breakdown. No attention, however, was paid in these examinations to the sodium chloride excretion; but the latter can be assumed to be very low in these cases. In this connexion the recently published paper of Cooke *et al.* (1945) refers to injuries with "systemic reaction" and presents the findings in the blood and urine of the patients in question. The greatly increased urinary excretion of nitrogen-containing substances is stressed by these authors. The figures for urinary output are sometimes as low as 0.25 g. of chloride daily, while those for total nitrogen reach 20 g. and more. The results of the urine examinations made on various patients were as follows:

Total nitrogen (g.)	18.6	18.1	27.9	18.4	25.2	30.5	19.4	27.2
Total chloride (g.)	0.25	0.27	1.07	1.82	2.4	4.1	0.62	4.7

Another point of interest is that among these cases with marked dissociation in the excretion of sodium chloride and nitrogen-containing substances there were a number whose blood urea did not increase at all. These findings correspond closely with those described above in such affections as dysentery and myocardial infarction and also represent an abortive form of extrarenal azotaemia.

Extrarenal Uraemia

An essential feature of renal failure which has been observed in cases of uraemia on the basis of primary renal disease is decreased excretion of sodium chloride and urea in the urine. The relationship, however, may be the same as in healthy people. A ratio ranging between 1:1 and 1:4 covers even the variations made possible by the nutritional factor. In cases of extrarenal uraemia the ratio of sodium chloride to urea mostly ranges between 1:10 and 1:20 (Zondek, 1944). There is no need to explain why the urea excretion is not as high in these cases as in pure extrarenal azotaemia, with a ratio varying from 1:20 to 1:50 and even higher. On the other hand, the difference in the sodium chloride and urea excretion found in these cases of extrarenal uraemia is large enough to prove the simultaneous existence of an azotaemic process caused by increased endogenous breakdown of protein. There are, however, extremely severe cases of renal failure which, according to their aetiology, must be considered as belonging to the group of extrarenal uraemia, too, and they behave, so far as the sodium chloride and urea excretion is concerned, like cases of true uraemia due to primary renal disease. But even in these cases the combined pathology of renal failure and extrarenal azotaemia may be assumed, the latter concealed by

the severity of the former; the characteristic symptoms of the extrarenal azotaemia may not be revealed until after the lessening or disappearance of the renal insufficiency, as seen in the following case.

Case 3.—A man of 56 developed a very grave form of infectious hepatitis three days before admission to hospital. Besides the usual general symptoms he had severe pains in all his limbs. From the second day of his illness there was constantly increasing jaundice. In its clinical course the disease was very similar to Weil's disease; all bacteriological and serological examinations were, however, negative. In the last 24 hours before admission oliguria was noted, and this became more marked during the following 48 hours; daily urine output not more than 200 ml. On the day of his admission: blood, bilirubin (van den Bergh) 8.8 mg. per 100 ml., Takata-blood, bilirubin (van den Bergh) 8.8 mg. per 100 ml., NaCl 560, urea 223, uric acid 10.5 mg. per 100 ml.; urine, traces of albumin, bilirubin +++, cephalin and formol test ++, NaCl 2 g. per litre, urea 3.4 g. per litre. The patient was treated with infusions of saline and 5% glucose, and on the fourth day after the beginning of the oliguria diuresis set in; the daily urine output on the following nine days was 1,100–3,000 ml. In spite of the improving diuresis there was a further increase of urea in the blood, reaching its climax of 450 mg. per 100 ml. on the third day of the improved diuresis. From that day onwards continuous fall of the urea. On the ninth day of the improved diuresis, several hours before the patient's death, urea 108 and uric acid 3 mg. per 100 ml. During the whole period the NaCl excretion, in spite of its abundant administration (daily saline infusions of 1,000 ml. for ten days), was very small; its concentration in the urine mostly between 1.3 and 1.9 g. per litre, the daily total between 2 and 5 g. The urea excretion, on the other hand, with the improvement in the diuresis steadily increased: its concentration in the urine between 15 and 32 g. per litre, its daily quantity between 27 and 98 g. The urinary ratio of NaCl to urea of about 1:2 during the days of the oliguria rose to 1:15 and 1:20 after the improvement of the diuresis. On the fourteenth day of his illness the patient succumbed. For the exact data of the case see the Table.

Details of Case 3

	April:	8	9	10	11	12	13	14	15	16	17	18
Blood (mg. per 100 ml.):												
Bilirubin		8.8	9.5				13.8			16.3		
NaCl		580						600				
Uric acid		10.5	17.2	14.0	11.0	13.5		6.2	4.6			3.4
Urea		223	283	300	450	380		211	133			108
Urine (g. per litre)												
NaCl		2.0	1.8	2.6	1.6	1.3	1.4	1.4	1.8	1.8	1.9	5.5
Urea		3.4	3.5	11.2	15.2	17.6	17.6	28.0	32.8	30.4	28.0	19.7
Urinary excretion daily (g.)												
NaCl		0.4	0.35	2.9	2.9	3.6	3.3	4.8	4.5	5.0	6.7	17.4
Urea		0.68	0.7	12.4	27.3	49.2	40.5	91.2	82.0	85.1	98.0	59.2

Post-mortem Examination (Dr. Karplus).—Liver: weight 1,960 g.; macroscopic appearance normal; microscopically, periportal infiltration. Kidneys: except for hyperaemia glomerular apparatus entirely normal; Henle's loops without definite findings, but marked change ranging from degeneration to necrosis in the first and second convoluted tubules.

The fact that after cessation of the oliguria the amount of sodium chloride excreted in the urine remained at its previous low level, while the quantity of urea continuously increased, must be considered proof of the existence of an extrarenal azotaemic process. It might be claimed that the enormous urea excretion was due only to the retention of urea in the body during the anuric stage, but this argument is not justified. The oliguric phase has existed for three days only, during which period the amount of urea retained could not possibly have been large enough to account for a daily urea excretion of from 27 to 98 g. for nine successive days (the exact quantity of the excreted urea during this period amounted to 544 g.). The entire process is not comprehensible except by assuming that there was from the very beginning an enormously increased endogenous breakdown of protein, the detection of which (dissociation of the urinary excretion of sodium chloride and urea) was impossible until the phase of grave renal failure had passed. The patient died in spite of overcoming the renal insufficiency. On the other hand, among the various factors causing the death of the patient, that of protein breakdown should not be neglected. In any case an excretion of more than 500 g. of urea within nine days points to an enormous loss of body protein and this, it may be stressed, not at the expense of the liver tissue.

the weight of which did not decrease (see the necropsy report). Not always in the group illustrated by Case 3 can the extrarenal azotaemic process be detected after the improvement in the renal failure; as a rule the protein breakdown does not continue for longer than the renal failure, or not for a period sufficiently long to make the proof as clear as in Case 3.

If extrarenal uraemia in the group of diseases quoted in this paper is always associated with extrarenal azotaemia, we may consider the latter (increased endogenous breakdown of protein) to be the cause of the appearance of renal failure. As already suggested by Volhard (1931) in the case of post-operative uraemia, and by Beall *et al.* (1941) and Eggleton (1944) in the case of crushing injuries, the pathological breakdown of protein may lead to the formation of katabolic toxic substances which affect the kidneys and lead to renal insufficiency (nephrotoxic theory of Bywaters). The equally good response of both extrarenal azotaemia and extrarenal uraemia to the same treatment—administration of sodium chloride (Zondek, 1944)—also suggests the interdependence of both processes. However, there may be arguments against this suggestion. Though extrarenal azotaemia is undoubtedly the sequel of protein breakdown, renal failure could be caused by quite another process connected with the primary disease. One factor which should be considered is the fall in blood pressure, another the decreased renal blood flow (Fishberg, 1939), both met with often in the various conditions in question. In animals at least a fall in blood pressure and decreased renal blood flow affect renal function unfavourably, but these two factors can hardly be regarded as responsible for the renal failure in our cases. Thus, in myocardial infarction, a disease characterized by a fall in blood pressure, and probably also by decreased renal blood flow, pure extrarenal azotaemia with very good renal function may be observed (see Case 2). The interdependence between extrarenal azotaemia and functional renal failure should not be overstressed, but their close correlation cannot be doubted.

Discussion

Like symptoms or symptom-complexes appearing in the most different groups of diseases are rightly interpreted as of a non-specific nature. Extrarenal azotaemia should be regarded as such a symptom. It is not the specific nature of a special primary disease which is responsible for this reaction, but rather a factor so far unknown to us and apparently connected with the gravity of a number of different diseases, such as acute enteritis, hepatitis, myocardial infarction, injuries, burns, acute infections, etc. Actually there is no disease which cannot cause extrarenal azotaemia. There is a close relationship between extrarenal azotaemia and functional renal failure, the former being potentially the latter. Given the same basic disease, a person may react, if at all, either with extrarenal azotaemia alone or with extrarenal azotaemia plus functional renal failure—that is, extrarenal uraemia. The range of intensity of the possible reaction is very wide; one end is marked by the mildest form of extrarenal azotaemia, evidenced only by the appearance of the typical changes in the composition of the urine; the other by the most severe form of renal failure with oliguria or even anuria. If with accurate diagnostic methods very slight disturbances in the function of the kidneys should be detected also in cases of so-called pure extrarenal azotaemia, our views would not need to be revised. In these latter cases the extrarenal azotaemic process caused by increased endogenous breakdown of protein would remain the chief factor responsible for the clinical findings. Functional renal failure may also be produced in the absence of an extrarenal azotaemic process; thus katabolic substances other than those from protein katabolism, and exogenous substances (e.g., sulphonamides), may affect the kidneys. But even allowing for this possibility, the vast majority of all cases of functional renal failure may be associated with extrarenal azotaemia. Since extrarenal azotaemia is in these cases non-specific, the accompanying process of functional renal failure must be considered in the same light, though it may be regarded as the specific reaction of the kidneys to a non-specific process—that is, extrarenal azotaemia and what it represents.

The question arises why one patient reacts with extrarenal azotaemia alone and another with extrarenal azotaemia plus

functional renal failure. As in many other circumstances a constitutional factor unknown to us may play the decisive part, but other factors must be taken into account. If renal failure is a sequel to the extrarenal azotaemic process, importance must be attached to the intensity of that process. In this connexion it may be recalled that in Case 3, with particularly grave renal insufficiency, the body protein broken down within nine days amounted to nearly 2 kg.; the urea excretion alone, excluding all other nitrogenous substances, was about 550 g., while the protein intake during this period was negligible. The condition of the kidneys before the onset of the disease is another important factor; kidneys affected by arteriosclerosis or damaged by any other chronic disease must be assumed to be more likely to react with renal insufficiency than those of young and healthy people.

If the most different groups of diseases may cause extrarenal azotaemia and functional renal failure, might not the same pattern apply also to primary renal disease? Take the following not uncommon case: A patient has been suffering from an uninfected renal calculus for a long time without any disturbance in the renal function. A sudden infection of the urinary tract may lead to acute uraemia. Might the uraemia not be of the same type as in acute liver affections and in diseases of other specific organs? There is no definite answer to this question as yet, but the following fact is remarkable. The administration of sodium chloride (infusions of saline or saline plus glucose) is an efficient form of treatment in extrarenal azotaemia and extrarenal uraemia, as also in Fishberg's "prerenal" uraemia. There is, too, no better treatment for uraemia in a case of renal calculus, excepting only specific treatment (operation) of the stone itself. The withdrawal of sodium chloride in all renal diseases to the extent to which it was common previously is surely not the right treatment and may even be harmful. We are, however, still very far from being in a position to decide definitely on the indications for its administration in the various renal affections. Our view that uraemia in organic renal disease may sometimes be of the type of extrarenal uraemia—that is, functional renal failure—can serve as a clue to an understanding of the therapeutic efficiency of sodium chloride in at least a special group of cases of renal disease. It is undoubtedly difficult to decide in a specific case of organic renal disease with uraemia whether the renal failure is non-specific—extrarenal and functional in nature—or a specific sequel to the existing organic renal disease. Possibly our examinations may prove helpful in overcoming these difficulties to a certain extent at least. The detection of an extrarenal azotaemic process (marked dissociation of sodium chloride and urea excretion) would permit us to regard the existing renal failure as of extrarenal and functional character, and might prompt us to try sodium chloride therapy, provided there is no definite contraindication. A case belonging to this group and successfully treated with sodium chloride has been reported (Zondek, 1944).

Knowledge of increased breakdown of body protein as the cause of extrarenal azotaemia has been stressed by Croft and Peters (1945) and has prompted in cases of burns a diet rich in protein. I leave open the question whether this line of treatment can be successfully applied in any case of extrarenal azotaemia. Let us bear in mind, however, that extrarenal azotaemia contains in itself the potentiality of renal failure, and it remains to be seen whether or not the development of the latter might be affected by any excessive administration of protein.

Summary

Extrarenal azotaemia is caused by increased endogenous breakdown of protein and brings about an increase of urea and other nitrogen-containing substances in the blood, with a simultaneous excretion of great quantities of urea and small quantities of sodium chloride in the urine (dissociation of the sodium chloride and the urea excretion).

There is also an abortive form of extrarenal azotaemia, the changes in the composition of the urine being the only abnormality found.

There is a connexion between extrarenal azotaemia and extrarenal uraemia.

Extrarenal azotaemia and extrarenal uraemia are non-specific symptom-complexes which may be produced by a variety of diseases or injuries.

PULMONARY EXCHANGE DURING ARTIFICIAL RESPIRATION

BY

R. R. MACINTOSH

AND

WILLIAM W. MUSHIN

(From the Nuffield Department of Anaesthetics, Oxford)

The relative merits of the various methods of artificial respiration have long been a subject of dispute, and each of them still has its advocates. This lack of agreement is doubtless due mainly to the fact that in ordinary circumstances it is impossible to compare the efficiency of the various procedures. In any real emergency skilled personnel and scientific recording apparatus are rarely available. In any event, the prime object must be the resuscitation of the victim; if the method used is successful it is deemed to be a good one, but if the patient dies it is assumed that he was beyond saving.

It is true that the volume of air passing in and out of the lungs in artificial respiration has been recorded, but the value of the conclusions reached is doubtful. For the considerable anatomical differences between man and other mammals make the conclusions reached on the latter largely inapplicable to man. Experiments on man are valueless unless the volunteer is unconscious, toneless, and not breathing. Yandell Henderson (1938) confirms that the tonus of the respiratory muscles of the conscious subject varies so that the respiratory minute volume is kept almost constant, whatever the method used whatever the rate of the chest movements. A warm cadaver might furnish figures of value, but the means is open to obvious objection, and any experiments carried out after rigor mortis had set in would be useless.

One of our colleagues (E. A. P.) felt that the various methods of artificial respiration could and should be evaluated on a subject depressed to simulate a victim *in extremis*. He asked to be anaesthetized profoundly and brought to respiratory arrest. Artificial respiration now became essential, since almost the only evidence of life was that the heart-beat continued. The various methods of artificial respiration were tried in turn, and the pulmonary exchange recorded on a kymograph.

The subject was a healthy young man of about 10 st. (63.5 kg.). The larynx was anaesthetized with cocaine, after which anaesthesia was induced with pentothal and continued with ether and air from an "Oxford vaporizer." A wide-bore oral endotracheal tube was passed, and the space between it and the trachea occluded with the usual inflated cuff. This ensured that all the air passing in and out of the lungs was measured on a recording spirometer. The apparatus for measuring pulmonary ventilation was in charge of Dr. S. L. Cowan, D.Sc., lately physiologist to this department, and it is hoped that details will be published by him in due course. The kymographic records which we give here are of the better-

known methods of artificial respiration, and the ones which we think will be of most general interest. Subsequently the experiments were repeated on another colleague (J. R.), of about 13 st. (82.5 kg.) weight.

The subjects were deeply anaesthetized until the intercostal muscles were paralysed. At this stage slight hyperventilation resulted in respiratory arrest. Various methods of artificial respiration were carried out by the same skilled operator. The respiratory rate was kept uniform at 10 per minute.

EVE'S ROCKING STRETCHER

A SMOOTH RHYTHM D "JERRY" RHYTHM

FIG. 1

Fig. 1 shows that Eve's (1943) rocking method produces a larger tidal exchange with the subject on his face than when on his back. The reason for this is not clear. Ventilation of the lungs increases with the angle through which the subject is rocked. Fig. 2 shows the figures resulting from Schäfer's and

FIG. 2

Silvester's methods compared with those obtained from rocking the prone subject through 90°. In Fig. 3 the figures for inflation of the lungs with oxygen from an Oxford inflator (Macintosh and Pratt, 1939) give an accurate indication of the value of this method. In the "mouth-to-mouth" method the operator blew into the free end of the endotracheal tube. The term "mouth to mouth" is here, therefore, a misnomer, and the figures are

much better than those which would be obtained if actual mouth-to-mouth inflation (Elisha's method! see 2 Kings, iv. 34) were attempted.

FIG. 3

Discussion

Our figures (see Table) probably show the various methods of artificial respiration at their best. A clear airway was main-

Tidal Exchange with Various Methods of Artificial Respiration

Method	Tidal Exchange in ml.	
	E. A. P. (Wt. 10 st.)	J. R. (Wt. 13 st.)
Eve's rocking:		
On back { 60°	240	570
{ 90°	380	635
On face { 60°	340	725
{ 90°	550	850
Schäfer	340	530
Silvester	400	650
"Mouth-to-mouth" inflation	900	1,030
Oxford inflator	970	1,550

tained throughout by a wide-bore endotracheal cuff-tube. The subjects were healthy young males, and the operator highly skilled.

Eve (1943) claims that the venous return to the heart, and therefore the output from the heart, are improved more by his method than by others. The figures we give record only pulmonary ventilation.

We believe that in artificial respiration too much stress has been laid on unimportant outward details and not enough on absolute essentials such as the maintenance of a clear airway. The choice of any particular method appears to us relatively unimportant. If the subject is dead no method will be availing, and, speaking broadly, if a spark of life still exists any method, properly carried out, will probably suffice.

Waters and Bennett (1936) recorded the figures of artificial respiration carried out under deep surgical anaesthesia, and we can agree with their observation that "an apnoeic patient under deep anaesthesia stimulates the candidate for resuscitation by artificial respiration."

The report of a rural life conference held at Newbury at the beginning of the year has been issued under the title *The Science of Relationships* from C.M. House, 6, Salisbury Square, London, E.C.4, price 2s. The object of the discussion was to counteract one-sided development by fostering closer contact between workers in different callings, and to promote a unified programme of action. It was attended by people interested in medicine and nutrition, and among the papers was one by Prof. J. Scott Watson on "Agriculture, Food, and Society," which dealt with nutritional problems.

OBSERVATIONS ON NORMAL BODY TEMPERATURES IN NORTH INDIA

BY

E. T. RENBOURN, M.D., B.Sc., M.R.C.P.

Major, R.A.M.C.; Biological Research Team, India Command

WITH A STATISTICAL ANALYSIS BY

F. F. BONSALE, B.A.

Capt., R.E.

(From the User Trials Establishment, India)

The effect of hot climates on normal body temperature has for long been a controversial problem among students of climatic physiology. Castellani (1938) denies that body temperature is affected by journeys to the Tropics or residence there. Sundstroem (1927), and more recently Radsma *et al.* (1938) and Mason (1940), find a higher mean temperature of Europeans in tropical climates. The present data represent some 1,800 temperature records taken during the period March–September, 1945, in North India (Dehra Dun).

Method

In this investigation 21 ordinary clinical thermometers were used. The standard deviation for these corrected to 98.6° F. was 0.12° F.

For resting temperatures, individuals were used who were on normal military duties, had not marched during that day, and had rested for half an hour in the shade. Meals had not been taken for at least one hour. The clothing worn in all cases was khaki drill. Oral temperatures were taken (a) under the tongue with the mouth firmly closed, and (b) with the thermometer placed as far as possible into the rectum. Where oral and rectal temperatures were done on the same individual these were taken simultaneously, a period of at least three minutes being allowed. All readings were taken in the upright position. Where possible, temperatures were taken in the laboratory, otherwise in the open out of the sun. Individuals were not selected in any way, but no mechanical method of random sampling was used. All British personnel had been in the area for at least four months, and most for one to two years.

The Frequency Distribution of Resting Oral Temperatures

Table I represents the analysis of 9 groups of individuals whose oral temperatures were taken at different times of the day during the monsoon period. The frequency histograms of the groups are shown in Figs. 1 to 9. The wet- and dry-bulb readings were taken at the time of examination. The mean for the whole group of 894 individuals is 98.75° F.; standard deviation, 0.50; and S.E. mean, 0.017. The corresponding figures found by Whiting (1915–17) for 500 criminals in England were: mean, 98.38° F.; S.D., 0.486; S.E. mean, 0.011.

Examination of the skewness figures in Table I shows that some of the samples differ significantly from the normal distribution. There is, however, no evidence of skewness in the total population of temperatures. The fact is that the samples are far from being random samples. There is no evidence from the data that oral temperatures are not normally distributed.

The figures for the standard error of the mean show that the means of some of our samples vary significantly. They also show that the mean temperatures for Serials 1–5 are significantly high compared with the "normal" temperature of 98.4° F. No other meaning should be attached to the standard errors owing to the fact that our samples are not random samples from the total population of temperatures. The low mean of Serial 6 may be explained by the fact that these men were examined just after a heavy shower. This point is discussed later.

Man-to-Man and Diurnal Variation of Resting Temperatures

The first set of data considered here is quoted in full in Table II. It consists of oral and rectal temperatures of 12 normal Indian soldiers taken at five different times during the day on Aug. 8, 1945. The men belonged to one unit, experienced approximately the same external conditions during the day, and were on the same light duty.

Examination of Table II shows that the mean oral temperature for the 12 men rises steadily from 98.79° at 8.30 a.m. to 99.43° at 7.30 p.m., and the means for the individual men vary between 98.58° and 99.66° F. It is clear that the observed variation may not be entirely haphazard but may be partly due to differences

TABLE I.—Analysis of Oral Temperatures of 9 Groups taken during the Monsoon Period

Serial	Race	Sample Size	Date and Time	Dry- and Wet- bulb ° F.	Mean ° F.	Standard Deviation	Skewness (d)	Standard Error		
								Mean	S.D.	Skewness
1	Indian (Travancore)	100	29/6/45 11.15 a.m./12.15 p.m.	95/80	98.86	0.36	-0.11	0.036	0.026	0.044
2	Indian (Punjab)	108	29/6/45 3 p.m./4 p.m.	95/82	98.88	0.43	Not sig.	0.042	0.029	—
3	Gurkha	150	29/6/45 5 p.m./6 p.m.	94/80	98.92	0.49	+0.10	0.040	0.029	0.049
4	British	120	4/7/45 2 p.m./4 p.m.	95/78	98.94	0.49	Not sig.	0.045	0.032	—
5	Indian (Mixed)	105	5/7/45 2.30 p.m./4 p.m.	85/74	98.87	0.37	+0.25	0.039	0.028	0.047

8	Gurkha	70	24/7/45 8.30 a.m./9 a.m.	82/76	98.58	0.37	Not sig.	0.044	0.031	—
9	Indian (Punjab)	53	24/7/45 8.30 a.m./9 a.m.	88/72	98.45	0.43	+0.18	0.059	0.042	0.072
Total		894			98.75	0.50	Not sig.	0.017	0.012	—

NOTE.—The statistics above have been calculated from the moments of the distributions. The estimates of the standard deviation and skewness so obtained are inaccurate for small samples, but are sufficiently accurate for the samples used here.

TABLE II.—Simultaneous Oral and Rectal Temperatures (° F.) of 12 Indian Soldiers taken on Aug. 8, 1945

Man	Time								Mean	
	T1 8.30 a.m.		T2 11 a.m.		T3 2 p.m.		T4 5 p.m.		T5 7.30 p.m.	
	Oral	Rectal	Oral	Rectal	Oral	Rectal	Oral	Rectal	Oral	Rectal
M1 ..	99.4	99.8	99.0	100.0	99.0	99.6	99.2	99.8	100.0	100.2
M2 ..	98.4	99.0	98.6	99.6	98.9	—	99.2	100.0	99.0	100.0
M3 ..	99.0	99.4	99.0	99.6	99.0	99.7	99.2	100.4	99.2	100.5
M4 ..	99.4	99.6	99.5	100.6	99.3	100.0	99.5	100.5	100.6	101.0
M5 ..	98.9	99.4	98.8	100.1	99.2	100.0	99.2	100.3	99.6	100.7
M6 ..	98.2	98.4	98.6	99.4	98.6	99.4	98.4	99.4	99.2	99.8
M7 ..	98.6	(98.4)	99.0	99.6	98.8	99.8	99.0	(98.4)	99.2	99.6
M8 ..	99.0	(98.2)	98.8	100.0	98.6	99.2	99.0	99.8	99.2	100.5
M9 ..	98.2	98.8	98.4	98.8	98.7	99.0	99.0	99.4	99.6	99.6
M10 ..	99.2	99.9	98.6	100.0	99.4	100.0	99.7	100.0	99.6	100.2
M11 ..	98.5	99.2	98.9	100.0	98.8	100.3	99.2	99.8	99.4	100.6
M12 ..	98.7	99.6	98.6	99.6	99.0	100.2	98.8	99.6	99.6	100.0
Mean	98.79	99.14	98.82	99.78	98.94	99.74	99.12	99.78	99.43	100.23

NOTE.—The brackets signify that the oral temperature is above rectal.

TABLE IIA.—Simultaneous Oral and Rectal Temperatures (° F.) of 14 British Personnel taken at 5 p.m. on July 4, 1945

Man :	1	2	3	4	5	6	7	8	9	10	11	12	13	14
Oral ..	99.4	99.2	99.8	100.0	99.6	99.6	99.6	99.8	99.6	99.2	99.4	99.6	99.8	99.6
Rectal ..	101.0	101.0	100.4	100.4	100.2	100.6	100.2	100.8	100.0	100.0	101.0	100.4	100.6	100.6

between men and partly to systematic changes during the day in addition to haphazard variation.

To test this hypothesis we divide the total variance into three s: variance of man-to-man variation, time-to-time variation, and phazard or "error" variation (Table III).

TABLE III

Type of Variation	Variance	Degrees of Freedom for Estimate
Man-to-man	0.47090	11
Time-to-time	0.83933	4
Error	0.05769	44

If there is no significant variation man to man our estimate for the man-to-man variance will not differ significantly from our estimate of the error variance. The significance of the time-to-time variation is tested in the same way. The test of significance used is the Z test (Fisher and Yates's *Statistical Tables*). With this set of data we have:

(a) Man-to-Man Variation:

$$e^2z = \frac{\text{man-to-man variance}}{\text{error variance}} = 8.163, \text{ from which } p < 0.1\%.$$

The probability (p) that this value of e^2z should arise through chance is less than one in a thousand.

It is clear, therefore, that the differences between men are significant.

(b) Time-to-time Variation:

A similar calculation gives:

$$e^2z = 14.55; p < 0.1\%,$$

which shows that the differences between times are also significant.

We have thus shown that for our group of 12 men there are significant differences between men and that significant changes take place in the temperature of the group during the day. Another way of expressing this result is to say that each man has his own characteristic range of temperature and that there is a strong tendency for all the temperatures in the group to vary together. On this particular day they all tend to increase. This tendency for the temperatures of all men in the group to vary together may be explained in two ways. It may be due to some internal rhythm or, since all the men experience the same external conditions, it may be due to some change in the external conditions—for instance, the air temperature.

Rectal temperatures were taken at the same times for the same group of 12 Indian soldiers (Table II). Analysing these data in exactly the same manner gives:

TABLE IV

Type of Variation	Variance	Degrees of Freedom	Variance Ratio e^2z	p
Man-to-man	0.75433	11	5.67	<0.1%
Time-to-time	1.57063	4	11.81	<0.1%
Error	0.13303	44		

FIG. 1.—Serial 1 (Table I). Mean, 98.86°; mode, 98.97°. Significant skewness.

FIG. 2.—Serial 2. Mean, 98.88°. No significant skewness.

FIG. 3.—Serial 3. Mean, 98.92°; mode, 98.81°. Significant skewness.

FIG. 4.—Serial 4. Mean, 98.94°. No significant skewness.

FIG. 5.—Serial 5. Mean, 98.87°; mode, 98.62°. Significant skewness.

FIG. 6.—Serial 6. Mean, 98.13°; mode, 98.51°. Significant skewness.

FIG. 7.—Serial 7. This group consisted of British troops who had been two years or more in India. Mean, 98.62°. No significant skewness.

FIG. 8.—Serial 8. Mean, 98.58°. No significant skewness.

FIG. 9.—Serial 9. Mean, 98.45°; mode, 98.26°. Significant skewness.

The means for the group at the five times are:

T ₁	T ₂	T ₃	T ₄	T ₅
99.14°	99.78°	99.74°	99.78°	100.23°

The results for rectal temperatures are therefore almost exactly the same as for oral temperatures.

Correlation of Resting Oral and Rectal Temperatures

Correlating the two sets of data for oral and rectal temperatures of the same 12 Indian men used in Table II, we obtain:

Correlation coefficient $r = 0.6605$; $p < 0.1\%$.

This indicates that there is a positive and significant correlation between oral and rectal temperatures. It may be objected that this apparent correlation may be entirely due to the correlation of both oral and rectal temperatures with time. We therefore calculate the partial correlation coefficient with time eliminated:

Partial correlation coefficient $r_1 = 0.5258$; $p < 0.1\%$.

This shows that even when time is eliminated there is a positive and significant correlation of oral and rectal temperatures. If at any time, therefore, a normal man is found to have an unusually high oral temperature we may also expect with reasonable confidence to find an unusually high rectal temperature.

Some doubt is thrown on this conclusion by a second set of data. On July 4 oral temperatures of a large group of British troops were taken, and rectal temperatures of the first 14 men found to have oral temperatures over 99° F. (see Table IIA). The correlation coefficient found for this set of data is not significant. The reason for the absence of correlation in this case is probably that the sampling technique imposes too close a restriction on the variation of oral temperatures.

Another set of similar data concerns 20 normal British soldiers whose temperatures were taken four times during a day, on Aug. 24 (Table V). The analysis is given in Table VI.

TABLE V.—20 Normal British Soldiers

	Time:	9 a.m.	12.30 p.m.	2.30 p.m.	5 p.m.
Minimum oral temp.; ° F.	..	98.2	98.0	98.3	98.3
Maximum " " " "	..	99.3	98.8	100.0	100.1
Mean " " " "	..	98.82	98.43	99.015	98.93
Minimum rectal temp.; ° F.	..	99.0	98.3	99.1	98.4
Maximum " " " "	..	100.0	99.3	100.3	100.8
Mean " " " "	..	99.645	99.025	99.70	99.32

TABLE VI.—Analysis of Table V

	Type of Variation	Variance	Degrees of Freedom	Variance Ratio χ^2	p
Oral	Man-to-man	0.42986	19	5.13	<0.1%; sig.
	Time-to-time	1.33612	3	15.95	<0.1%; sig.
	Error	0.08375	57		
	Man-to-man	0.42102	19	3.63	<0.1%; sig.
Rectal	Time-to-time	1.56633	3	16.94	<0.1%; sig.
	Error	0.11613	57		

Inspection of Table VI shows that the results do not differ from those for the Indian troops:

An even higher value is found for the correlation of oral and rectal temperatures:

$$r = 0.79504; p < 0.1\%.$$

Eliminating the correlation of oral and rectal temperatures with time, we find the value of the partial correlation coefficient,

$$r_t = 0.75972; p < 0.1\%.$$

Seasonal Variation of Resting Oral Temperatures in Groups of Individuals

The oral temperatures of a number of small groups of British and Indian soldiers were taken at 10 a.m. on a number of days scattered irregularly over the period March to October. Tables VII and VIII show the results obtained:

TABLE VII.—British Troops

Month	Size of Sample	Mean (° F.)	S.E. of Mean
March	9	98.07	0.17
May	42	98.62	0.08
June/July ..	11	98.61	0.13
August/September	26	98.62	0.08
October	84	98.40	0.06

TABLE VIII.—Indian Troops

Month	Size of Sample	Mean (° F.)	S.E. of Mean
April	6	98.25	0.23
May	8	99.40	0.21
August	70	98.81	0.07
September ..	45	98.87	0.06
October	69	98.40	0.07

Tables VII and VIII show that the oral temperature taken at 10 a.m. rises in the period March to May, remains constant from May to September, and falls in September and October. The very high May figure for Indian troops is almost certainly a freak of chance due to the small size of the sample. These seasonal changes correspond closely to the changes in the 10 a.m. temperature at Dehra Dun.

Seasonal and Diurnal Variation of Resting Oral Temperature in an Individual

The oral temperatures of 7 individuals—4 British, 3 Indian—were taken at a number of fixed times during the day, and repeated on several days during the year. These data enable us to determine whether an individual has a characteristic variation in temperature during the 24 hours: is the oral temperature periodic, with a period of 24 hours? It also enables us to determine whether there is any significant seasonal change not only in the mean oral temperature but in its 24-hour variability. The method of analysis is the same as that used in Table III, except that instead of sets of data for different men we have sets of data for the same man on different days. The data from 4 of the cases are analysed below.

First Case (British)

TABLE IX.—Seasonal Variation

Date:	May 6	June 14	Aug. 5	Sept. 7
Oral temperature; ° F. ..	1.8	2.1	1.1	1.0
" " " " " " " " " "	98.2	97.91	97.34	97.85
Variance; ° F.	0.56	0.60	0.14	0.14
Mean air temperature*; ° F. ..	85.5	91	80	79.5
Range† air " " " " " "	31	26	12	15

* Mean air temperature quoted is the approximate estimate $\frac{\text{max.} + \text{min.}}{2}$.

† Range = max. — min.

TABLE X.—Diurnal Variation

Time:	7 a.m.	10 a.m.	1 p.m.	4 p.m.	7 p.m.	10 p.m.	12 p.m.	2 a.m.
Mean for 4 days; ° F.	97.23	98.33	98.18	98.18	98.43	97.88	97.43	96.98

Table IX shows that the mean oral temperature falls slightly from May to September, corresponding to the slight fall in mean air temperature. It also shows that there is a marked decrease in the variability of the oral temperature corresponding to the great decrease in air-temperature range during the monsoon period.

Table X shows that the oral temperature is periodic, with a maximum in the afternoon and a minimum in the very early morning, more or less corresponding to the 24-hour variation of air temperature.

TABLE XI.—Significance

Type of Variation	Variance	Degrees of Freedom	Variance Ratio $\frac{c^2}{c^2}$	p
Seasonal	1.03083	3	12.98	< 0.1%; sig.
Diurnal	1.200	7	15.11	< 0.1%; sig.
Error	0.07940	21		

Table XI shows that the observed seasonal and diurnal variations are significant for this individual case. If similar results are obtained from other individual cases it will be reasonable to deduce that the oral temperature is influenced to an important extent by the air temperature.

Second Case (British)

TABLE XII.—Seasonal Variation

Date:	Mar. 20	May 6	June 14	Aug. 5	Sept. 9	Sept. 23
Range oral temperature; ° F. ..	1.9	2.0	1.0	1.7	1.4	1.1
Mean oral temperature; ° F. ..	97.51	97.83	97.94	98.08	97.65	97.44
Variance	0.46	0.51	0.14	0.30	0.20	0.16
Mean air temperature; ° F. ..	67	85.5	91	80	79	78
Range air temperature; ° F. ..	28	31	26	12	18	16

TABLE XIII.—Diurnal Variation

Time:	7 a.m.	10 a.m.	1 p.m.	4 p.m.	7 p.m.	10 p.m.	12 p.m.	2 a.m.
Mean for 6 days; ° F.	97.08	97.98	97.9	98.18	98.42	97.75	97.48	97.12

TABLE XIV.—Significance

Type of Variation	Variance	Degrees of Freedom	Variance Ratio $\frac{c^2}{c^2}$	p
Seasonal	0.49576	5	6.5568	< 0.1%; sig.
Diurnal	1.39282	7	18.4211	< 0.1%; sig.
Error	0.07561	35		

Tables XII, XIII, and XIV show that the variation of the second case is substantially the same as that of the first. Two figures in Table XII are not in accordance with expectation: the low variance on June 14 and the high mean on Aug. 5. Such deviation from expectation is, however, usual in data of this sort.

Third Case (Indian)

TABLE XV.—Seasonal Variation

Date:	April 2	May 2	July 30	Sept. 27
Range oral temperature; ° F. ..	3.0	3.0	1.8	2.4
Mean " " " " " " " "	98.47	98.47	98.8	98.22
Variance	1.07	0.99	0.40	0.57
Mean air temperature; ° F. ..	75	83	79	70.5
Range " " " " " " " "	22	30	14	11

TABLE XVI.—Diurnal Variation

Time:	7 a.m.	10 a.m.	1 p.m.	4 p.m.	7 p.m.	10 p.m.
Mean for 4 days; ° F.	96.95	98.6	98.88	99.13	99.13	98.25

TABLE XVII.—Significance

Type of Variation	Variance	Degrees of Freedom	Variance Ratio $\frac{c^2}{c^2}$	p
Seasonal	0.34365	3	3.32253	< 5%; sig.
Diurnal	2.71675	5	26.26655	< 0.1%; sig.
Error	0.10343	15		

These results agree closely with expectation.

Fourth Case (British)

TABLE XVIII.—Seasonal Variation

Date:	Mar. 26	May 13	Aug. 3	Aug. 22	Sept. 9	Sept. 23
Range oral temperature: °F.	1-6	2-2	1-5	1-4	1-4	1-5
Mean oral temperature: °F.	97.94	97.83	98.21	97.66	97.53	98.27
Variance	0.33	0.89	0.29	0.24	0.23	0.32
Mean air temperature: °F.	73.5	82.5	80.5	78	79	78
Range air temperature: °F.	27	31	13	12	18	16

TABLE XIX.—Diurnal Variation

Time:	7 a.m.	10 a.m.	1 p.m.	4 p.m.	7 p.m.	10 p.m.	12 p.m.	2 a.m.
Mean for 6 days: °F.	97.33	98.38	98.52	98.67	98.6	98.12	97.7	97.27

TABLE XX.—Significance

Type of Variation	Variance	Degrees of Freedom	Variance Ratios	p
Seasonal ..	0.25684	5	3.16422	<5%; sig.
Diurnal ..	1.93857	7	23.85283	<0.1%; sig.
Error ..	0.03117	35		

The agreement with expectation of the mean oral temperatures in Table XVIII is poor. The variance figures in Table XVIII are in accordance with expectation.

Effect of Exercise on Oral and Rectal Temperatures

Data from "Clothing" Trial—Oral Temperatures

Oral and rectal temperatures of a group of 13 British men were taken on five days—D1, D2, D3, D4, D5—at 9 a.m. and 12.30 p.m. in a period of 14 days (Aug. 24–Sept. 7). D1: the men rested indoors except for a 1½-mile march before 9 a.m. D2: the men marched 10 miles between 9 a.m. and 12.30 p.m.; heavy rain. D3: the men marched 10 miles between 9 a.m. and 12.30 p.m.; heavy rain. D4: the men marched 10 miles between 9 a.m. and 12.30 p.m.; no rain. D5: the men rested indoors.

The conditions of the march were as identical as possible on each of the march days—viz., route, load carried, clothing, and rate of marching. The wet- and dry-bulb temperatures at 9 a.m. and 12.30 p.m. did not vary more than 2–4° F.

TABLE XXI.—Oral Temperatures

Day:	D1	D2	D3	D4	D5
Mean rise for fall in oral temperature, 9 a.m. to 12.30 p.m.: °F.	-0.3	-0.65	-0.31	+0.67	+0.22

The difference between these mean variations of temperature is significant ($p < 0.1\%$).

Comparing D1 and D5, we see that when the men rest indoors all day their temperature rises. When they rest after a march of only 1½ miles it falls. Comparing D4 and D5, we see that the rise in temperature is considerably greater if the men march 10 miles in dry warm conditions. A comparison of D2 and D3 with D4 shows that marching in the rain produces a fall in oral temperature instead of a rise.

It may be concluded that marching under dry warm conditions produces a rise in oral temperature but marching in the rain produces a fall. It is reasonable to deduce that exercise causes a rise in oral temperatures, while the cooling effect of rain produces a marked fall.

Data from "Clothing" Trial—Rectal Temperatures

The results are shown in Table XXII.

TABLE XXII.—Rectal Temperatures

Day:	D1	D2	D3	D4	D5
Mean rise or fall in rectal temperature, 9 a.m. to 12 noon: °F.	-0.59	+0.95	+1.0	+1.65	+0.02

The differences between the mean rises in temperature are significant ($p < 0.1\%$).

Comparing D1 and D5, it is seen that the 1½-mile march before 9 a.m. produces a fall in rectal temperature between 9 a.m. and 12.30 p.m. as compared with a completely resting day. Comparing D2, D3, and D4 with D5, we see that a march under the conditions of the experiment produces a rise in rectal temperature whatever the weather. Comparing D2 and D3 with D4, it is seen that the rise in rectal temperature produced by a march is greater on a dry day than on a wet day.

It may be concluded that marching produces a rise in rectal temperature which is larger on a dry day than on a wet day. The rectal temperature is apparently less influenced by external conditions than is the oral temperature. Results from other field trials gave similar findings.

Discussion

Table I and the histograms shown in Figs. 1 to 9 demonstrate that under the particular conditions of the investigation oral temperatures higher than those accepted as normal for temperate climates are not uncommon during the summer in North India. Most authorities accept 97–99° F. as the normal range, but it is known that figures above or below may under certain conditions be accepted as normal resting temperatures. The total range for the 894 individuals is 96.7–100.4° F., and including data from Table II this becomes 96.3–100.6° F. for the period 8.30 a.m. to 7.30 p.m. Among the British personnel no correlation could be found between length of service and resting oral temperature. In all cases examined the resting pulse rates were normal, but routine pulse rates were not recorded. No correlation was found in two groups of about 200 individuals each, one British and one Indian, between the resting oral temperature and erythrocyte sedimentation rate done at the same time. Using data obtained from troop trials, an attempt was made to correlate the resting rectal temperature with the post-exercise pulse rate and the rise in rectal temperature in groups of men doing the same work under similar conditions. Scatter diagrams did not suggest any obvious correlations.

In a group of individuals whose physical efficiency was measured at various times, using the Harvard pack test, the individual whose score was invariably the highest also showed the highest summer temperature. There are no data available yet which in terms of physical efficiency or acclimatization throw light on this climatic rise in temperature. Although there are not enough data to warrant a valid comparison between the Indian and the British personnel, it would seem that the temperatures in Indians are not much different from those of the British (Tables I, VII, VIII). It does not appear, therefore, that acclimatization in the ordinary sense is an important factor. In this respect the condition known as prickly heat is of interest. It was a common finding during the early part of the monsoon period in both British and Indian personnel, but with a lower incidence in the latter. However, in neither group was any relationship found between the presence of prickly heat and the level of the resting oral temperature.

Mason (1940) concluded that the type of body response in the heat might explain why in some individuals the temperature rose in hot climates yet did not rise in others. She found that British and American women showed two types of response in the basal metabolic rate. In the first type this fell by about 10% with no significant change in oral temperature, and in the second the basal metabolic rate was unaffected but the temperature rose significantly (average 0.6° F.). Muscular relaxation is brought about more easily in a hot environment, and the basal rate in temperate and that in hot climates are strictly not comparable. If there were two types of response to climatic heat we might expect a bimodal frequency curve. This is not suggested by our findings. Out of the 9 distributions only Serials 1 and 4 have a definite appearance of being bimodal, when grouped at 0.2° F. In both of them the modes occur at 98.4 and 99° F., and bias in favour of reading even figures on a thermometer may explain the apparent double mode. Data are not available as to the effect of a hot but very dry climate—viz., Iraq—on body temperature. It may not be the same as in North India, where low humidity is uncommon.

A point of practical importance is the clinical significance of raised body temperature in hot climates. The data in Table I were collected with the help of unit medical officers who were unaware of the fact that oral resting temperatures

in both British and Indian troops could lie between 99 and 100° F. in the summer months. A few hours' bed rest does not necessarily alter the level of the daily temperature curve, but bed rest for more than 24 hours will usually do so. It is therefore likely that an individual with what may be called climatic fever will show, when convalescing from an infective process, a recurrence of his "normal" fever after he has been up for a day or so. Unless its significance is realized the individual may be retained in hospital for further investigation. Again, a man reporting sick with an oral temperature above 99° F. may have a condition which is in no way related to his temperature. There is evidence that climatic fever may have been a cause of some man-power wastage among Army personnel.

It is usually stated in textbooks of medicine and physiology that there is a fairly constant relation between rectal and oral temperatures taken at the same time, the rectal being 0.5° to 1° F. higher. Table II_A shows that rectal temperatures of 101° F. are not uncommon in the summer. Stadler (1942) in 233 parallel determinations of resting rectal and oral temperatures of hospitalized convalescent children found differences of -1° to +3.2° F., with oral temperature higher in two cases. Carmichael and Linder (1934) in repeated parallel determinations on 24 normal individuals found differences of -1.3° to +3° F., with several cases in which the oral was higher than the rectal. In our own series of 260 simultaneous resting rectal and oral temperatures the oral was found at a higher level in three cases (Table II, figures in brackets), with a maximum rectal-oral difference of -0.8° F. It would be natural to assume that such a result is due to technical error, but it is safer to suppose that it may be real, although at present the cause is not clear. The analyses in this paper show that out of three sets of data analysed a significant correlation coefficient between oral and rectal temperature was found in two sets only. In general it may be said that at rest the oral and the rectal follow each other, but it is unsafe in any particular case to predict one from the other.

Data obtained from groups of men and from individuals studied over the period March to October suggest that a seasonal change in temperature occurs. Tables VII and VIII show that a rise of 0.5 to 0.6° F. in mean temperature may occur with the onset of hot weather, with a fall at the end of the monsoon period. Indians seem to react in a way similar to British personnel. The mean oral temperature appears to be high at seasons when the mean air temperature is high. This correlation is, however, not marked, and it is possible that the correlation is with the wet-bulb rather than the dry-bulb temperature. Again, analysis of the diurnal temperature records showed a correlation between the variation in oral temperature and the variation in the air temperature. Many factors other than meteorological are concerned in controlling the normal resting body temperature. In women there is a monthly curve temperature related to the menstrual cycle, and small changes may occur with fluctuation of endocrinal or emotional tone. One cannot therefore expect a high correlation between the body temperature and meteorological conditions. This is particularly true for the individual. The material presented here is small and many more data are required on this subject.

A point of practical interest is the maximum daily range of oral temperature. Textbooks give 1 to 1.5° F. as the normal range. Of 36 diurnal curves (7 a.m. to 2 a.m.) in 14 individuals done between March and October, 36% showed a daily range of 1 to 1.5° F., 55% showed a range of 1.6 to 2.6° F., and 9% reached a range of 3° F. The latter occurred in the months of April and May. Table XV shows a range of 3° F. in an Indian. It is sometimes stated that a hot climate does not affect the range of daily temperature but simply raises its level. The present data do not support this.

Results from the troop trials showed that a march of 3½ hours' duration during the monsoon period raised both oral and rectal temperatures, the latter about 1° F. more than the former (Tables XXI and XXII, D4). The same march done by the same men under very similar meteorological conditions but during a heavy shower showed a fall in oral temperature and a smaller rise in rectal temperature (Tables XXI and XXII, D2 and D3). Prolonged marching may on occasion produce a fall in oral temperature even in the absence of rain, but the rectal

temperature invariably shows a rise (Brennemann, 1943). The low mean resting temperature of Serial 6 (Table I) may in part be explained by exposure to rain before temperatures were taken. Cooling of the mouth by the increased respiration due to exertion is not sufficient to explain this phenomenon. It is possible that in conditions where the skin is being rapidly cooled by sweating, air currents, or rain the temperature of the oral cavity tends to follow the skin temperature rather than the internal temperature. Reflex vasomotor phenomena involving the mouth and the neighbouring skin may play a part. The oral temperature cannot be regarded as an accurate index of the internal body temperature, particularly in conditions of activity, and is more affected by external conditions than is the rectal temperature.

Conclusions

Using ordinary clinical thermometers, oral and rectal temperatures of both Indian and British troops during the summer months in North India show levels above those accepted as normal for temperate climates. Oral temperatures up to 100.6° F. and rectal temperatures up to 101° F. may occur in apparently normal individuals. The distribution curve of 894 cases is not significantly skewed.

An individual tends to have his own characteristic daily temperature curve, and on a particular day a group of individuals behave in the same way as regards oral and rectal temperatures.

A significant correlation coefficient is not always found between resting oral and rectal temperatures. In a very small percentage of cases the oral temperature may be actually above the rectal.

Analysis of groups of men and several individuals, both British and Indian, suggests a seasonal trend in the mean oral temperature, which tends to follow the range of air temperature.

Exercise in the rain may cause a fall in the oral temperature. For many physiological conditions the oral temperature may not be a good index of the internal temperature.

RESULTS OF MASS RADIOGRAPHY OF R.A.F. EX-PRISONERS-OF-WAR FROM GERMANY

BY

A. G. EVANS, M.R.C.S., L.R.C.P.

Squadron Leader, R.A.F.V.R.; Assistant Tuberculosis Officer, Warwickshire and Coventry Joint Committee for Tuberculosis

It was realized that at the termination of hostilities with Germany a considerable number of Air Force personnel would be returning to this country from captivity. A decision was therefore made by the Air Ministry that a Mass Radiography Unit should be installed at the reception camp in the Midlands to which they would return.

All personnel who were fit to travel were brought here for preliminary medical examination and radiography of the chest before going on leave. It should be pointed out, however, that a certain number of cases required direct admission to hospital and were unfit to travel. These cases are not included in our mass radiography figures. It was the policy, so far as was possible, to allow the men first to proceed on leave, then undergo a complete investigation of their pulmonary abnormalities on return. Although there was a certain amount of risk in this, it was considered that, from the point of view of morale, they would respond far more favourably to investigation and treatment when they had seen those from whom they had been separated so long.

Upon return from leave the ex-prisoners selected from the miniature films were re-x-rayed on large films and those requiring further investigation admitted to the local regional R.A.F.

hospital. Here at least six sputum tests were performed, and, if negative, a further three examinations of the gastric washings were made; temperature observations, B.S.R., and exercise tolerance tests were also performed. The final disposal was decided by the medical officer in charge of the chest radiography section. Each man was interviewed, together with the medical specialist responsible for the hospital beds, and his future prospects and plans considered before the final recommendation was made.

Broadly speaking, there were three main avenues through which personnel with tuberculous infiltration might pass. First, they might be transferred to an R.A.F. treatment centre; secondly, they might be invalided from the Service and discharged to the care of their local tuberculosis officer; or, thirdly, if the lesion was of a very minor nature they might be retained in the Service in a lower medical category or released if they had this option. Non-tuberculous abnormalities which might require surgical intervention were transferred to the R.A.F. Unit of Thoracic Surgery at Midhurst.

The total number of ex-prisoners-of-war from Germany who passed through this unit was 9,142. Among these the following abnormalities were discovered in their respective age groups (Tables I and II).

TABLE I.—Non-tuberculous Abnormalities

Disease	Age Group (Years)						Total
	20-24	25-29	30-34	35-39	40-44	45 and Over	
Bronchitis and emphysema	0	2	0	0	0	0	2
Bronchitis and emphysema with bronchiectasis	0	1	0	0	0	0	1
Pulmonary fibrosis (non-tuberculous)	4	2	2	2	0	0	10
Congenital abnormalities, p. l. monary (azygos vein, lobe, etc.)	6	3	1	0	0	0	10
Congenital abnormalities non-pulmonary	32	18	6	2	0	0	58
Acquired cardiovascular lesions	1	1	1	0	0	0	3
Thickened pleura	18	15	7	2	1	0	43
Aberrant pneumonic consolidation	9	3	4	1	0	0	17
Shrapnel in chest wall and lung fields	6	6	2	0	0	0	14

It was found that in many cases the aberrant pneumonic consolidations had resolved upon return from leave or did so after a short stay in hospital. Cases of shrapnel in the lung fields were nearly all without symptoms and did not require surgical intervention. Two of these were cases of bullets in the lung fields. All cases were referred to a surgical specialist before the final decision was reached. The numbers of other pathological non-tuberculous abnormalities are small, as might be expected in the relatively youthful age groups examined, and do not call for any special comment.

TABLE II.—Tuberculous Abnormalities Discovered

Age Group:	20-24	25-29	30-34	35-39	40-44	45 and Over	Total
Active pulmonary tuberculosis (sputum-positive)	13	3	3	0	0	0	19
Active pulmonary tuberculosis (sputum-negative)	17	6	5	0	0	0	28
Inactive pulmonary tuberculosis	15	21	25	3	0	0	64
Calcified nodule only	22	21	11	2	1	0	59
Calcified hilar glands	12	6	5	4	0	0	27
Calcified nodule and glands	20	16	10	2	2	1	51

It will be seen that there were 47 cases of active tuberculous infiltration (0.5% of the total x-rayed). This is a considerable increase over the proportion discovered in other surveys, which has remained fairly constant at 0.3% (Evans, 1943; Trail *et al.*, 1944; Dick, 1945). The majority of personnel examined were between the ages of 20 and 34. From the figures it can be seen that 64% of the active infiltrations, both sputum-positive and sputum-negative, were in the 20-24 age group; whereas 44% of the inactive infiltrations, which did not require treatment, were in the 30-34 group. Of the active infiltration cases 41 were transferred to an R.A.F. treatment centre in the north-west of England. As sufficient time has elapsed, these cases have been followed up to find out how they responded to treatment. It will be seen that the number of cases with positive

sputum has increased from 19 to 27; this is accounted for by the fact that further sputum tests are performed on arrival, including sputum culture and culture of the gastric juice for *M. tuberculosis*.

TABLE III.—Summary of the Results of Treatment

Extent of Disease	Sputum-positive	Successful A.P. Induction	Unsuccessful A.P. Induction	Conservative Sanatorium Treatment	Discharge to T.O.
Unilateral (22 cases)	15	9	3	4	6
Bilateral (19 cases)	12*	3	4	7	5

* Add one case in which the pleural fluid was positive (-).

It will be seen that 12 successful artificial pneumothorax inductions were performed out of a total of 19 attempted. In addition 11 cases were well enough to be discharged to the care of their local tuberculosis officer after a further period of observation.

Comment

The figures and results testify to the value of mass radiography. In the active infiltrations the high proportion of sputum-positive cases (57%) shows the urgency for treatment.

It must be borne in mind that a large percentage of aircrew personnel were drawn from middle-class families, and therefore the higher incidence of active phthisis requires some comment.

On questioning the men it was found that the food had been adequate until the last six months, when Red Cross parcels ceased to arrive. Most of the men had been interned for a period ranging from one to four years. One is therefore led to the conclusion that higher incidence of infection may be associated with close living quarters and a lowered resistance—in the first instance due to mental stress and in the later stages actual malnutrition.

The Royal Air Force practice of admitting to hospital for investigation before transfer to a treatment centre might well be employed as a model for civilian mass radiography. If a certain number of general hospital beds were placed at the disposal of the physician in charge of the mass radiography unit for preliminary investigation, this would avoid the stigma of attendance at tuberculosis dispensary and sanatorium, which is bound to be present under the existing nomenclature.

I should like to thank the Director-General of Medical Services in the Royal Air Force for permission to publish this paper; and also Wing Commander C. E. H. Anson and Squadron Leader C. Bremer for their help in compiling the figures.

GAS GANGRENE OF THE GALL-BLADDER

BY

W. R. S. HUTCHINSON, F.R.C.S.

Assistant Surgeon, Royal Hospital, Wolverhampton

Gas gangrene of the gall-bladder is so rarely encountered that a short detail of the circumstances attending this case may not be unacceptable.

Case Report

A man aged 56 was admitted to the Royal Hospital, Wolverhampton, on Jan. 9, 1942, having suffered with severe abdominal pain for three days. The pain was confined to the right hypochondrium. Acute and colicky at the onset, it had suddenly assumed a fearful intensity some twenty hours before admission. He had not vomited. There was no history of previous abdominal pain, indigestion, or jaundice.

On examination the patient, an obese strongly built man, was in great pain and distress. The tongue was dry and furred, temperature 98°F. (36.7°C.), pulse rate 116. Respirations were short, "grunting," and obviously painful. The abdomen was slightly distended and immobile, with extreme tenderness and rigidity in the right hypochondrium. Examination of the heart and lungs was negative, except for poor air entry at the right lung base.

A provisional diagnosis of acute cholecystitis was made, but the possibility of perforated duodenal ulcer was seriously considered. Since, however, immediate operation was obviously necessary, a

skigram of the abdomen was omitted. This proved unfortunate, as an interesting pneumogram of the gall-bladder might have been obtained.

Operation.—Under spinal analgesia the abdomen was opened by a right paramedian incision. The peritoneal cavity contained a considerable quantity of foul-smelling thin brown fluid, quite unlike the usual turbid effusion of spreading peritonitis. The gall-bladder was lightly sealed off by omentum, but on exposure was found to be grossly distended, oedematous, and haemorrhagic, the greater part of the fundus being frankly gangrenous. An attempt to aspirate the contents of the gall-bladder with a syringe yielded nothing but gas, and the distended organ immediately collapsed. Two small stones could be felt in the cystic duct, but below this the duct was healthy and of very small calibre, so that cholecystectomy was easily performed. The common bile duct was apparently normal and was not opened. The wound was closed in the usual way with a drainage-tube to the gall-bladder bed.

On examination the gall-bladder contained practically no fluid. The whole mucous membrane was necrotic, shaggy, and of a dark-brown colour. Two small calculi impacted in the cystic duct sharply limited the inflammatory process. No other stones were present. Cultures of the mucous membrane of the gall-bladder yielded a pure profuse growth of *Cl. welchii*.

Progress.—The patient was given 20,000 units of polyvalent anti-gas-gangrene serum intramuscularly at the close of the operation, and during the first three post-operative days he received a total of 20 g. of sulphapyridine. His condition remained critical for the first few days. The abdomen became very distended, and brown discoloration of the skin, characteristic of clostridial infection, gradually spread from the wound over the anterior abdominal wall. No gangrene developed, however, and both distension and staining gradually subsided. The drainage-tube was shortened after 48 hours and removed at the end of a week. Profuse purulent discharge from the track persisted for several days, after which convalescence was uneventful.

Discussion

It is now well recognized that anaerobic bacilli frequently gain access to the biliary tract. Fulminating gas gangrene of the liver, following cholecystectomy, occasionally provides an unwelcome reminder of their presence. Gordon-Taylor and Whitby (1930), using anaerobic cultures, recovered *Cl. welchii* from the gall-bladder in nearly 9% of a series of 50 consecutive cholecystectomy specimens. They also found the organisms in 13% of the gall-stones obtained post mortem. Nevertheless, gangrenous cholecystitis due to *Cl. welchii* is seldom encountered, and detailed clinical accounts of frankly gangrenous gall-bladders are very rare indeed. Vest (1933), reviewing the role of clostridia in cholecystitis, found only five such cases in the literature. Gordon-Taylor and Whitby mentioned two others, while Simon (1932) reported an interesting case in which the diagnosis was made radiologically before operation, the shadow of the gas-filled gall-bladder being clearly visible.

On the assumption that bacterial infection is the primary factor in cholecystitis and gall-stone formation, discussions of *Cl. welchii* infection in the past have been focused on the question whether these organisms are the primary cause of the disease or mere secondary invaders. But the infective theory of gall-stone formation has recently been challenged, and there is now a growing body of opinion, strongly supported by surgical experience, that bacterial infection of the gall-bladder is nearly always a secondary phenomenon, determined by the effects of gall-stones. This sequence of events is probably true of most cases, but is particularly well shown in acute cholecystitis. This disease usually begins with an attack of gall-stone colic, but, should the stone become firmly impacted, the resulting congestion and oedema of the gall-bladder, together with stasis of its contents, soon prepare the field for infection by intestinal organisms. Such we believe to have been the sequence of events in the case here recorded. The initial obstruction of the gall-bladder by stone, and its subsequent invasion by this grave disease, seem to be clearly reflected in the clinical features of the case.

Medical Memoranda

A Case of Concurrent Herpes Zoster and Varicella

The following report of a case in an elderly man seems worthy of record.

A well-preserved man aged 70 was admitted on Nov. 20, 1945, with a vesicular eruption limited to the area supplied by the right supraorbital nerve. The early history was vague, but the eruption had appeared on Nov. 17. Some of the vesicles were confluent and rapidly became haemorrhagic. On Nov. 23 he ran a temperature of 99.2° F. (37.3° C.), and next day there appeared a typical varicella eruption of a very discrete type covering the body and limbs. He has never had chickenpox, so far as he knows, nor has he recently been in contact with it or with herpes zoster.

Up to the time of writing the varicella has progressed satisfactorily, there now remaining only a few dried-up vesicles. Unfortunately the herpes zoster became infected, though it is now steadily healing.

Similar cases have been reported. J. J. Manning (1944) attended a man of 63 years with both conditions strictly concurrent, and Rose (1944) a man aged 81, the varicella developing one week after the herpes zoster. In Norman Flower's (1944) case in a man aged 40 varicella followed 11 days later. Dr. Alexander (1944) reports a case similar to my own, the varicella developing some 48 hours later; and Dr. Mary Barrow (1944) records one in which the varicella was some five days in appearing. Lastly, Dr. Simon (1944) reported a case in a man aged 63, with varicella developing five days later.

All the cases referred to were in males in the region of 60 or over, with the exception of Dr. Flower's case. The interval between the development of the herpes zoster and the appearance of the varicella varies from 48 hours to 1 week. In one case only was there a possible history of contact, but the histories in every instance were not complete.

One other case of interest was reported in the same period—namely, that of Dr. Allen (1944), the case being that of a boy aged 5½. Here the varicella preceded the herpetic eruption some three weeks.

I wish to thank Dr. J. Grant, M.O.H., Gateshead, for seeing the case and for permission to publish.

GEORGE AUSTIN SHARPE, M.B., B.S.
Medical Officer, Bensham General
Hospital.

Gateshead.

A Case of Secondary Abdominal Pregnancy

The following case history of a somewhat rare condition may prove of interest.

CASE HISTORY

A rather slim Mongo (Bantu) negress, aged about 30, of average height, was admitted to our bush hospital on Sept. 28, 1945. She had attended three months previously and was diagnosed as being five months pregnant, but no vaginal examination had been made. It was her first pregnancy. She was admitted to the labour ward by the head orderly about midday and said that "pains" had started the previous day. At 5 p.m. the orderly reported the case and said there was no progress. She was seen shortly after that time by me.

On examination the pulse was 112, of fairly good volume, and the patient, though not distressed, seemed to be in pain. There were no contractions. Heart and lungs were normal. The abdomen was enlarged to the size of an eight-months pregnancy. The foetal parts were very superficial and the outline of a bone (probably the right tibia) could be distinctly felt through the abdominal wall above and to the left of the umbilicus. There was a curious "tenseness" about the abdomen—not that associated with uterine contractions, but rather like a large fairly soft ovarian cyst. The child was lying obliquely with the back to the right and the head in the left iliac fossa. No foetal heart sounds could be heard and no souffle. Patient affirmed that there had been quite violent movements during the day. Per vaginam, there was no cervical dilatation and the characteristic softening associated with advanced pregnancy was almost completely absent. There was no haemorrhage or macroscopic discharge. Secondary abdominal pregnancy was suspected.

Operation.—At 6.30 p.m. spinal analgesia (stovaine) was given, supplemented after three-quarters of an hour by open ether. On opening the abdomen by a right paramedian incision the greenish amniotic sac was immediately apparent; it was slightly adherent to the parietes. The sac was incised; the quantity of fluid was rather less than usual. The child, a male, was extracted, and it made a few feeble movements. It weighed 2.3 kg. (just over 5 lb.). The head was flattened from side to side and especially in the right parietal

The Ministry of Education has sent to local education authorities a memorandum (No. 156, May 27, 1946) on the administration of Section 54 of the Education Act, 1944, which deals with power to ensure cleanliness in schools and school-children.

region, which had rested on the left ilium. The membranes were stripped as far as the placental edge. The placenta filled the right iliac fossa and was adherent to two loops of small gut, the top of the uterus, and several other structures. Anatomical relations were difficult to determine—e.g., the right ovary was not seen at all. There was a liberal blood supply from the omentum and also from the left ovarian vessels. Although the placental mass was slightly mobile it was with considerable apprehension that we began its removal. The ovarian vessels were first ligated; then two fingers could be passed—one in front of and the other behind the fundus of the uterus; these controlled the large vessels therein while a wedge-shaped resection was performed. The placenta was then peeled off from its remaining attachments and about 20 bleeding points ligated, the rest being controlled by hot swabs. The haemorrhage, though considerable, was not alarming. The abdomen was closed and drainage provided. There was considerable sero-sanguineous discharge for 24 hours, after which time the tube was removed. A five-day course of sulphathiazole was started. The white staff of two had to leave on the third day after the operation, but on return 14 days later they found that the patient had made a good recovery. There is a palpable mass in the right iliac fossa, presumably organizing blood-clot, but she feels well and does not complain of pain.

COMMENT

This is the second case of this rather rare condition observed here within the last five years. The first was published in the *Journal of Obstetrics and Gynaecology of the British Empire* in August, 1942. Our hospital serves at the most some 50,000 people. The number of pregnant women seen here per year rarely exceeds 200. Ectopic cases are rare—not more than two a year. The last case—March, 1945—was of ectopic twins, of 4 months. One amniotic sac was already ruptured and the foetus dead; the other sac was intact and contained a live foetus. Unfortunately we lost this case. To have two cases of secondary abdominal pregnancy in such a limited area and in such a short time is at least remarkable. The question seems naturally to arise as to whether the amniotic sac of the negress is more resistant to rupture than that of the European. The negress certainly has much less chance of getting an ectopic pregnancy diagnosed than has a European; so the African ectopic case must frequently either develop or die. There is a very high incidence of gonococcal infection amongst the Mongo tribe, which undoubtedly contributes to ectopic gestation.

Barina/Mariaga, Haut Congo Belge.

E. R. WIDE, M.D.

Cavernous Sinus Thrombosis treated with Penicillin

The following case may be of interest. An important feature is that the usual dosage of penicillin given (18,000 units 3-hourly) was found inadequate, and the dosage of 35,000 units 3-hourly was effective in treating the condition.

The patient, Mrs. B., walked into the casualty department at the Bristol Eye Hospital at 10 p.m. on Nov. 29, 1945, having been sent by her own doctor. She complained of swelling of both eyes and gave a history that one week before her admission she developed pains in the back and legs. "Sores" on her lips then appeared. Six days before admission her eyes became "swollen"; she consulted a doctor and was given drops to instil. On Nov. 25 the eyes became worse and the patient was given tablets to take. By the 29th there was no improvement, and she was sent to Bristol Eye Hospital.

On examination both eyes were found to be proptosed and the lids and conjunctivae inflamed and oedematous. The patient's temperature was 99° F. (37.2° C.), pulse 80, and respirations 20. Investigation of the fundi showed only that the veins were slightly engorged. Vision: right eye, 6/12; left eye, 6/6. Nothing abnormal was found in the heart, lungs, or kidneys. Blood pressure, 130/90. Urine: Specific gravity, 1002; reaction alkaline; N.A.D.

A diagnosis of cavernous sinus thrombosis was made, and systemic penicillin treatment was started intravenously 18,000 units 3-hourly. The patient was started on a course of sulphathiazole next day. Her condition remained stationary until Dec. 2, when there was a slight but definite improvement. Next day the improvement was more pronounced; there was less inflammation of the lids, and the eyes were less proptosed. On Dec. 5 the condition of the eyes was less favourable: both were proptosed to their original extent. On Dec. 6 penicillin was given in doses of 25,000 units 3-hourly for 24 hours, then 30,000 units 3-hourly for 24 hours, and finally 35,000 units 3-hourly until Dec. 11. The patient received in all 2½ million units of penicillin.

On Dec. 7 a marked improvement occurred, and by the 9th the eyes appeared normal and the temperature remained at a normal level, having previously fluctuated between 98° F. (36.7° C.) and 100° F. (37.8° C.). Steady improvement was maintained after this date, and uneventful recovery occurred, the patient being discharged on Dec. 22.

My thanks are due to Mr. E. R. Chambers for permission to publish the case and to Mr. J. Donaldson for his help on the question of penicillin dosage.

IRENE D. R. GREGORY, M.B., Ch.B.,
House-surgeon, Bristol Eye Hospital.

Reviews

CLINICAL PARASITOLOGY

Clinical Parasitology. By Charles Franklin Craig, M.D., and Ernest Carroll Faust, Ph.D. Fourth edition. (Pp. 871 + 355 engravings and 4 colour plates. 50s.) London: Henry Kimpton, 1945.

This is a most excellent book with which it is difficult to find any fault. In it the medical man will discover practically everything he needs to know about the animal parasites of man and much more besides. Everyone who has to deal with human disease caused by animal parasites and their vectors should possess a copy at his right hand. He will find that he is constantly consulting it, and will be rewarded by obtaining all the information he requires. The new fourth edition, which appears two years after the third, is larger by over a hundred pages. It has been thoroughly revised and much new information, the outcome of war experience, has been incorporated. Certain sections dealing with subjects of a general nature have been extended into separate chapters, as, for instance, that on scientific nomenclature, which now includes a digest of the international rules of nomenclature. Under malaria the new knowledge of the suppressive action of mepacrine is fully dealt with, while in the section on mosquito control the effectiveness of D.D.T. and of the new repellants which are products of the war is carefully considered. Much new information will be found in a considerably extended section devoted to arthropods responsible for human disease. Here all diseases, whether animal or not, are discussed in connexion with each individual transmitting agent. It is clear that the claim made that the fourth edition is thoroughly revised is amply justified, and it can be recommended as a comprehensive treatise on clinical parasitology.

SCIATICA AND INTERVERTEBRAL DISK LESIONS

Sciatiques et Lombalgies par Hernie Postérieure des Disques Intervertebraux. By P. Petit-Dutaillis and S. De Séze. (Pp. 180; illustrated. 235 francs.) Paris: Masson et Cie. 1945.

The recognition in 1911 of the relation of injury of intervertebral disks to intraspinal pressure symptoms we owe to Middleton and Teacher in Scotland, and Goldthwaite in the United States. It was, however, more than twenty years before the full significance of intervertebral disk lesions as common causes for sciatica was appreciated, notably by Barr and Mixter in 1933. The extraordinary thing is that in the French literature in the intervening years there were numerous studies of the anatomy and pathology of the disks in relation to intraspinal lesions, but, as the present authors confess, they were largely in relation to what were regarded as tumours of the disk with particular reference to the cauda equina. Nevertheless Petit-Dutaillis himself with Alajouanine in 1930 were probably the first authors clearly to recognize that these "tumours" were in fact herniations of the intervertebral nucleus. Despite further large additions to the French literature it appears that not until 1940 was there any considerable writing on the surgery of these lesions in cases of sciatica, whereas in the same year Love in America had been able to report on 500 cases operated on within the previous seven years.

The present work provides a valuable review, more particularly of French work on this subject, with extremely well set out and illustrated sections on the pathological anatomy, radiology, diagnosis, and operative treatment. In radiology in France lipiodol appears still to be freely employed, contrary to the growing practice of American and British surgeons, who depend more on clinical analysis. In this book there is a striking lack of recognition of British work. The French neurosurgeons, like their colleagues in other countries, tend to dismiss very lightly the methods of conservative orthopaedics. The impression of the reviewer is that the indications for operative intervention need much closer narrowing down, and that few cases should be operated on without prior orthopaedic consultation and co-operation.

ANATOMY AND PHYSIOLOGY FOR NURSES

The Nurse's Textbook of Anatomy and Physiology. By A. M. Spencer, M.B., Ch.B. (Pp. 288; illustrated. 8s. 6d.) London: Faber and Faber.

Anatomy and Physiology for Nurses. By J. L. Hamilton-Paterson, M.D. (Pp. 174; 102 illustrations. 9s.) London: H. K. Lewis and Co.

The demand for small works on anatomy and physiology which are suitable for nurses preparing for the Preliminary State Examination is evidenced by the recent appearance of two new elementary textbooks. Since certain points are common to both these works it will be convenient to mention these before reviewing each book separately. Each author has attempted to condense in one small volume a simple outline, in not too technical language, of these two extensive subjects; and each also gives the reader examples of the type of questions asked in previous examinations, with suggestions as to the method of answering them. No chemical formulae are used for the explanation of such processes as digestion, respiration, or general metabolism, and terms such as "breaking down" and "building up" are used for this purpose.

Dr. Spencer's book begins with a "Prologue," in which suggestions are made as to method in study—e.g., copying of illustrations, combined study with one or two fellow probationers, and practice in replying to examination questions by the study of model answers, with emphasis on the more important parts. The main body of the book is divided into seven parts, dealing with the structure and functions of the various parts and systems of the body, and the last of these sections contains an "Epilogue" giving advice about the answering of questions when actually in the examination room, the candidate being assured that her study is "complete." The illustrations vary in quality: those drawn by anatomical artists, some of which are reproduced from well-known standard works, are excellent; while some, more especially those of a diagrammatic nature, are capable of improvement, and would be better replaced in future editions by semi-diagrammatic figures founded on actual specimens. But, considered as a whole, *The Nurse's Textbook* well fulfils the purpose of the author in supplying the information required for this examination in an attractive and easily understood language which, if the directions suggested in the text are carried out, will be of great assistance to candidates for the examination and a practical help in understanding the principles on which the structure and functions of the body are founded.

Dr. Hamilton-Paterson states in the preface to his book that he fully realizes the difficulties that a nurse is confronted with in acquiring a working knowledge of anatomy and physiology, as contrasted with the medical student—the nurse having usually only a very limited knowledge of biology, and none of Latin and Greek; also, no access to a dissecting room or physiological laboratory. To meet the lack of knowledge of Latin and Greek a glossary has been appended. The first chapters deal with the tissues of the body and the various systems, whereas the remaining chapters are devoted to regional anatomy. In general, the functions of the organs and systems are described, along with their histological structure—thus the "clotting of blood" and "blood groups" after the description of blood corpuscles and plasma; and the "regulation of heat" along with the structure of the skin and sweat glands. The illustrations are for the most part good; some of the diagrammatic figures, however, overstep the limits of simplification to such an extent that they are misleading. Thus, in Fig. 10, which illustrates the difference in form of a muscle when contracted and relaxed, a muscle is shown resembling the biceps of the arm, with its tendon of origin lying in the intertubercular groove of the humerus, but with its tendon of insertion attached to the coronoid process of the *ulna*. The distal end of the *ulna* has been rotated laterally, while its proximal end, carrying the lower end of the humerus with it, has produced a twist in the longitudinal axis of this bone at its lower end, so that the medial condyle is directed forward. Similar faults appear in diagrammatic drawings (Figs. 16 and 17) or the naming of parts (Figs. 80, 87, 91), and a considerable number are present in the text. The book, however, fulfils its purpose of selecting for the reader the essential points in anatomy and physiology, thus saving the candidate the task of doing this for herself.

ELECTROCARDIOGRAPHY

A Primer of Electrocardiography. By George Burch, M.D., F.A.C.P., and Travis Winsor, M.D. (Pp. 215; 235 engravings. 18s.) London: Henry Kimpton.

As one of the first textbooks on electrocardiography to be published since the war, this primer by Burch and Winsor is of special interest. There can be few departments of medicine to which research has brought greater increases in precision in the past two decades. Not only has the response of the heart to almost every infection and disorder of metabolism been observed, but intensive study of precordial leads in conjunction with the conventional leads has given the physician a deeper insight into the location and extent of myocardial lesions. The evolution of these advances has been traced in the chapters of this very readable work. The theory of electrocardiography and the first principles on which it is based are lucidly explained with the help of numerous schematic illustrations. These latter (235 in all) constitute a special feature of the book, and are employed with great effect also in the chapters dealing with the precordial leads and the clinical applications of the electrocardiogram. Reproductions of electrocardiograms are not included; while drawings are perhaps equally explanatory, the lack of photographs tends to deprive the subject of clinical reality.

The authors emphasize in their monograph two axioms of clinical electrocardiography. The first is that the electrocardiogram without the entire clinical data is rarely of great value; a corollary might be added that an electrocardiogram may be dangerous both diagnostically and prognostically when unaccompanied by clinical data. The second axiom is that a cardiac study without an electrocardiogram is not complete or thorough. To this one might add that there can be no clinician of experience who has not at times been astonished at the revelations of cardiography in a patient previously considered to be free from cardiovascular disease. This work, which correlates so successfully and soundly the various cardiopathies and their electrocardiographic counterparts, merits the attention of all clinicians who wish to keep in touch with the trends of cardiology and clinical medicine.

Notes on Books

The H. K. Lewis corner in Gower Street, close to the University of London, is an attractive spot for the medical student of whatever age, but not everybody is aware that it boasts a hundred years' history. In 1844 a young man named Henry King Lewis, who had been an apprentice in the book trade at Windsor, opened a book-selling and stationery business in Gower Street, and to this was added presently a circulating library of medical and surgical books and a publishing house. A well-produced booklet, *Lewis's, 1844-1944* has been issued to commemorate the centenary of the firm. It gives many interesting glimpses of medical authors and others of a past generation—of the magnanimity of Osler, for example, when, by the only mischance of the kind in the history of the firm, the printers had lost a statistical table which should have accompanied one of his monographs; or of the trepidation of a student named Thomas Barlow when returning to the library a borrowed book which had been accidentally damaged. Many famous personalities in medicine appear in this booklet, all of them seen from the point of view of the publisher, but in this instance a very friendly and appreciative one. Alike in its buildings, the works it has issued, and its contacts with the medical profession, Lewis's has gradually extended, always in harmony with its high traditions, until as one visitor said, "This is more like an institution than a shop." This little biography of a business is well written and illustrated, and copies may be had free on application to 136, Gower Street, W.C.1.

Ocular Prosthesis, by J. H. PRINCE, F.B.O.A. (Edinburgh: E. and S. Livingstone; 17s. 6d.), is a readable account of the history and present status of the manufacture of artificial eyes. The fitting of artificial eyes is considered on physiological principles, and there is a useful chapter on the anatomy and physiology of the lid and orbit bearing on this. The account given of the use of plastics for the manufacture of artificial eyes is helpful. This volume is, however, unlikely to make it possible for every optician to prepare artificial eyes—a claim implied in the text—but it should form a useful guide to current teaching and practice.

The National Institute for the Deaf has issued from 105, Gower Street, W.C.1, at the price of 6d., No. 1 of a small monthly periodical *The Silent World*. Its contents include the first part of an article on the prevention of deafness by Mr. Arthur G. Wells.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JUNE 15 1946

MORE ABOUT PALUDRINE

We print in this issue an article by Prof. B. G. Macgrath which describes some of the recent results of work on paludrine, the chemistry of which was the subject of an annotation in the *Journal* of May 18 (p. 767). Paludrine belongs to an entirely new chemical series of anti-malarials (biguanides) and is the final product of a long and skilfully planned investigation which began with the study of the antimalarial properties of pyrimidine derivatives.^{1,2} In this respect alone the drug represents an important advance in the field of synthetic antimalarials. In addition, however, paludrine and its immediate predecessor, 4430, have been shown to possess the unique property of affecting the exo-erythrocytic phase of *P. gallinaceum* infection in chicks. No previous antimalarial drug has shown similar activity. The importance of this observation lies in its possible application to human malaria, since it is likely that the phenomenon of "relapsing" which is seen so commonly in human malaria, particularly in *P. vivax* infections, may be dependent upon the existence in the human tissues of a phase of the human malaria parasite corresponding to the exo-erythrocytic phase in avian malaria.³ It was hoped, therefore, that paludrine might exert in human malaria a similar effect to its activity in *P. gallinaceum*. In January, 1945, it was first tried in cases of human malaria,⁴ and immediately proved itself a remarkably efficient agent in dealing with the acute attack in both *P. vivax* and *P. falciparum* infections. Its therapeutic range was found to be much wider than that of either quinine or mepacrine, and within these wide limits it has proved practically non-toxic; side-effects in the form of mild nausea and occasional vomiting have been observed only after dosage of a gramme or more per day. At first the dosage used was a twice-daily course, which was continued for 14 days, successful termination of the acute attack being obtained in *P. vivax* infections with doses of 10 to 750 mg. and in *P. falciparum* infections with doses of 50 mg. or more twice daily. The Liverpool workers, Macgrath and Adams, and others, have now demonstrated, in agreement with Fairley's observations in sporozoite-induced malaria,⁵ that acute attacks of benign tertian malaria can be terminated by the administration of a single dose of paludrine ranging from 50 to 400 mg. Cases so treated subsequently relapse in three weeks or longer if

given no further treatment. Large single doses of mepacrine will also effect similar termination of acute attacks of benign tertian malaria.

Although paludrine has been shown to have such activity against the acute attack of malaria, the results of treatment in *P. vivax* malaria, so far as the subsequent relapse rate is concerned, have unfortunately not been so encouraging. In naturally acquired benign tertian malaria relapse has been found to occur after both 50 and 500 mg. given twice daily for a fortnight. In these dosages, therefore, paludrine is not successful in dealing with the problem of the relapse in established *P. vivax* infections. It is possible that better results may be obtained by the technique of dosages now being used by the Liverpool workers. Their results so far indicate that the administration of a single dose of 100 mg. of paludrine at weekly intervals after an initial single therapeutic dose will suppress relapses so long as the weekly dose is sustained. Whether such a course of treatment extended over a period of months will eventually cure *P. vivax* infections is not yet known. Paludrine seems to be more successful in eradicating *P. falciparum* infections.

The early work on paludrine has recently been confirmed and extended in the field. Fairley and his co-workers⁶ in Australia have issued a preliminary report on the results of extensive experiments on the activity of paludrine given to volunteers exposed to mosquitoes infected with New Guinea strains of *P. vivax* and *P. falciparum*. They have found that paludrine is an effective suppressive for both these kinds of malaria. In the case of *P. falciparum* infections their results indicate that the drug acts as a true causal prophylactic. In some volunteers, but not in all, true causal prophylaxis is also indicated in *P. vivax* infections. Fairley concludes from his experiments that in this respect "paludrine has proved superior to all known antimalarial drugs, as in non-toxic doses it is a true causal prophylactic, exerting a powerful lethal effect on the exo-erythrocytic (presumptive exo-erythrocytic) forms of *P. falciparum* and fully protecting volunteers receiving viable sporozoites by mosquito inoculation. In *P. vivax* sporozoite-induced infections it is only a partial causal prophylactic; the exo-erythrocytic (presumptive exo-erythrocytic) forms are inhibited, but eradication does not regularly occur. The only other drug which has a similar action is plasmoquin, but this drug has to be given in a dosage which is too dangerous for routine use in man."

The Australian workers have confirmed the therapeutic activity of paludrine in acute attacks of *P. vivax*, *P. falciparum*, and *P. malariae* malaria in both induced (sporozoite and trophozoite) and naturally acquired infections. Clinical cure was obtained in all infections with adequate dosage, but in induced *P. falciparum* malaria radical cure was obtained. Clinical cure was also brought about in a small group of induced *P. vivax* infections after a single dose of 100 mg. At the time of writing the report, cases of *P. vivax* malaria treated with paludrine had not been followed up long enough to check the possibility of radical cure. The authors suggest, however, that "the weekly administration of 1-2 tablets (0.1 to 0.2 g.) indefinitely would prevent relapses until cure was attained." As pointed out above, such a dosage regime is now being investigated by the Liverpool workers.

⁶ Researches on Paludrine (M. 4838), A Progress Report. (From H.Q., A.M.P., Aust. Army Medical Research Unit (A.M.P.), Cairns, Queensland. Director: Brigadier N. Hamilton Fairley.) 1946.

Paludrine was found to have no direct action on the production of gametocytes of either *P. vivax* or *P. falciparum*. It was discovered, however, that gametocytes failed to mature in the mosquito if the patient's blood was ingested by the insect while he was on the drug. A week after cessation of the drug (by which time most of it would have been excreted from the body) the gametocytes in the patient's blood grew to maturity when ingested by mosquitoes. Gametocytes failed to develop in mosquitoes given a partial meal first on healthy volunteers taking the drug and then on a gametocyte-carrier not on the drug. Fairley and his co-workers therefore conclude that paludrine acts on the developing gametocyte after it has been ingested by the mosquito and not while it is in the human blood stream. Although it is not truly gametocidal, paludrine thus prevents mosquito infection during a therapeutic course and subsequently, until the blood level falls below the effective concentration. It is superior in this respect to both quinine and mepacrine. Only minor side-effects were observed by the Australian workers after doses of paludrine of 1,000 mg. in a day. They confirmed the earlier observation that there is a considerable difference between the effective therapeutic range and the toxic dose.

These recent reports on the activity of paludrine are highly encouraging. It is to be hoped that further work in the field can be carried out without delay so that the very promising Australian experiments on the suppressive and prophylactic action of the drug can be expanded and confirmed.

CALCIUM AND PHOSPHORUS METABOLISM IN FRACTURE

In studying the metabolism of calcium and phosphorus in fracture cases Cuthbertson¹ noted that there was a considerable divergence in the metabolism of these two elements. Calcium metabolism, determined by the intake and output during an early (second week) and late (fifth to ninth week) period, showed little departure from a normal balance—if anything there was a loss during the latter period—but there was a definite and early loss of phosphorus from the body. In a series of papers Cuthbertson^{2,3,4} has described the marked catabolic loss of nitrogen, sulphur, and phosphorus which takes place after practically all serious injuries, and with his colleagues he has investigated certain of the factors which influence it. Combined radiographic and biochemical studies on fracture cases supported Leriche and Policard's⁵ view that the genesis of new bone is conditioned by the absorption of pre-existing bone, and that this process of rarefaction, which is coincident with anabolism, probably begins immediately after the trauma. Where apposition is poor or there is other hindrance to healing, the bones may waste themselves on an impossible task.

To determine how far urinary lithiasis consequent on prolonged immobilization is due to the loss of lime salts

by way of the urine, Howard, Parson, and Bigham⁶ have recently investigated the calcium and phosphorus balance in a group of 17 male patients, immobilized in bed for the healing of a fracture or of an osteotomy and with complete leg and partial body casts; 4 patients were studied before and after femoral osteotomy for slipped epiphyses. In their fracture cases the maximum excretion of calcium was reached approximately one month after the injury and was maintained for 30 to 60 days, or until mobilization of the patient. After osteotomy the urinary excretion of calcium followed a similar pattern, although maximal excretion of calcium was reached much sooner. The urinary excretion of phosphorus reached its peak at the height of the protein catabolism, falling to a low level at the end of the period of nitrogen wastage. These changes in nitrogen and phosphorus excretion were similar to those previously noted by Cuthbertson. In the American series the maximal excretion of calcium was reached in all cases at a time when the protein catabolism reaction had waned. This reciprocal relation between the peak intensity of urinary excretion of calcium and of protein catabolism is corroborated by similar findings in osteotomy cases in which the period of increased protein catabolism is shorter. No routine x-ray examinations were made, but only 2 of the 17 patients had any symptoms or signs suggestive of nephrolithiasis. These were the cases of femoral osteotomy. One patient developed haematuria and calcium casts during the administration of calcium lactate; no pain was experienced, and the abnormal elements disappeared with cessation of its administration. The other patient had frank renal colic with red cells in the urine. These manifestations occurred in both cases during the plateau period of calcium excretion—that is, approximately eight weeks after operation. Howard and Bigham, in some work as yet unpublished, found that patients with induced malarial chills, watched for twenty to thirty days at rest in bed, showed no increased urinary excretion of calcium compared with their pre-febrile control. They therefore attribute the increased calcium excretion to rarefaction of the immobilized skeletal area, the speed of rarefaction being conditioned by the difference in the rate of resorption and of new bone formation.

Cuthbertson⁷ showed in 1929 that a definite but small rise in the output of nitrogen, sulphur, and phosphorus, and to a lesser degree of calcium, follows the immobilization by splinting of a sound limb in normal subjects. Dietrick⁸ has also demonstrated a slow progressive rise in urinary calcium in two healthy young men immobilized in casts below the waist. In one of his two cases the extent of the rise was of the order of the average excretion in Howard's patients. Some years ago Pearse and Morton⁹ made the interesting discovery that hyperaemia, induced by venous obstruction, accelerated the healing of fractures in dogs. In every instance there were earlier callus formation, earlier calcification of the callus, and earlier union on the side in which the vein was ligated. The mechanism whereby the venous obstruction effected this beneficial

result was not clear. Howard, Parson, and Bigham believe that the early hyperaemia of the inflammatory reaction about the fracture site may be a major reason why the urinary excretion of calcium is at first normal and only gradually rises. The local inflammatory reaction following osteotomy is probably considerably less than that after fracture and wanes much more rapidly, as is perhaps reflected in the shorter and less vigorous catabolism. Howard¹⁰ has suggested that the protein catabolism is closely related to, if not initiated by, absorption of products of tissue necrosis. Cuthbertson and Munro¹¹ observed that in rats, at least, the catabolism of protein is bound up with the body reserves, for if the latter have been depleted by subsistence on a protein-free diet there is virtually no further loss of nitrogen after fracture. It is probable that the loss of calcium is bound up with disuse atrophy, for the body does permit a reduction in that which is not in use.

WHAT IS NORMAL TEMPERATURE?

It is commonly stated in textbooks that the normal range of oral temperature in the healthy human body is from 97° to 99° F. (36.1° to 37.2° C.), and that the rectal temperature is 0.5°–1.0° F. (0.28°–0.55° C.) higher. This corresponds approximately to the results obtained by many investigators (e.g., Gessler¹²) and may be accepted as a working guide in temperate climates. A very cursory dip into the literature, however, is sufficient to reveal that the extremes of normality may be wider than this, though the great majority of healthy individuals have body temperatures within the limits given above: thus, Ivy¹³ found that the oral temperatures of 276 healthy students sitting in class after breakfast varied from 96.5° to 99.3° F. (35.8° to 37.4° C.); Du Bois¹⁴ gave the range for oral temperature as 97° to 100.2° F. (36.1°–37.9° C.); while Renbourn and Bonsall, in a paper published to-day in this *Journal*, show that during the summer months in North India both British and Indian troops may have oral temperatures up to 100.6° F. (38.1° C.) and rectal temperatures up to 101° F. (38.3° C.). The relation between oral and rectal temperatures, too, is apparently not nearly as constant as is commonly taught: Carmichael and Linder,¹⁵ in parallel estimations on 24 normal subjects, found that the average difference in individuals ranged from 1.79° F. (0.99° C.) to 0.42° F. (0.23° C.), while in one case the rectal temperature was 3.5° F. (1.9° C.) higher, and in another was 1.7° F. (0.94° C.) lower than the oral reading; they quote the results of several similar investigations by other observers, who found variations ranging from 0° to 2.0° F. (1.11° C.). Renbourn and Bonsall have also observed that the rectal temperature may very occasionally be higher than the rectal.

The question is by no means merely one of academic physiology. Physicians are not infrequently confronted with a patient complaining of indeterminate symptoms and presenting no abnormality on examination except a "persistent low-grade fever": sometimes a definite cause can be found, such as pulmonary tuberculosis, a chronic urinary infection, or, in the Tropics, chronic malaria; in many cases, however, routine investigation proves entirely

negative and the physician is faced with the question whether to spend further time and money on even more exhaustive bacteriological and radiological investigations, or, accepting the slight "fever" as within the normal limits for the temperature of that particular patient, to pursue a policy of masterly inactivity and vigorous reassurance. The subject has been discussed by Alvarez¹⁶ in a recent editorial. He points out that these patients are frequently tense, nervous women, and that such people tend to have body temperatures higher than those of ordinary quiet persons: frank psychological disturbances, too, may be associated with persistent or intermittent "fever," and Alvarez mentions two cases of persistent temperatures of 100°–101° F. (37.7°–38.3° C.) in women who had contracted unhappy marriages. Other cases of "psychogenic pyrexia" are quoted by Wolf and Wolff,¹⁷ who also add a remarkable case of their own. According to Alvarez, there is a tendency in the United States to make a diagnosis of brucellosis in such patients, but in his opinion this is incorrect in most of the cases.

Any patient whose oral temperature rises every day to between 99° and 100° F. (37.2° and 37.7° C.) is clearly entitled to a search for all the usual varieties of chronic infection. If this proves negative, however, there seems little doubt that reassurance and encouragement to resume a normal life represent a wiser policy than prolongation of the period of invalidism by over-enthusiastic bacteriological investigation, and that this applies particularly in the case of "nervous" patients and in tropical or subtropical areas. The thermometer, like the sphygmomanometer, should assist but never replace clinical common sense.

ORGANIZATION OF CANCER TREATMENT

The 16th annual report of the National Radium Trust and Radium Commission¹⁸ is of particular interest because it not only records the activities of this organization during 1944–5, but also contains observations on the annual reports of the war years which were not allowed to be published for security and other reasons. In view of the Cancer Act passed in 1939 it became necessary to amend the original Charter, and to enlarge the membership of the Commission from ten members to seventeen, the additional members being representatives of local authorities; and radio-active agents other than radium and x-ray apparatus are now under the direction of the Commission. Though the carrying out of the 1939 Cancer Act has been postponed from year to year during the war, nevertheless the local authorities have been trying, where possible, to organize cancer services, and the Radium Commission has been able to give a great deal of help in drawing up such schemes. In 1942 it published a pamphlet on the organization of cancer treatment in which it expressed the view that the treatment of this disease could be carried out successfully only if surgery and radiotherapy were in intimate association. Experience has led the Commission to advise that radiotherapy should not be carried out except by people who have a thorough and up-to-date knowledge of the physical principles and practice involved. The necessity of physicists being an integral part of the staff is emphasized. It further points out that the number of centres in the country having facilities for radiotherapy should be strictly limited, that such centres should be fully equipped with modern apparatus operated by a team of experienced radiotherapists, and should serve a population if possible of not less than two millions.

¹⁸ Cmd. 6817. H.M. Stationery Office. (1s. 3d.)

The report refers to cancer records. The 1939 Act states that the keeping of such records should count and be paid for as part of the cancer service. The importance of records cannot be overstated. Cancer treatment is still in the stage of research, and detailed records are therefore essential, not only for the individual but also for improving methods of treatment. The Commission has drawn up a system of records which involves the registration and follow-up of every patient suffering from, or suspected to be suffering from, cancer. In addition to the national statistical records it is hoped that every centre will keep much more detailed records from the point of view of research. The registration and analysis cards are now being collected by the National Radium Commission, but it is understood that the Ministry of Health will shortly set up a National Medical Statistical Bureau. It is too early to say how the forthcoming National Health Service Act will affect the organizations for the treatment of cancer, but it is unlikely that it will reverse the principles laid down by the Commission, which are based on sixteen years' experience.

WELFARE OF THE CHILD

Much has been done and is being done in this country, by legislation and by voluntary effort, to improve the chances in life of our children. Miss Rosalind Chambers and Miss Christine Cockburn have summarized, in their pamphlet entitled *The Nation's Children*,¹ the existing provision and its shortcomings. While the country is waiting for a comprehensive health service, antenatal care must, they say, be improved, the service of the infant welfare clinics amplified, and the war against children's diseases made more effective. The education in dietetics which rationing has brought to us all must be impressed on expectant and actual mothers by a campaign of education, and school-children must have good food and milk. Every family must have sufficient income to buy adequate food even in times of illness and unemployment. Women must be trained in child care and home management rather than sent to prison for neglect. Good and suitable homes must be found for families; the provisions of the new Education Act must be carried out with enthusiasm. The care of orphans and homeless children must be improved, especially by providing better-paid and better-trained staff for the institutions which house them. The same need shows itself throughout all the services for children: the need for conditions which will attract the right people. The present complexity and chaos of organization need simplifying, but not at the expense of the freedom of the many voluntary workers who now give such valuable service. The authors show keen insight into a very wide and varied complex of problems.

THE DISCOVERY OF INSULIN

This year is the 25th anniversary of the discovery of insulin, and the Diabetic Association is arranging silver jubilee celebrations to commemorate the event. Sir Frederick Banting was killed on active service, but his co-worker, Prof. C. H. Best, F.R.S., is coming over from Canada and will address a gathering at the Royal Institution, Albemarle Street, W., on Friday, July 5, at 4.30 p.m. He will be supported by Sir Henry Dale, late President of the Royal Society.

Attempts had been made before Banting's time to separate insulin from the other secretions of the pancreas, but none had been successful. Banting believed that he

could achieve the essential separation if he were given sufficient facilities for research. He found in Prof. J. J. R. McLeod, of Toronto University, a whole-hearted sympathizer. Unfortunately, the help that McLeod was able to give was limited, but Banting was supplied with a laboratory, and with animals to work upon. McLeod also turned over to Banting a young postgraduate researcher named Charles Best. The work was beset with difficulties. Often when a solution appeared in sight the final result was unsatisfactory. Funds ran low, and Banting and Best sold many of their personal possessions to keep their experiments going. Eventually success came, and in the summer of 1921 they discovered a method of extraction of insulin. The tests on animals were satisfactory, and then came the day when the extract was first used with a human being. The patient was a young diabetic dying in one of Toronto's hospitals. He regained his strength and continued to live a normal and healthy life. For their work Banting and Best were awarded the Nobel prize, and Banting was knighted. Of the partnership only Best remains. Prof. McLeod died in 1935, and Banting was killed in an aeroplane crash in 1941, while flying on a Government mission.

THE ROTUNDA BICENTENARY

As already announced, an international congress of obstetrics and gynaecology to celebrate the bicentenary of the Rotunda Hospital will be held in Dublin during the week beginning July 7, 1947. The actual bicentenary year of this famous institution was 1945, but the arrangements could not be made effective then owing to the war. The programme committee, fully representative of the Rotunda, the Coombe, and the National Maternity Hospitals, has drawn up a programme. To facilitate travel reservations and hotel accommodation the committee asks those proposing to attend the congress to register at an early date with the honorary secretary, Mr. G. F. Klingner, F.C.A., Rotunda Hospital, Dublin, or with the local offices of Thomas Cook and Son, Ltd. The completed programme, with details of the scientific papers and of the social functions and entertainments, will be circulated towards the end of this year and a copy sent to all who register. The subject for the opening session on July 7 is the history of midwifery, followed by a discussion on puerperal sepsis; on July 8 eclampsia is the subject. The programme for July 9 has yet to be arranged. On July 10 sterility is the subject; on July 11 foetal and neonatal mortality; and on July 12 shock in obstetrics. At these sessions leading obstetricians and gynaecologists from various countries will take the chair or speak in the discussions.

Dr. P. M. D'Arcy Hart will deliver the Mitchell Lecture before the Royal College of Physicians of London on Tuesday, July 9, on "The Search for Chemotherapeutic Agents in Human Tuberculosis during the Past 100 Years." Prof. C. A. Lovatt Evans, F.R.S., will deliver the Bertram Louis Abrahams Lecture on Tuesday, July 16, on "The Outlook of Physiology To-day." Both lectures will be given at the College, Pall Mall East, at 5 p.m.

We regret to announce the death of the eminent neurologist, Dr. James Taylor, consulting physician to the National Hospital, Queen Square.

Sir Alfred Webb-Johnson, Bt., President of the Royal College of Surgeons of England, has been appointed Hospitaller of the Order of St. John.

THE PROBLEM OF MEDICAL EDUCATIONAL FILMS

BY

Prof. NIELS DUNGAL*

The great value of educational films has been definitely proved in training schools during the war now ended. Probably no other branch of the military forces used films so extensively for educational purposes as did the engineering schools, where air-men, electricians, and all kinds of technicians were trained by that means for several hours daily. The Americans stated that his method cut down the training time to 50% and even 25% of what it would otherwise have been. As the fight for victory became mainly a fight for time, it is easily understood how valuable this method of teaching was, quite apart from the considerable reduction in maintenance costs for hundreds and thousands of troops.

Difficulties in Ordering Medical Films

Although a great number of medical films are now available, teachers who try to obtain them will encounter certain difficulties. They will find that they have to write to a great number of firms, universities, and private persons who are in possession of various educational films. They will get in reply lists of film titles, usually with the running time indicated, but as a rule no adequate judgment can be formed as to whether a likely-looking film is really suitable for the purpose desired. The films can be rented or bought, but to establish a film library means a considerable expenditure, as copies are rather costly. So if, as is usually the case, there is no possible means of evaluating the films in question, the prospective buyer decides in favour of a limited number. Our experience is that, under present conditions, we have to be content if as much as 25% of the films we order come up to our expectations. Surely the finance committees of universities cannot be blamed for discouraging the acquisition of films under such conditions.

Several firms in the medical trade, and particularly manufacturers of drugs, have produced films—many of them of the highest value—for the purposes of medical instruction, which they distribute without charge. Most of these contain an element of propaganda, which, however well concealed, is not in accord with the neutral standpoint of university teaching. An educational film should be made for the sole purpose of instruction, without the least bias towards any commercial interests.

Some of the best films have been made by public authorities. The picture on "Scabies" produced under the auspices of the British Ministry of Health might be taken as an example of the highest order of medical educational films. It contained a full statement of facts, well presented by an able specialist, illustrating pathology, clinical symptoms, treatment, and prevention better than could be done in a lecture without a film. The difficult method of finding the parasites, and the course of their development, were shown in rapid succession, not possible in any other way. From such a picture the student will profit more than by listening to the most gifted instructor or by reading the best textbooks. And this kind of instruction has the advantage of being presented in a way which appeals strongly to young people.

Special Advantages of Film Instruction

In a small university, where patients are not numerous enough to supply the demand for all kinds of cases, the film has the evident advantage of presenting readily available material for demonstration. Even the biggest clinics with the most varied material are not infrequently handicapped by the lack of what is called a "typical case"; and no university is usually able to present the rarer cases at will. Yet a rare case should not be considered an unimportant one. In many countries congenital syphilis is now a great rarity. It is, however, one of the most important diseases to know, as neglect of such a case is apt to cause inestimable misery not only to the patient but also to others.

Some diseases can be demonstrated better in a film than in any other way when patients are not at hand. The movement in various disturbances of the central nervous system can be faithfully recorded: tetanus, chorea, paralysis agitans, the various forms of syphilis of the central nervous system, and a great many other diseases can be very strikingly demonstrated in an ordinary motion picture film. The stuttering speech in many nervous disorders is easily recorded, and as some of these diseases are among the rarest and are yet of the greatest importance, the value of recording them on films for scientific purposes is easily realized.

Sound-recording will be found invaluable in the various disorders of the heart—not only the common forms of endocarditis and syphilitic affections but also the rarer congenital lesions, such as persistent ductus arteriosus and septum defect, both of which are associated with an abnormal sound effect that is not easily forgotten by those who have once heard it.

Pathology and public health are equally well served by faithfully recorded developments of various parasites and of diagnostic and preventive methods. Control of malaria cannot be better taught to an audience than by good films made for the purpose. The same applies to plague, yellow fever, kala-azar, hydatid disease, and other infections of bacterial and parasitic origin.

Most doctors know too little about the science of genetics and heredity. With all the various duties which medical study demands of a man, it is hardly to be expected that the average medical student can gain sufficient insight into the complicated science of genetics. The fundamental facts of this science could in no other way be so easily demonstrated as in an animated film, in which the chromosomes could be mapped and inspired with life, and in which the artist, under expert guidance, could depict the processes which determine the quality of a new individual.

Need for Organization

In the United States the American Film Centre has a branch for medical educational films, which collects and evaluates medical films from various sources. Dr. Adolf Nichtenhauser has been very active in this branch of the A.F.C., but the funds appropriated to this work have been so insignificant that expansion beyond the walls of a small office has not been possible. What is needed is organization on a grand scale for all English-speaking peoples. If one centre were set up for the U.S.A. and another for the British Empire, co-operation between the two would ensure that both did not carry out the same task simultaneously, but rather divided the work between them.

There are at present over 150 universities in the United States and the British Empire. It may safely be assumed that a great number of foreign universities would wish to acquire good medical films if they were available from reliable sources. The producers should therefore have a market for at least 100 and probably nearly 200 copies of each film. When we consider that an ordinary commercial film in America has 300 copies—sufficient to cover the world market—100 to 200 copies of a scientific film should be a sufficient basis for the economic security of the enterprise. As most universities would probably desire to have a film library of their own, the copies would mostly be sold, which would be of advantage to the producers, to whom ordinary commercial films are returned. Scientific films would not need the expensive salesmanship which commercial films require, and scientists would demand only a fraction of the salaries that at present are paid in the motion picture industry.

Even if the use of motion pictures should not in the end shorten the training time of medical students, as more knowledge is constantly being added, they will make a welcome variation to the medical curriculum and contribute in no small degree to the art of teaching medical science.

Nearly 3,000 male nurses will benefit as the result of new Rushcliffe Committee salary scale recommendations. In a circular to employing authorities the Minister of Health says he welcomes the recommendations and suggests their adoption. Half the extra cost will be borne by the Exchequer. The nurses to benefit are those employed in hospitals and public assistance institutions, and in sanatoria, tuberculosis hospitals or hospitals mainly concerned with the treatment of this disease, and tuberculosis wards.

* From the Department of Pathology, University of Iceland, Reykjavik.

The annual report of the National Council of Social Service for 1944-5 has been issued from 26, Bedford Square, W.C.1. The report begins by tracing the history of the Council since its foundation in 1919: "The dominant idea underlying its work has been the promotion of an effective partnership between the machinery of Government and the voluntary activities of the community." It shows how the responsibilities of the voluntary societies have increased step by step with the increasing assumption by the State of responsibility for the social needs of its citizens.

Outstanding features are recorded in the development of voluntary social service in the countryside. Before the war over 600 village halls were built with assistance from funds provided by the Carnegie United Kingdom Trust, and by the Treasury, through the Development Commission. Since the end of the war there has been a great revival of interest in village halls; the Carnegie Trust has set aside a further sum of £100,000 over the next five years, and the Development Commission has resumed its aid. The scheme has been correlated with the development of community centres, and over a thousand new village hall schemes are already in train.

The campaign for reviving the parish council, the smallest unit of local government in the country, has met with much success. The rural community councils have continued to provide leadership to their counties over a wide range of activities, including education, music and drama, rural industries, and after-care and health services. In the urban areas the report notes a new interest in the work of local councils of social service. The citizens' advice bureaux will go on in peacetime, because the need for their services is as great now as it ever was in time of war, and a national conference addressed by the Minister of Health in 1945 confirmed this view. Another development noted in the report is the tremendous enthusiasm all over the country for community centres. Reference is also made to the Council's library and information services, and to the fruits of its research work.

It is a sign of the Council's vigorous impact on contemporary social life that the interests covered by its consultative work range from old people's welfare to youth service, the Adoption Acts, playing fields, and training for social work.

PENICILLIN IN THE B.P.

Penicillin and seven preparations of it are the subjects of new monographs in the *British Pharmacopoeia*, 1932, notice of which has been given in the London, Edinburgh, Belfast, and Dublin *Gazettes* by the British Pharmacopoeia Commission. Penicillin itself is defined as the anti-infective acid produced when *Penicillium notatum* or related organisms are grown under appropriate conditions on or in a suitable culture medium, converted into the sodium or calcium salt. When pure, penicillin (sodium salt) is a white powder which may occur as granules or scales; it contains 1,666 units per mg. When has not been completely purified (sodium or calcium salt) it is a pale yellow to light brown amorphous hygroscopic powder, containing not less than 300 units per mg. It is very soluble in water and insoluble in fixed oils and in liquid paraffin. It is dispensed in sealed containers, the materials of which do not affect the potency of penicillin, and must be stored at as low a temperature as possible, not exceeding 10° C. The label on the container states whether it is sodium or calcium penicillin, the total number of units in the container, and the minimum number of units per mg. of the penicillin.

The preparations are cream of penicillin (cremor penicillini), sterilized cream of penicillin (cremor penicillini sterilisatus), injection of penicillin (injectio penicillini), oily injection of penicillin (injectio penicillini oleosa), penicillin ointment for the eye (oculentum penicillini), lozenge of penicillin (trochiscus penicillini), and ointment of penicillin (unguentum penicillini).

The Commission's notice contains an appendix on the biological assay of penicillin and a warning that, in any part of the British Empire where penicillin is controlled by law, care must be taken to comply with the provisions of such a law.

At the request of the Minister of Health his Central Housing Advisory Committee has set up a subcommittee "to advise on matters relating to domestic equipment, fittings, and components for houses from the standpoint of domestic convenience," and one of the members is Dr. J. Greenwood Wilson, M.O.H. for Cardiff.

MEDICAL USES OF PENICILLIN

"The medical uses of penicillin" was the subject discussed at a meeting of the Section of Medicine of the Royal Society of Medicine on May 28, and it attracted a very large audience; but apart from the two openers, Sir Alexander Fleming and Prof. R. V. Christie, no one came forward to sustain the discussion, and after a few questions had been asked and answered the meeting ended. Dr. T. IZOD BENNETT was in the chair.

Sir ALEXANDER FLEMING said that there were two chief ways of giving penicillin—namely, into the blood stream and by local application. Both had their uses, and, of course, penicillin when injected into the blood stream did not get everywhere in high concentration, as, for example, into a large abscess or empyema. The amount given should be sufficient to destroy the infecting organism. Penicillin was the only chemotherapeutic agent which was quite non-poisonous; and therefore no trouble was to be apprehended from overdosage. Much greater danger lay in underdosage. Bacteria, like other living creatures, had a power of adaptation, and if a non-lethal dose was given they quickly recovered and became resistant to penicillin.

The usual method of administration had been three-hourly injections day and night, but this was being given up in favour of one or two large doses a day. If made up in a simple watery solution, penicillin to the amount of 100,000 units was out of the circulating blood in about six hours, but by making up in oil-wax mixtures the time during which it was in the blood could be prolonged. With the greater availability of penicillin it was now justifiable—as it was not a year ago—to increase the amount, at the same time lengthening the interval. Thus the ordinary treatment of 15,000 units every three hours meant 120,000 units a day, but this might be raised to 100,000 units every six hours which meant 400,000 units, or 300,000 units every eight hours which meant 900,000 units, or even 500,000 units every twelve hours which meant 1,000,000 units a day.

At the moment the administration of penicillin by inhalation was being widely practised. If 100,000 units were inhaled morning and evening penicillin would be maintained in the blood practically all the time. If the sputum were examined, high concentrations of penicillin would be found; 2,000 units per ml. had been present in the sputum twelve hours after inhalation. This was a method which might well become more popular in the treatment of chronic bronchitis. Organisms like the pneumococcus and streptococcus were penicillin-sensitive and disappeared within two days; even Pfeiffer's bacillus disappeared, but the place of these was likely to be taken by Friedländer's bacillus and other organisms, and in some cases the result was just as bad as before treatment. Penicillin lozenges were useful, but in certain patients produced an unpleasant stomatitis. Here again, while the streptococci disappeared from the mouth, their place was taken by penicillin-insensitive organisms, which might be worse for some patients than the streptococci.

Combination with Other Drugs

A further question, Sir Alexander Fleming continued, was whether penicillin should be given by itself or in combination with other drugs. Two classes of drug immediately came to mind in this connexion—namely, the sulphonamides and the arsenicals. Penicillin powder was generally made with sulphathiazole, and the two were perfectly compatible. If an organism became "fast" to the sulphonamide it was scarcely likely to be "fast" to penicillin, and vice versa. Many laboratory experiments had been made in which an organism had been exposed to mixtures of penicillin and sulphathiazole or other of the sulphonamides, each ingredient being insufficient by itself, but the combination of the two had destroyed the organism. In the treatment of syphilis many workers had suggested a synergism between penicillin and the arsenical preparations. This was a point difficult to prove, but it might be that the future treatment of syphilis would be by penicillin with arsenic or with some other agent which affected the spirochaete. The

new streptomycin affected most of the organisms that penicillin affected, as well as a good many others, but it appeared to act in a different way, and a penicillin-streptomycin combination might be effective.

The question of length of treatment was one difficult to decide. Treatment must be continued long enough to eradicate the infection, and it was not easy to know when to stop. With a staphylococcal infection it might be necessary to go on for a week or more, and with some infections for a much longer period. With regard to penicillin given by mouth, if enough were given it was generally possible to get an effective action in the blood. But the amount absorbed varied greatly from patient to patient, and this was not entirely due to gastric acidity. One was not quite sure whether the patient was really absorbing the drug, and this made the method less sure than injection.

In conclusion Sir Alexander Fleming said that penicillin had given the physician a chance of effectively treating bacterial endocarditis and allowed the surgeon to perform operations which he would not have dared to do for fear of sepsis. But penicillin was not the end. Other chemicals, synthetic or natural, would be brought forward and would extend the scope of treatment. It would be important to use them, as it was now important to use penicillin, with intelligence and without abuse.

Penicillin for Bacterial Endocarditis

Prof. R. V. CHRISTIE spoke on the treatment of subacute bacterial endocarditis with penicillin, and described the results obtained in the 14 centres appointed by the Medical Research Council for the investigation of this disease. A review of the investigation was published in March (*Journal*, March 16, p. 381), and now it was possible to include a further two-months period of follow-up, and to add particulars of 58 new patients, bringing the total in the series to over 200.

The first experiment which was planned about a year ago was designed to show the relative importance of duration of treatment on the one hand and the total amount of penicillin on the other. The first 48 patients all received 5,000,000 units of penicillin, but the duration was varied. Twenty patients received 1,000,000 units a day for 5 days, and all these died or relapsed. Twelve received 500,000 units a day for 10 days, and of these 3 (25%) were apparently cured. Sixteen patients received 250,000 units a day for 20 days, and 8 of these (50%) were apparently cured. It was clear from this experiment that the duration of treatment was of greater importance than the total amount of penicillin given. Accordingly in the next group of 102 patients the duration of treatment was established as 28 days, but the daily dose was varied: 16 patients received 100,000 units a day, and of these only 6 (37%) were apparently cured; 48 received 250,000 units a day, and 21 of these (44%) were apparently cured; 38 received 500,000 units a day, and 27 of these (71%) were apparently cured.

Incidence of Relapses

It should not be forgotten that no matter how effective penicillin might prove to be in this disease, there would still be a certain proportion of patients—about one-third or one-fourth—who were bound to die of heart failure, major emboli, uraemia, and the like, and these deaths had little or no bearing on the efficacy of penicillin. It was the incidence of relapses which counted. Among the 38 cases just mentioned there were 9 relapses (27%). Of the patients who died, the septicaemia in 4 cases was uncontrolled up to the time of death; 2 of these died during treatment, one 14 days and the other 26 days after the start, and the other 2 died soon after treatment was completed. But even if these 4 fatal cases, 3 of which were infected with extremely resistant organisms, were reckoned as relapses, the results obtained by this system of dosage spread over 28 days were superior to any so far published in this country or in America, and this was the system which should be recommended in the treatment of this disease.

There remained, however, the cases in which there had been relapse after inadequate treatment and which presented a special and difficult problem. In 30 such patients, on further treatment, 7 died, 14 relapsed, and 9 were apparently cured. With the statistical help of Dr. Bradford Hill he had worked out the expected numbers in each of these three categories on

the assumption that the cases had not received previous treatment; the number of deaths was approximately the same, but the expected number of relapses was 3 as against the actual number of 14, and the expected number of cures was 18 as against an actual 9. It was quite clear that relapse after an inadequate course of penicillin therapy was prejudicial to later success. It might mean that these patients had acquired resistance to penicillin or that they belonged to a special group of naturally resistant cases, but whatever the reason in these relapsed cases 500,000 units a day for 28 days was insufficient. Just how much should be given was not as yet clear. It had been their custom to give 500,000 units a day for eight weeks, with some measure of success.

The relation of the sensitivity of the infecting organism to the results of treatment was also extremely interesting. Further experience had confirmed the published results and conclusions that the resistance of the infecting organism appeared to be of little or no practical importance within a wide range. In these resistant cases—which were very rare—again 500,000 units a day for 28 days was insufficient. It was probable that a higher daily dose should be given—1 or 2 million units.

Comparison of Statistics

How did these results compare with those published in the United States? Comparison was difficult because most of the published results had been on a selected group of patients—selected on the basis either of sensitivity of the organism or of the physical fitness of the patient. For example, Bloomfield published 16 cases with no relapses and no deaths, but although they were said to be consecutive patients they were highly selected, only those patients being included whose infecting organism was very sensitive to penicillin. One thing might be concluded from the British statistics, that they illustrated one of the advantages of poverty. It was the scarcity of penicillin which led to the institution of these 14 research centres working to a co-ordinated plan in the treatment of a rare but extremely fatal disease.

Prof. Christie concluded with a few remarks on the significance of certain clinical features of this disease as they bore upon prognosis. An analysis of the first 147 patients treated showed that 128 had rheumatic heart disease, and of these 40% died; and 16 had congenital heart disease, and of these 25% died. He thought there was a suggestion from these figures that the outlook for congenital heart disease was, on the whole, slightly better than the outlook for rheumatic heart disease. An analysis of the relation of heart failure to prognosis showed that of 106 patients with no heart failure 21% had died; of 25 with moderate heart failure 76% had died; and of 16 with severe heart failure when treatment started all but one had died (84%). He also showed the relation of the death rate to the patient's state of nutrition. Of the cases in which the nutrition was good 17% had died, and of those in which the patient was said to be emaciated 82% had died.

Finally, he had listed the causes of death. Heart failure alone was responsible for 29%; heart failure with other causes for 21%; uraemia for only 7%; major emboli for 11%; haemorrhage for 7%; and other causes for 25%. Though haematuria persisted for many months in successfully treated cases, no case of late uraemia had as yet been reported.

Questions

The PRESIDENT asked whether anyone had had experience of inhalation therapy. He had seen only a few cases, but he had been deeply impressed. Sir WELDON DALRYMPLE-CHAMPEYNS asked whether Sir Alexander Fleming had satisfied himself that there was available in this country a satisfactory apparatus for giving penicillin by inhalation, in particular an apparatus for giving it, not with oxygen, which was a little cumbersome at times, but with filtered air. Dr. GEOFFREY EVANS asked whether there would be different types of penicillin on the market, and whether they could be advised as to what type of penicillin should be used. Was one type better than another for the treatment of syphilitic meningitis, for example? What was the best method of mitigating the pain which some people experienced when penicillin was given intramuscularly?

Sir ALEXANDER FLEMING said that he did not know whether there was a specially good apparatus for inhalation, but with

the simple apparatus in common use quite a large amount of penicillin could be introduced into the blood. As for the different types of penicillin, this same mould under different circumstances would make at least four different types. These were called (1), (2), (3), and (4), but in America (f), (g), (x), and (k), and from recent reports (k) was not very good for syphilis. Nearly all the work here had been done with penicillin (2).

Prof. CHRISTIE, in reply to questions addressed to him, said that the criteria he used for assessing apparent cure were: negative blood culture, normal temperature after penicillin was stopped, and general fitness of the patient. The only sequelae observed were, first of all, the persistence of red cells in the urine, which might go on for many months, and, again for several months, a somewhat elevated B.S.R., although this usually fell quite rapidly. Asked about cases of known heart disease in which tonsillectomy or dental extraction was necessary, he said that he recommended a prophylactic course of penicillin, starting possibly twenty-four hours before the operation and continuing for about three days. He did not think it could be said dogmatically what dosage should be given, but 500,000 units a day was generally assumed. As for the relative convenience of intramuscular drip and intramuscular injections, about half the patients preferred the one and half the other. There was no evidence that the results of treatment with these two methods of administration were different.

OBSTETRICAL CASES

At the May meeting of the North of England Obstetrical and Gynaecological Society held at Newcastle-upon-Tyne Mr. S. A. WAY analysed a series of 500 cases of the lower-segment Caesarean section operation, personally performed by him, and compared it with the results of a smaller series communicated to the same society by Mr. Harvey Evers in 1934. Of this series the large figure of 320 represented disproportion between the head and the brim of the pelvis, and was the reason for the failure of a delivery through the natural passage, and in 74 cases the indication for the operation was the presence of a low-lying placenta. The maternal death rate for the whole series was 3.4%, which on analysis was found to be highest in the "failed forceps" group with a figure of 4.3%, and for placenta praevia one of 2.7%. This maternal mortality was lower than in the series of the year 1934, and he attributed this decrease to the treatment of septic cases with the sulphonamide drugs. Mr. F. J. BURKE reported a case in which a pregnancy resulted after tubal reimplantation performed for complete occlusion of the lumen of each tube near its insertion into the uterine wall, and Dr. G. P. MILNE and Mr. T. J. ROBINSON described interesting cases of developmental abnormalities complicating the picture of pregnancy and labour. Mr. LINTON SNAITH described his investigation into the skin lesions of cases of toxæmia of pregnancy to a placental site, and Mr. HARVEY EVERS a case of malignant disease of the vulva in a girl of 17 years. All these communications were discussed by the members present.

Contributors to the *Journal of Endocrinology* have recently taken the initiative in the formation of a Society for Endocrinology, the object of which is to promote the advance of endocrinology by observational, experimental, and clinical studies. The society was founded at an inaugural meeting held at Guy's Hospital on April 26, when the following elections were made: hon. secretary, Dr. S. J. Folley; hon. treasurer, Dr. C. W. Emmens; hon. editor of the Society's *Proceedings*, Prof. S. Zuckerman; members of committee, Dr. P. M. F. Bishop, Dr. A. S. Parkes, Mr. P. C. Williams, Prof. F. G. Young. In addition to ordinary meetings at which original scientific communications will be presented, the society hopes to organize from time to time symposia on selected topics in the field of endocrinology. The address of the hon. secretary is: c/o the National Institute for Research in Dairying, Shinfield, nr. Reading.

A meeting of the Medical Society of the L.C.C. Service was held at the County Hall on May 8. Papers were read by Mr. R. V. LEWIS-LLOYD on fractures of the hand, Mr. J. C. GILLIES on infections of the hand, and Mr. J. GABE on injuries to tendons, etc. The three speakers stressed the dangers of paying too little attention to the treatment of minor injuries and gave their views of the ideals to be aimed at in achieving successful treatment.

Correspondence

Hospital Treatment by Doctors outside the Service

SIR,—Considerations of space obviously lead to great condensation of your report on the proceedings of the Standing Committee on the Health Service Bill. Nevertheless, having read those proceedings in full, I feel that Mr. Bevan's remarks on May 21 about the use of hospitals by doctors outside the scheme are of such fundamental importance that the attention of the profession should have been directed to them in no uncertain terms.

Mr. Bevan stated, quite correctly, that "there are instances all over the country where a person who is chronically ill goes into hospital because he or she cannot get treatment at home. It may be that they suffer from something which does not require specialist treatment, but treatment by a general practitioner. I want to make it clear that the general practitioner should give that kind of treatment in a general practitioner hospital." On which he was asked: "Is the general practitioner covered who may be outside the service altogether?" And he replied: "Now the hon. Member is not pushing the door open, but is pushing the house down. If he is asking that a general practitioner who is entirely outside the public service is to have available the hospitals of the public service, he is asking for more than the specialist gets."

The obvious and only possible inference from Mr. Bevan's remarks is that no doctor who stays outside the service will be able to make use of any hospital at all, for all hospitals are to be inside the service. Mr. Bevan emphasized it later by adding: "If a doctor or a specialist cares to stay outside the service, it will be a little hard for us to provide facilities. I do not want to have a principle inserted in my scheme whereby general practitioners and specialists can sabotage the service by remaining outside."

That gives the whole show away. All the talk of the freedom of doctors to remain outside is meaningless if they are to be deprived of hospital facilities. All the talk of free choice of doctor is meaningless; for how can a patient choose a doctor who will be unable to attend him for any but minor ills? This rule—that only doctors in the service can use the hospitals—is blatantly a method for forcing all doctors into the service whether they wish it or not, for only by being in the service will they be able properly to treat their patients.—I am, etc.,

Ashted, Surrey.

W. EDWARDS.

Health Service Bill

SIR,—Perhaps you will allow me to make some comments on the Second Reading of the Health Service Bill. My first criticism is the unseemly haste with which the Second Reading was conducted. I would draw attention to the levity with which the Government has treated both the public and the profession with regard to the arrangements for the Second Reading, at which the principles of a Bill are settled. The Leader of the House at first proposed to take the Second Reading four days after the publication of the Bill, leaving only the week-end (which many members use for visiting their constituencies) for study of its eighty closely printed pages. The final allocation of time was 2½ days. The same levity is apparent in the decision to take the Committee Stage, not on the floor of the House as is the rule with all important measures, but in a committee room "upstairs." By this arrangement the Committee Stage is left to 50 members, whereas on the floor of the House the full 640 members form the committee. Perhaps I may mention in passing that as an independent Member—a status which I have maintained for 22 years—I receive no support from Party Whips, with the result that I had difficulty in catching the Speaker's eye during the debate and find no place on Committee "C."

I propose to confine my comments to the measures contemplated for the consultants, for whom I am most qualified to speak. The position of consultants was left practically untouched in the White Paper published by the Coalition Government in 1944, and the position of consultants still remains more fluid than that of the general practitioners' section. Whole-

hearted co-operation of the consultants is, however, of prime importance to the Minister. His scheme for health services differs from the provisions of the N.H.I. Acts precisely in the promise of specialist and institutional treatment, which was excluded from those Acts, and this provision has obviously been one of the principal baits offered to the public in the new Bill. The Minister's personal reaction to this section does not augur well for his ultimate control of consultants. There are ominous hints already in the proceedings of Committee "C" that he is preparing to make his own selection of consultants and his conditions for their terms of service and remuneration.

I would instance in particular his reference to the power he would exercise, when he has obtained control of the hospitals, in admitting to hospitals only those consultants whom he wishes to favour, with the implication that without that admission it will be impossible to follow consultant practice. It is true that he declares his intention of consulting an expert body in his choice of consultants, but that consultation remains permissive, not obligatory, and as the "expert body" is to be for practical purposes appointed by himself, its impartial authority is undermined. May I, in a digression, point out how farcical such protection proves in practice. In 1920 the House appointed a "consultative committee to advise the President of the Board of Education." It included some of the most distinguished educationists of our generation, but it was so seldom consulted that its final demise in 1938 was unnoticed until my question (*Hansard*, Jan. 26, 1944) revealed these facts. That committee was appointed by Parliament, whereas the consultative committees named in the Health Bill are to be appointed exclusively by the Minister.

The nationalization of the hospitals, which again constitutes one of the principal differences between the White Paper of 1944 and the present Bill, has a vital importance for the consultant section, and in no respect more vitally than in the effect nationalization must have on the prosecution of research, which has been conducted almost exclusively by consultants at the voluntary hospitals. I pointed out in my speech, in a passage which you were good enough to reproduce, that the Bill devoted only nine lines to the subject of medical research, which, those lines indicated, would be "conducted" by the Minister from Whitehall. Research conducted by a State Department has little attraction for the research worker, as has been shown in a recent incident. When the "conduct" of research into the atomic bomb was entrusted to the Minister of Supply the immediate result was the refusal of almost all the scientists most actively engaged in such research to accept membership of the Minister's team of workers. The reaction of British consultants immediately upon publication of the Bill showed a similar revolt against the proposal for nationalization of the hospitals, which, it was at once seen, would destroy the whole atmosphere of research as at present conducted at the voluntary hospitals.—I am, etc.,

House of Commons.

E. GRAHAM-LITTLE.

Medicine and the State

SIR,—It is interesting to note the marked alteration in tone in the correspondence in your columns on this subject which has occurred lately, and which coincides with Mr. Bevan's assumption of power as "medical dictator." To-day, almost every letter reveals a rising tide of justifiable indignation at the methods employed and the indignities to the profession resulting therefrom. In the past there were many letters appraising the Bill, or certain elements in it, but these voices are growing fainter and fainter as the days pass. For it is now clear where we are being led, and all the trappings and trimmings and unessentials are falling away. We are just left with the cold, hard, naked fact that the "dictator" intends as his first step to wrest freedom from the medical profession and the public, so that he and his Government have power to do anything and everything they think fit in medicine.

This he realizes he must do, and indeed his ultimate intentions are only thinly veiled. He can either ingest the meal at one gulp, which he is rather scared of doing, or take it piece by piece, more insidiously, until he has achieved his ends. It all savours, rather sickeningly, of the old, hackneyed phrase, "I have no more territorial demands to make." It is commonplace to-day to hear such pronouncements as, "Whether you like it or not, you are going to have it" and "We shall go

through with this scheme, co-operation or no co-operation" and "The Minister refuses even to negotiate with the profession."

A most excellent letter from Dr. Alfred Cox exposing the dangers of dictatorship in medicine is sent to the *Times* for publication, but the editor regrets that he is unable to publish it. To my mind there is no other issue at stake worth consideration except the preservation of freedom in thought and action for the medical man and the patient, and this is being, or is going to be, denied to both. If we stand by and acquiesce we are sacrificing the one essential for the future of medicine. Is, then, the profession to consent to such tactics?—for its consent to working the Bill is indispensable to the Minister, even if he does not yet realize it. Or is the profession to stand and fight and grasp with both hands a heaven-sent opportunity to hammer a long nail into the coffin prepared for dictatorial methods, which we have striven and suffered six long years to eradicate, spilled much blood in the doing, and emerged to find that we have only been loaded with it ourselves?—I am, etc.,

London, W.1.

A. R. DINGLEY.

"Appointment with Fear"

SIR,—This is a reasonable title, I think, for the situation facing most practitioners. For what stake will a thoughtful, well-educated man gamble with one throw practically the whole of his capital and his total income? This includes, of course, not only his own bread and margarine but a home for his wife and education for his children. For that is the situation if he decides to "strike" or, put into other words, "fight the Government." If the stake is "buying and selling of practices" will the man who has no practice fight? Will the man who has a big debt on his practice fight? Will all those who can get their money now on a good market fight? If the stake is "no part-salary" will the man fight who has a salary or a part-salary now? Will all those who publicly say they will fight do so to the limit or quietly quit?

I consider that before any husband or father can seriously consider this particular gamble he should have knowledge of certain facts: (1) The total numbers of doctors (including those in Government or local government employ) available. (2) The number of doctors who promise to refuse service and strike (I think there should be 80%). (3) Certain knowledge that those agreeing to strike are doing so and continuing to do so. For this latter the only knowledge of "form and fitness" of our team was the last time out in 1912. Then many were non-starters, most of the others failed to finish the course, and those who did received severe penalties.

It is necessary on this occasion to have some outward visible sign of those maintaining the fight. I think that every "striking" doctor should agree to take a locumtenency at least 15 miles away from his practice. The executive committees or adjoining Divisions could arrange this general post, and a rehearsal could be held at any time. I am willing to add my name to the list.

Without a well-organized plan we doctors should not attempt a "strike," as we would certainly fail. We can only war the public that there are not the doctors, buildings, equipment or staff to implement the promises of the Government, and that, with the limitations on the independence of doctors, their future service to the public must be worse and not better than at present.—I am, etc.,

Heacham, Norfolk.

P. S. MARSHALL.

Compensation under the Bill

SIR,—Dr. Geoffrey Dudley (May 25, p. 811) draws attention to the case of the medical man who "would not wish" to enter the service. Almost similarly placed is the consultant who, on account of age limit, has been retired from a hospital appointment but still continues in practice, and offers his services to the State and they refuse it—as they almost certainly would on account of his age. Under such circumstances the Minister would also be confiscating the practice. While the letters which appear weekly in the *Journal* are no doubt an outflow of righteous indignation, one wonders whether they are a useless outflow. It may be assumed the Minister of Health does not read them. Is the B.M.A. doing anything to bring the ideas expressed in them to his notice?—I am, etc.,

Norwich.

ARTHUR GREENE.

Notification of Venereal Disease

SIR,—A recent discussion at the Royal Sanitary Institute again focused attention on the much-disputed topic of the notification of venereal disease. Col. Harrison summed up against the proposal, and we have therefore to conclude that officially it is not yet in the region of practical politics.

The one big argument for the proposal put forward was the need for sanctions, as a final resort, for persistent recalcitrance. The present Minister of Health was quoted to the effect that at the back of all fields of endeavour in social effort there must be compulsion. The speaker quoted the work of a public health department where statutory powers are in existence, but where most of the results are obtained by compromise and agreement. Actual cases in the courts are rare. In other words, compulsion is a weapon to flourish, but not to use except in the last resort. With this premise and argument I think most people would agree, but where to find the weapon in this vexed question of venereal disease is a difficulty.

Article 148 of the Public Health Act, subsection (a), reads as follows: "A person who, (a) knowing that he is suffering from a notifiable disease, exposes other persons to the risk of infection by his presence or conduct in any street, public place, place of entertainment or assembly, club, hotel, inn or shop" shall be liable to penalties. If for "notifiable" disease in this section "infectious" disease was substituted and infectious disease, by Order, made to include venereal disease, it appears to me to give us such a weapon. Actually if it were cut short to read as follows it would answer the purpose: "knowing that he is suffering from an infectious disease, exposes other persons to the risk of infection, shall be liable to specific penalties."

The two chief types who are mainly concerned in the spread of venereal disease are: (1) defaulters; (2) the irresponsible professional and amateur.

(1) I should be prepared to put up notices in all clinics to the effect: (a) that treatment is free and confidential; but (b) draw attention to and quote the suggested enactment about spreading the disease; (c) urge continuance of treatment till freedom from infection is certified by the doctor. In the case of letters sent to defaulters the enactment should again be quoted. With the drastic decrease in the time factor in modern treatment and with the help of social workers, armed in the last resort with this enactment, a vast improvement should ensue.

(2) The persons here concerned are mostly subnormal or abnormal mentally or psychologically. They belong to one of the antisocial groups, and it is a question whether in a well-ordered society such groups should be allowed the amount of liberty they now enjoy. As things are, however, they form a very formidable problem. There is so often the practical difficulty from a legal point of view of establishing identification in specific cases—strong suspicion but not legal certainty. Pinning down one of these cases is one of the most difficult problems a social worker can encounter. Even so, an enactment of the kind suggested could be a weapon. So often, in this type—where it is morally certain a particular person is at fault—evasion is practised. To serve a copy of this enactment may at least have the effect of frightening where persuasion had failed.

I am not sufficient of a legal expert to know whether this clause could be made law under present Orders in Council or whether an amending Act would be necessary, but there appears no great difficulty in making it law if thought advisable.—I am, etc.,

C. M. OCKWELL.

Dartford.

Pregnancy in a Uterus Bicornis

SIR,—There would appear to be some serious confusion of thought in the mind of your correspondent, Dr. D. W. Robinson (June 1, p. 836), writing on the subject of "Pregnancy in a Uterus Bicornis." Can it be possible to remove "the right horn" and yet leave the uterus "almost like a normal one . . . with both tubes and ovaries in the usual position"? I suggest that it is frankly impossible. The possibility of angular pregnancy should be considered, and there is the exceedingly rare condition of diverticulum of the uterus which may account for this strange phenomenon.

Would it be possible for your correspondent to let us have some more details, and, if possible, a sketch of what actually was seen at operation? The case is surely worthy of careful presentation.—I am, etc.,

Carlisle.

G. A. ARMSTRONG.

"Cord Round the Neck"

SIR,—My own experience leaves me quite convinced that many stillbirths are attributable to this cause, and I have no "grave obstetric doubt." Unfortunately, I have not had the opportunity of carrying out all the tests and experiments suggested by Dr. Reddington's (Jan. 19, p. 109) and subsequent letters, but the following may be of interest.

In order to test the tension required to arrest the flow through the umbilical vessels a cork of a Winchester was fitted with three small copper tubes, to which were attached three lengths of cycle-valve tubing. One of these was attached to another short length of copper tube, filed and tapered for insertion into the umbilical vein, and the other two were fitted to serum needles with their points ground off and butts removed. A glass tube as an air vent was carried to the bottom of the Winchester. On inverting and suspending this apparatus, as in transfusion, before attaching to an umbilical cord, water flowed freely from all three outlets. The copper "nozzle" was inserted into the umbilical vein and tied with silk and the two needles were inserted into the arteries and tied. Though three umbilical cords were tried a satisfactory flow of water was not obtained through the arteries, but the flow through the vein was free and continuous. A flexible tube was attached to the external end of the air vent so that air could be blown through to increase the air pressure within the Winchester. The cord was suspended on a wire which perforated the end between the insertion of the "nozzles" so that the suspension did not pull the vessels away and were not accidentally compressed. Direct tension on the cord of several pounds had little or no effect on the flow of water, but with one coil of cord round one's wrist held horizontally the flow of water through the umbilical vein, at a pressure of 80 mm. Hg, was completely arrested with a pull of 1 lb. 2 oz. (510 g.). With two coils round the wrist the flow was arrested with a weight of only 8 to 10 oz. (224 to 280 g.). It was found with the cord hanging loosely and water flowing freely with forced pressure from the Winchester that the flow was completely arrested by the action of a mercury sphygmomanometer at 80 mm.

It may be that the "live" cord with both arteries conveying blood under pressure might continue to supply oxygenated blood to the foetus against considerably greater pressure or tension on the umbilical vein than that required to arrest the flow of water in this simple experiment. It was my intention to repeat this experiment after having forced a flow through both arteries. The experiment was attempted from both ends of the cord—i.e., with the needles inserted into the umbilical end of the vessels and in the foetal end, the results appeared to be the same. I wished also to take the B.P. of the umbilical cord before pulsation ceased, immediately after birth, and to test the required tension on the cord wound round the wrist to stop pulsation. As I am not likely for many months to have the opportunity of doing this, I suggest it to others. From this it would appear that a child could very easily be asphyxiated by tension on the cord round the neck as the head is forced further from the placental site, and I believe this is what not infrequently takes place.

I remember one case, particularly, which occurred some years ago. I was satisfied at the time and I am still satisfied that the cause of death was asphyxiation due to tight coils of cord round the neck. The mother was a healthy young primipara with good pelvic measurements, but the head remained on the perineum without advancing for about two hours and with no obvious reason for the delay. I fidgeted to deliver with forceps, but fearing the accusation of impatience, and having taken to heart too deeply the preaching on "meddlesome midwifery," I allowed this woman to deliver herself of a stillborn infant with the attenuated cord stretched tightly round the neck. Perhaps this life could have been saved by early forceps delivery. As the frequency of cord round the neck is said to be one in four or one in five deliveries, one might expect an even greater mortality than actually occurs, and it is difficult to imagine that one can have attended a great number of confinements without having been confronted with this tragedy.

It would seem probable that repeated tension on the cord if the cord be looped round any part of the child's body, limbs, or neck during a prolonged second stage would cause foetal distress and eventually asphyxiation, and that asphyxiation would result from occlusion of the umbilical vessels, and this would probably occur in the case of cord round the neck before constriction of the cervical vessels could occur. In another case of my own I attributed death to asphyxiation due to tension on the cord, which was wound tightly twice round the body of

a child delivered by the breech. Except for this unexpected complication of the cord, delivery was easy, and I do not think that in this case the cord was compressed against the maternal pelvis.

In addition to the possibility of asphyxiation due to tension on the cord round the neck are to be added the possible difficulties and complications due to the artificially shortened cord, such as retroplacental haemorrhage as mentioned by Dr. I. G. Cameron (Feb. 23, p. 291). I have noticed several times when patients have had strong uterine contractions with only very slow progress but have complained of intense pain at each contraction, and often after forceps delivery, that there has been a very short cord or the cord artificially shortened by being wound round the neck. These patients are often thought to be making a great fuss over nothing. "She has good pains but won't use them" is often reported.

Other points which occur to me and perhaps have not been fully investigated are: What effect, if any, is there on the capillaries of the placenta if the cord is sufficiently constricted to occlude the umbilical vein for considerable periods without compressing the arteries? Can the strain on the foetal circulation due to constriction of the umbilical cord be an aetiological factor in congenital heart disease—e.g., patent foramen ovale or ductus arteriosus?—I am, etc.,

Huddersfield.

S. H. WADDY.

Congenital Hypertrophic Pyloric Stenosis

SIR,—I am grateful to Dr. Margaret Smyth (June 1, p. 851) for drawing attention to an error of omission in my paper on pyloric stenosis. As I had previously (*Lancet*, 1944, 2, 748) given a detailed account of my method of medical treatment, I included only a brief summary of it. I failed to point out that the initial feed-volume reduction is maintained for 24–48 hours, and subsequently there is a daily increase of 1/2 oz. (14 ml.) until the infant is taking its full caloric requirements. When this stage has been reached the vomiting does *not* return and the gain in weight is satisfactory.

Dr. Smyth gracefully admits that her experience in this field is limited, and had it not been so I am sure she would not have been under the impression that my care of each case was limited to ten days. Actually, every case treated medically was seen periodically for at least four months and until medication had been stopped and it was certain that the vomiting had not returned. I can assure Dr. Smyth that my "optimism" is not based on ignorance of what happens after the infant leaves hospital.

I read with interest Dr. Smyth's report of her own two cases, and I note that the second was given atropine methyl nitrate for only three weeks. She will observe that I continue medication for sixteen weeks. The reason for this is that the average duration of pyloric stenosis is about sixteen weeks, and if medication is stopped before the disease has run its natural course the vomiting is likely to return. I believe that, even at its late stage, if Dr. Smyth restarts her second son on a full course of atropine methyl nitrate his vomiting will cease.—I am, etc.,

Tunbridge Wells

N. M. JACOBY.

Psychology in the Child's Education

SIR,—An Educational, Scientific, and Cultural Organization has been established under the auspices of U.N.O. This offspring of the parent body is likely to exceed it in importance and achievement if it can direct and control educational curricula throughout the world. The place to plan world security is in the class-room. We know from unfortunate experience how successfully children can be indoctrinated with principles of racial superiority. It should be possible for an educational system to inculcate ideas of racial equality with tantamount facility. Children are generally curious, impressionable, companionable, sympathetic, and unselfish. They want to play with their neighbours no matter their status, colour, or religion. They behave instinctively, and only tend to develop class-consciousness, prejudices and prejudices when these are fostered by

No serious attempt has been made to render children fit for the responsibility of citizenship. Arithmetic and literature are crammed into their fertile minds to the exclusion of elementary psychology. How much more harmonious would their lives

become if they were taught something about instincts and emotions. Surely human relationships are worthy of as much attention as geographical and historical data. The study of human nature has been seriously neglected. Children learn something of love, charity, honour, sacrifice, humility, modesty, good, and evil from religious instruction, but this should be complementary to the teaching of simple psychological mechanisms. They should be taught to appreciate the nature of hate, envy, greed, spite, guilt, and temper, so that in later life they will be capable of applying elementary psychology to counter and control these tendencies in themselves and others.

It seems to me that too much effort is directed towards the winning of prizes and coming out top of the class. Competition is a useful stimulus, but as only a few pupils can succeed at the expense of many others, the frustration, feelings of inferiority, and enmity which these successes engender cause greater harm than benefit. Competition in sport also tends to stimulate feelings of rivalry and animosity. The desire to excel, either in athletics or in scholastics, is more determined by neurotic exhibitionism than by worthy self-satisfaction over an achievement which is the reward of painstaking effort and training. We all admire "the best pupil of the year," who frequently combines charm and modesty with outstanding scholastic and athletic performances. He is no exhibitionist, but capital is made out of his achievements, and the emphasis laid on his successes inspires exhibitionist urges and compulsions in less stable personalities. I maintain that this emphasis is harmful. Children should be taught to strive and succeed for the benefits to be obtained from knowledge and physical fitness. Unfortunately their efforts are essentially stimulated by the desire for superiority, aggrandizement, and acclamation.

Failure to educate all children along the right lines may well be the ultimate explanation of much parochial, national, and international strife. Let them be taught, *pari passu* with academic subjects, to understand themselves, their instincts, reactions, emotions, behaviour, and character. Only in this way will they be able to carry enlightenment into the future and undermine the fears, suspicions, and resentments which are always tending to tear the earth asunder. The most careful scrutiny of candidates for the instruction of school-children should be carried out. They should be tested for stability, character, and aptitude. Neurotic types with rigid traditional attitudes and prejudices—whether social, political, or religious—should be eliminated. The experience gained in the selection of officer candidates during the war should be used and improved in order to find the most suitable types of teacher. A watchful eye should be on the look out for behaviour disorders and personality defects in school-children. The advantages to be gained from early reference to the appropriate specialist cannot be over-emphasized. Children are the citizens, parents, and administrators of the future. No effort should be spared in their supervision and training.—I am, etc.,

London, W.1.

ELLIS STUNGO.

"Congenital Malaria"

SIR,—I have followed the recent correspondence with great interest and would like to add these few observations.

It is not generally realized that the incubation period in *P. falciparum* may be as short as five days. There is some, but not conclusive, evidence to suggest that the number of sporozoites injected influences the incubation period. For example, some recent researches have shown that, in M.T., when one million sporozoites are injected fever begins on the fifth day and scanty ring forms are present in the peripheral blood. Whether this number is ever injected into a patient in nature is very doubtful; to obtain this I used an emulsion of dissected salivary glands and the sporozoites were counted before being injected. (See *Transactions of the Royal Society of Tropical Medicine*, July, 1945.) Even in patients infected in the usual manner by the bites of several heavily infected mosquitoes the incubation period is frequently six or seven days. Therefore if the incubation period can be as short as five to seven days in an adult it is conceivable that it may be even shorter in infants.

From the study of hundreds of primary cases infected with M.T. by mosquito bites I have never seen a case where parasites could be demonstrated in the peripheral blood over a period of five days before fever developed. Usually fever

occurs twenty-four to forty-eight hours before parasites can be demonstrated even after a prolonged search of well-stained thick films. These observations are with adults only.—I am, etc.,

Ministry of Health's Malaria Laboratory,
Horton Emergency Hospital.

P. G. SHUTE.

SIR.—Contributors to your columns on the subject of congenital malaria appear to have overlooked the results yielded by chance experiments. These would seem to give strong support to the existence of such an entity. Cases are recorded by Leven (*Maschr. Kinderheilk.*, 1931, 49, 46) and Schadow (*Münch. med. Wschr.*, 1931, 78, 947) where children born to syphilitic mothers who were treated with experimental malaria therapy were found to have malaria parasites in their blood. These cases occurred in areas where natural malaria was non-existent, and would appear to show conclusively that transmission from mother to child via the placenta can occur.—I am, etc.,

Brentford.

E. CRONIN.

SIR.—In this hospital malaria parasites (malignant tertian) have been found on several occasions in the blood of newborn infants, taken from the umbilical cord or subcutaneously. Recently a primipara was delivered of a live premature child (8½-months pregnancy) during an attack of malaria. Blood smears from the maternal surface of the placenta showed ring-form parasites, and subcutaneous blood from the child taken within twelve hours of its birth also showed ring-form parasites.—I am, etc.,

Mission Hospital, Bantyre, Nyasaland.

R. GWEN DABB.

Volvulus of the Small Intestine

SIR.—Dr. W. G. Kerr and Mr. W. H. Kirkaldy-Willis (May 25, p. 799) make this generalization when referring to volvulus of the small intestine: "the condition is relatively common in the East African native"; and Sir Henage Ogilvie (p. 800) makes an even wider generalization by referring to "the proneness of the African to volvulus."

Now Africa is a vast continent with a population estimated in 1944 as 165,348,543 (*World Dominion Press*, 1945), consisting probably of many thousands of separate tribes. Many of these tribes differ not only very markedly in structure and habit but also in the diseases from which they suffer. The epidemiological factors producing these differences cannot be discussed here except to state that they are very imperfectly understood and offer a vast field for research. Recently I have spent five years in Ruanda-Urundi (East Central Africa) and was greatly struck by the difference in the acute abdominal conditions occurring in comparatively near-by hospitals. For example, during my stay I had 17 cases of subacute idiopathic intussusceptions in adults, but did not see one case of volvulus, and I heard of a number of other cases of intussusception in Ruanda-Urundi but no case of volvulus. In 1940 Dr. Dunlop informed me that whereas intussusceptions were extremely rare in the Uganda Government Hospital of Masaka—about 200 miles (320 km.) from us—volvulus of the intestine in women was his commonest emergency. About 100 miles (160 km.) beyond Masaka is the C.M.S. Hospital of Mengo in Kampala. Here, I understand, both intussusception and volvulus are very rare, whereas strangulated herniae and acute retention of urine due to gonorrhoeal stricture are exceedingly common. In five years I saw four cases of strangulated herniae, and only about three cases of acute retention, although gonorrhoea was common.

Thus it will be seen, I think, that the statements quoted in the first paragraph are far too wide to be of any scientific value, and, indeed, are apt to be misleading. In a similar manner Sir Henage's remark "to . . . peptic ulceration . . . he seems to be immune" cannot, from our experience in Ruanda, be accepted unqualified.—I am, etc.,

Old Hill.

T. B. L. BRYAN.

The Catheter and the Prostate

SIR.—I note Mr. Winsbury-White's death rate of 1.05% for suprapubic prostatectomy (June 1, p. 849). Surely we must be dismayed by his death rate of 11.1% for suprapubic cystostomy—that is, if we are to take seriously the expression of mortality as a percentage in so small a series of cases.—I am, etc.,

Cambridge.

TERENCE MCCALL.

"Open Ether"

SIR.—May I add to the many comments on the inability of newly qualified practitioners to administer "open ether" anaesthesia?

I have only recently qualified in South Africa and arrived in England a few months ago; it is a strict ruling at the Medical School of the University of the Witwatersrand that all students before qualifying must give at least 20 anaesthetics themselves with a qualified anaesthetist standing by, and all of these must be "open ether," usually with ethyl chloride induction. Modern machines are available and in use every day; they are demonstrated and students are allowed to assist in their use, but the possible nature of one's work in far-off and primitively equipped places has proved, time and again, the value of the ability to administer an "open" anaesthetic.—I am, etc.,

Cambridge.

D. HAMILTON WALKER.

Judicial Responsibility of G.M.C.

SIR.—The most recent pronouncement by the President of the General Medical Council on the judicial responsibility of that body must give rise to the utmost alarm and despondency. In restoring to the *Register* the name of a practitioner erased as a result of a "gross miscarriage of justice," the President affirmed that: (1) If a practitioner neglects to call all material and relevant evidence he does so at his peril. (2) If there is evidence that is relevant and is not adduced on behalf of the practitioner the responsibility of any adverse view by the Council must rest with the practitioner.

Is not this a circumlocution for "It is up to the accused to prove himself innocent"? And is not this a novel, alarming, and abhorrent view of the responsibility of a judicial body to give fair trial and not to assume guilt until guilt is proved beyond all reasonable doubt?—I am, etc.,

Worcester Park.

ROBERT V. GOODLIFFE.

SIR.—Dr. Hennessy's name has been restored, if somewhat tardily, to the *Medical Register*. This right and proper action is doubtless applauded by all, in view of the gross miscarriage of justice by which the practitioner was deprived of his means of livelihood. One would expect to read of some fitting expression of regret by the President that the General Medical Council should have come to such an erroneous conclusion. But not one word of this is to be heard.

It did not take Mr. Justice Charles many minutes to decide that the evidence of the woman in the case was a tissue of lies, and this he did to a great extent by observing her demeanour in the witness-box. The General Medical Council, on the other hand, swallowed her story, and I doubt if they would have altered their opinion had this "additional evidence" been placed before them at the time. Only one excuse can be offered on their behalf. A judge is trained to detect the false from the true. He is a good psychologist. They are only doctors.—I am, etc.,

Gillingham.

G. E. ELLIS.

Colonial Medical Service

SIR.—There have been for some time such evident signs of dissatisfaction among new members of the Colonial Medical Service (West African) that I think it would help those who contemplate joining it if one with some experience set out some of the conditions to be met in at any rate one West African Protectorate. This letter is not intended to deter men from joining, as there never was a greater need for men of the right stamp, but it is fair to them that they should in some small measure be acquainted in advance with what they are likely to encounter. They can then better make their choice and at any rate enter with their eyes partly open. The prospective medical officer should know that:

1. He will probably not find much private practice. It may be said at once that if a medical officer does his Government work conscientiously he will not have time for private practice.

2. He will probably not find adequate facilities for indulging in a speciality such as surgery (or any special branch of it), research, etc. Working conditions are far more primitive than he is likely to visualize. It should, however, be pointed out that a "specialist" medical officer is not wanted in Protectorate work. The Protectorate medical officer must be a man of parts and able to tackle adequately problems connected with almost any branch of his

profession. A man who "really only does surgery" is of small use to, for example, a district administrative officer. If he is of a specialist turn of mind he should know that the number of specialist posts are now extremely few. He must not expect to be spoon-fed in a Protectorate hospital, and if he does surgery, for instance, must be prepared to supervise the preparation of instruments, etc., himself, as the African staff are quite inadequately trained for this sort of work. If he trains his staff himself and renders a good report on them, he must be prepared to have them seized by head office and to start all over again.

3. He must expect some 33% or more of his time (better spent in improving his medical knowledge) to be taken up with office work. He will have to draft all correspondence himself, "carefully scrutinize" (a favourite head office injunction) all returns, requisitions, pay vouchers, expenditure, etc.—in fact, everything. He will have plenty of reports to furnish. Inspecting and checking Government property, unexpedient and expendable, is also an important part of his duties. In the end he will wonder what on earth the African staff are paid for. It must be borne in mind, too, that his own department is by no means the only one with which he has to correspond. If the Service is to be what it is claimed to be—viz., a medical service—the amount of office work *must* be reduced instead of, as it is, being increased.

4. If he is worldly wise he will concentrate rather on efficiency in office than in clinical work, for in the former lies the road to preferment. If he is still wiser he will qualify to join the Health Department, for to them fall the plums of office. The assumption of superiority by the Health Department has long been a source of wonder and irritation to the clinical medical officer, not eased by the reflection that he does half their work for them in addition to his own. The medical officer could bear the inequity (and iniquity) with composure if he could look forward to some compensation in clinical work within a reasonable period. This inequality must cease.

5. He must realize that the life is more favourable for a bachelor, and must contemplate the possibility of a wife being unable or unwilling to put up with the climate or social conditions. In any case he will be separated from his wife and family for a large part of his career, with the consequent additional expense.

6. He must expect to lead a somewhat nomadic life for his first two or three tours. He will probably (especially during the present shortage of medical officers) be moved, to his intense annoyance, several times in a tour, and at short notice, and see much of his endeavours rendered apparently nugatory and his domestic life disarranged. If he has a car, he may not be able to use it in his next post. But he must realize that it is only fair that the claims of senior officers, who have already been through it themselves, should be recognized, and that his own time will come.

The above may not be a first-class advertisement for the Colonial Medical Service. Nevertheless colonial life has a lot to recommend it in these days of over-civilization. There is still, even in 1946, much pioneer work to be done by men of initiative (if allowed to exercise it), and the work is interesting and not at all monotonous taken as a whole, and the large amount of outdoor life should appeal to many. The prospective medical officer must realize that the Service cannot benefit by all the promising men leaving if *everything* does not suit them personally. It is such men who are needed badly to stay and pull the Service through, but the Government must see that they get all reasonable help. In addition I have always found the Government in personal matters a good and reasonable employer.

Finally, let me put in a last plea for better recognition and better working conditions for the ordinary medical officer. He is the most important man in the department and, so far as the Protectorate public are concerned, the *only* man, and he it is who exercises from the medical or sanitary point of view the only real influence in their lives.—I am, etc.,

"ANOTHER WEST COAST."

Nasal Septal Deformities in Identical Twins

SIR.—The account of nasal septal deformities in a pair of identical twins by Dr. T. O. Howie (May 19, p. 760) was of especial interest to me as only a few weeks before I had had the opportunity of making similar observations. The patients, identical twin boys aged 13 years, were referred to me because of recurrent severe epistaxis. I quote from my records of the cases as follows:

A. B. *Nose*.—Slight septal deflection to the left. Hypertrophy of middle and inferior turbinates on the right side. Usual varicose area on both sides of septum anteriorly—more marked on the left.

G. B. *Nose*.—Deflected septum to the left. Hypertrophy of middle and inferior turbinates on the right side. Degree of impairment of airway on left side. Usual varicose area anteriorly on left side of septum only.

It is evident that, although the intranasal anatomy was not absolutely identical in the twin patients, it showed clear evidence of a similar plan of development. This is not surprising, as perhaps the most striking characteristic about monozygotic twins is the facial resemblance, which of course depends largely on the similar development of the paranasal sinuses and related structures in both. The voices are usually indistinguishable for the same reason.

These patients were also examined by a physician (Dr. Gaisford), and he reported that they both had a similar congenital cardiac defect, a further instance of identical development.—I am, etc.,

Birmingham.

W. OGILVY REID.

D.D.T. Pancakes

SIR.—Your annotation (March 16, p. 398) does not contain a record of any human adult ingesting D.D.T. One of my fellow officers has consumed, as the result of a bet, half a dozen pancakes made of D.D.T. powder instead of flour. He was witnessed by the whole of his mess and enjoyed his meal greatly, without any untoward effects.—I am, etc.,

B.A.O.R.

THERESA LAZAR.

Obituary

W. MCADAM ECCLES, M.S., F.R.C.S.

Surg. Lieut. J. B. GURNEY SMITH, R.N.V.R., writes:

May I pay tribute to a very fine man. Of all Mr. Eccles's great qualities, I feel that his deep-seated interest in the welfare of students in general and of Bart's students in particular and his devotion to medical missionary work were outstanding. These were recognized in his chairmanship of the Student Committee of the B.M.A. and his prominent place on the boards of direction of numerous Christian medical bodies. Of the latter, the Medical Prayer Union, which seeks to stimulate missionary fervour among doctors, was very dear to him. He used regularly to preside at its annual peace-time missionary breakfast held at University College, Gower Street. He was always the ideal chairman in making everyone feel perfectly at ease. I am sure that all past and present members of the St. Bartholomew's Hospital Christian Union will salute his memory, as he was one of the Union's readiest supporters and often took the chair at the annual gathering for freshmen held in the College library. His enthusiasm for all pertaining to Bart's was self-evident, and his absence from the recent celebrations, which he did so much to organize, must have distressed him not a little. His smile and friendly greetings and gracious manner will remain as indelible memories. Truly, a great son of Bart's and a fine Christian gentleman has gone, "the fever of life over and his work done." He has left to all who loved him the shining example of a medical life fired by the highest Christian ideals.

We regret to announce the death on May 27 at Brighton of Dr. DUNCAN DAVIDSON MACKINTOSH of Worthing, who went to practise there after the end of the 1914-18 war. He was born at Aboyne, in Aberdeenshire, on March 16, 1871, son of William Mackintosh, and from Aberdeen Grammar School went to the university of that city in 1888, graduating M.B., C.M. with honours in 1892. He then served as house-physician and house-surgeon at the Aberdeen Royal Infirmary and as medical officer to the Deeside District Isolation Hospital at Aboyne, where he practised for many years. In 1916-19 he was resident medical officer at the 1st London Territorial General Hospital after serving on the staff of the Endsleigh Palace Hospital for officers. Dr. Mackintosh joined the B.M.A. in 1894, was honorary secretary of the Chichester and Worthing Division 1924-32, and represented it at six Annual Meetings. He was elected president of the Sussex Branch in 1936. He leaves a widow, and a daughter who married Mr. Derek Curtis-Bennett, K.C.

Dr. CONWY LLEWELLYN MORGAN, who died on May 28 at Fairlight, near Hastings, had been chairman of the Hastings Division of the B.M.A. in 1924-5, and thereafter represented the Division at five Annual Meetings. Born in South Africa at

Rondebosch on Aug. 6, 1881, son of Conwy Lloyd, M.B., F.R.S., he had his education in England at Clifton College and University College, Bristol, and took his clinical course at St. Thomas's Hospital. He graduated M.B., B.S. Lond. in 1905, and after holding a resident post at St. Thomas's and that of clinical assistant at Great Ormond Street Children's Hospital he proceeded M.D. in 1908. Settling in practice at Hastings, Dr. Morgan was for a time assistant physician to the Royal East Sussex Hospital.

There has passed away recently in Middlesbrough Dr. GEORGE SANDYS BELAS. Until his illness he was senior surgeon to the North Riding Infirmary and chairman of the medical staff. The first half of his professional life was spent in general practice, the second half as consultant surgeon with specialization in genito-urinary surgery. In this latter capacity he was appointed consultant to the E.M.S. Hospital, Hemlington. His services to the St. John Ambulance Association were recognized some years ago by his receiving the honour of Commander of the Order of St. John of Jerusalem. He represented the Cleveland Division of the B.M.A. at the Annual Representative Meeting held at Dublin in 1933 and was chairman of the Division in 1933-4. Belas received his medical education at Trinity College, Dublin, and qualified in 1909. He had many of the best characteristics of the Irishman—good nature, high spirits, and a large degree of the sporting spirit. He excelled at sport himself, having as a student represented the Irish universities in the quarter-mile. He held an enviable position in the affections of his fellow practitioners and was very popular with the public, while at the same time maintaining a personal dignity that supported his position as a medical man. He leaves a widow and three sons, one of whom has recently taken his degree of M.B.

We regret to announce the death of Dr. AUBREY DALLAS PERCIVAL HODGES, C.M.G., late lieutenant-colonel in the Uganda Medical Corps, who was principal medical officer of the Uganda Protectorate, 1908-18. Son of Dr. H. B. Hodges of Watton, Herts, he was born in 1861 and was educated at Epsom College and the London Hospital, where he held three resident posts, and then became assistant R.M.O. at the South-East Fever Hospital, New Cross. He had graduated M.B. Lond. in 1890 and M.D. two years later. During his service in East Africa Dr. Hodges was for a time medical officer in charge of an extended investigation into trypanosomiasis and was A.D.M.S. for Uganda in the war of 1914-18. A colleague writes: "Apart from his skill as a doctor and administrator of his department, he was a scientist and naturalist of no mean order, and his research into the habits and life history of the tsetse fly did much to solve the problem of dealing with the fly and the control of sleeping sickness in early days. He will also be remembered for his hospitality and the genial atmosphere he created wherever he was."

Major COLIN CAMPION, R.A.M.C., who died recently at sea after a short illness while on a troopship, was the son of Mr. Ernest Campion, of Isleworth, Middlesex. While a student at St. Bartholomew's Hospital he won a junior scholarship in chemistry, physics, and biology, and junior and senior scholarships in anatomy, physiology, and chemistry, and also the Herbert Paterson gold medal in biochemistry. He graduated M.B., B.S. Lond. with honours in 1943, and had been house-surgeon at Bart's and resident medical officer at the Hampstead General and North-West London Hospital before taking a commission in the R.A.M.C.

The Services

Surg. Lieut. J. G. Reed, M.R.N.V.R., has been appointed M.B.E. (Military Division) for outstanding services while a prisoner of war in the Far East.

Surg. Lieut.-Cmdr. J. A. Page and Surg. Lieut. J. P. Corcoran, R.N., and Temp. Surg. Lieut.-Cmdr. A. P. Curtin, R.N.V.R., have been mentioned in dispatches for good services while prisoners of war in the Far East.

Majors (Temp.) H. M. S. G. Beadnell and C. W. Maisey, R.A.M.C., have been mentioned in dispatches in recognition of gallant and distinguished services in Java in 1942.

Capt. I. Shragovitch, R.C.A.M.C., has been mentioned in dispatches in recognition of gallant and distinguished services in Italy.

CASUALTIES IN THE MEDICAL SERVICES

Killed in road accident in Middle East.—Capt. Edmund Timothy Gurney Meade-Waldo, R.A.M.C.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The Senate, on the recommendation of the Council, has resolved to confer the degree of Doctor of Science, *honoris causa*, on Sir Henry Tizard, F.R.S., President of Magdalen College, Oxford; Mr. C. J. Mackenzie, president of the National Research Council of Canada; Dr. C. H. Best, F.R.S., professor of physiology and director of the Banting-Best Department of Medical Research in the University of Toronto; B. F. J. Schonland, Ph.D., F.R.S., president of the Council of Scientific and Industrial Research of South Africa; and Dr. F. M. Burnet, F.R.S., director of the Walter and Eliza Hall Institute for Medical Research, Melbourne; also to admit J. N. Mills, D.M.Oxon, Fellow and lecturer of Jesus College, to the degree of Doctor of Medicine by incorporation.

During May titles of the degrees M.B., B.Chir. were conferred by diploma on G. C. Thompson, of Newnham College.

UNIVERSITY OF LONDON

The report of the Principal on the work of the University during the year 1945-6 is dated May 2. Among many matters of interest it recalls the innovation by which the Treasury grant for the current academic year to the University Grants Committee was £500,000 for transmission to teaching hospitals. So far less than half this sum has been allocated, on the basis of the clinical entry to medical schools in 1944-5, and London University's share was a little over £94,000. Several grants for teaching and research purposes were received, including financial support from the Wellcome Trustees to institute a part-time chair of tropical medicine, tenable at the London School of Hygiene and Tropical Medicine. The Medical Research Council has made a grant for the establishment of a chair of human nutrition, also tenable at that School, to which Dr. R. S. Platt has been appointed. Newly appointed deans of undergraduate medical schools include Dr. C. F. Harris at St. Bartholomew's, Dr. E. R. Boland at Guy's, Dr. D. H. Brinton at St. Mary's, and Dr. K. Lloyd Williams at the London School of Medicine for Women. "Finally, we welcome Sir Francis Fraser as the first director of the British Postgraduate Medical Federation. Under his guidance will be built up an organization which will co-ordinate and develop all the general and specialized facilities for postgraduate medical education in London." During the academic year the title of reader in pharmacology was conferred on Dr. H. O. Schild. Dr. John Yudkin was appointed to the chair of physiology at King's College of Household and Social Science, and the title of reader in human nutrition was conferred on Dr. Gladys Hartwell. Dr. J. N. Davidson was appointed to the chair of biochemistry at St. Thomas's Hospital Medical School. At University College Hospital Medical School Prof. Wilson Smith has been appointed to the chair of bacteriology and Dr. Walter Fruedenthal to the readership in dermatological histology. At the College of the Pharmaceutical Society Dr. G. A. H. Buttle was appointed to the chair of pharmacology; at the Royal Cancer Hospital Prof. E. L. Kennaway is retiring from the chair of experimental pathology and will be succeeded by Dr. Alexander Haddow. The title of professor emeritus was conferred on Dr. G. W. de P. Nicholson, who held the chair of morbid anatomy at Guy's Hospital Medical School from 1922 to 1944. In his report for 1944-5 the Principal referred to the special committee set up under the chairmanship of Sir Henry Dale to confer with the undergraduate medical schools on the question of the admission of women students. He now writes: "That committee has now completed its work, and I am glad to be able to report that all the medical schools concerned have signified their willingness to accept women students, and the London School of Medicine for Women has agreed to accept men students."

The following have been recognized as teachers of the University in the subjects indicated in parentheses:

St. Thomas's Hospital Medical School: Dr. R. W. John (Morbid Anatomy); Dr. J. L. Pinner (Pathology); Dr. J. L. Pinner (Physiology); St. George's Hospital Medical School: Dr. G. Edwards and E. F. (Surgery); Middlesex Hospital Medical School: Dr. A. E. W. Idris (Anaesthetics); University College Hospital Medical School: Dr. H. N. Webster (Anaesthetics); Lister Institute of Preventive Medicine: Dr. D. M. (Physiology); St. Mary's Hospital: Dr. L. Minns and A. B. Stokes (Physiology); Society of Medicine: Dr. Marthe Vogt (Physiology); Dr. H. F. Rosenberg and O. G. Edholm (Physiology).

Candidates for the M.B., B.S. who passed the second examination for medical degrees in or after March, 1945, will be required to have attended not less than 30 months' course before entry for Part I and not less than 36 months' course before entry for Parts II and III of the M.B., B.S. examination. Arrangements relating to pharmacology at the second examination for medical degrees, under which pharmacology is a separate subject in which candidates may be referred, and an additional examination in pharmacology only is held in

September, was approved "as a war measure." They will be continued for the present, but the matter is to be further considered in October. Additional examinations for the Academic Postgraduate Diploma in Medical Radiology will be held in the session 1946-7 for students who attend the course for the diploma which began in April.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of the Council, held on May 25, with the President, Mr. Eardley Holland, in the chair, the following were formally admitted to the Fellowship:

A. C. H. Bell, J. L. Cameron, Mabel F. Potter, D. M. Stern. *In absentia*: E. Keelan, N. W. Philpott.

The following were formally admitted to the Membership: Constance L. Beynon, E. W. C. Buckell, W. Calvert, R. G. Cross, G. Dalley, Perla Greeves, Emilie E. Guthmann, W. P. Hirsch, W. Kearney, A. H. C. Walker, Margaret Weddell. *In absentia*: S. N. Garde.

The Council acknowledged with grateful thanks a gift of £1,000 from Sir William Fletcher Shaw to found a lectureship in memory of his son William Meredith Fletcher Shaw, who fell in Normandy in 1944, to be awarded annually to a senior Fellow of the College.

At the annual general meeting of the College, held on May 25, with the President, Mr. Eardley Holland, in the chair, the following were elected to Council in place of those retiring by statutory rotation: *Representative of the Fellows*: R. H. M. Corbet, A. A. Gemmell, A. J. McNair, E. Farquhar Murray. *Representative of the Members*: B. L. Jeaffreson, J. S. Quin. Prof. Hilda Lloyd and Mr. L. C. Rivett were co-opted to the Council for special purposes.

Medical Notes in Parliament

HEALTH SERVICE BILL

Towards the end of the discussion in Committee on May 30 Mr. KEY, in reply to a number of questions, said that the Minister intended that there should be a standing advisory committee on hospital services and that the position of Wales as a region and the relationship of North and South Wales were matters for consultation when regional areas were set up. Clause 11 as amended was ordered to stand part of the Bill.

FUNCTIONS OF BOARDS AND MANAGEMENT COMMITTEES

On Clause 12 Mr. KEY moved to insert words making clear that the Minister was not required to carry out his duties, in providing hospital and specialist services, exclusively through the Regional Boards, but might provide those services direct. The amendment was accepted.

Mr. LAW asked the Committee to delete the reference to "directions given by the Minister" in the provision that the Regional Board must administer the hospital and specialist services in the area "in accordance with regulations and such directions as may be given by the Minister." These words, he said, were objectionable both in this instance and whenever they occurred, which they did frequently. A peculiar character of the Bill was the Minister's wide powers, which he could exercise without responsibility to Parliament or to anyone. The Minister could claim freedom of action, but it should be subject to the approval of Parliament. Mr. KEY said that in the administrative work there might be occasions when it would be necessary to give directions to Regional Boards outside the regulations. Parliament could always call the Minister to book about these directions.

After further debate Mr. LAW's amendment was rejected by 22 to 14 and the Committee adjourned.

On June 4 proceedings began with an amendment, moved by Mr. LIPSON, to vary the wording of Clause 12, subsection 1 of which defines the duties of a Regional Board and subsection 2 authorizes the Management Committee to exercise such functions of the Board as might be prescribed. He proposed first that the Board should appoint such officers as were necessary; and, secondly, to omit the provision that the Board should maintain premises associated with any hospital other than the teaching hospital and could acquire and maintain equipment, furniture, and other movable property. His amendment provided for transfer of these powers to the Management Committee in accordance with regulations and directions given by the Minister. He also proposed that the Management Committee should appoint officers required to be employed at or for the purposes of the hospital, except specialists, and should appoint for each hospital in a group a house committee to which could be delegated any of the Management Committee's functions for each hospital. Mr. LIPSON said the amendment was not intended to weaken the status and authority of the

Regional Board because it gave the Board power to appoint its own secretariat. He could not discover in the Bill what was to appoint officers of the Regional Board, but prestige influence would be added to the Board if it had power to appoint its officers. If the Management Committees were to represent local knowledge and local influence they must have powers equal to their responsibilities.

Mr. WILLINK said Mr. Bevan had moved a little in the direction of giving real responsibility to those who were responsible for the day-to-day work of hospital groups by promising to introduce amendments which would make the Management Committees into legal "persons" capable of receiving legacies and gifts. To maintain local responsibility and feeling the amendment proposed to remove from the Regional Board the functions of appointing officers—nurses, stokers, etc.—to be employed at any hospital in the region. A nurse would be more attracted to be one of the staff of a great hospital group rather than become one of thousands of officers of, say, the North-West Regional Board. He asked Mr. Bevan whether the Bill intended that the Regional Board was to appoint all officers, or did it merely provide that the Board had a duty to appoint such officers as were not otherwise appointed? Would it be the duty of the London Regional Board to appoint all the officers required at, say, the Hospital of St. John and St. Elizabeth? The chairman of the Nuffield Provincial Hospitals Trust had expressed the view that in hospital management every person in the hospital should be in contract with, and be an officer of, the Management Committee, with the exception of the specialist. The Minister should provide for house committees in the Bill, as proposed in the amendment and as he had included in the White Paper.

Dr. CLITHEROW said he had sat on a voluntary hospital board when a matron was appointed by the Board in face of opposition from the medical men. In six months the lay committee was shown to have been wrong. That would not arise under a Regional Board. Mr. SOMERVILLE HASTINGS said the Committee must not forget the danger of another voluntary hospital system growing up within the administration of the Regional Boards. If the Management Committees were to have the best people working with them they must have powers to make quick decisions and to experiment, but he saw danger in their appointing any but the junior staff. He was chairman of the staff subcommittee of the Hospitals and Medical Services Committee of the L.C.C. When a senior appointment was made at any L.C.C. hospital the subcommittee invited the opinion of the chairman of the hospital. In nine cases out of ten the recommendation was for an individual who had been at that hospital. This also applied to voluntary hospitals. He himself was an example of that danger, because he had never left the hospital at which he was a medical student.

AVOIDING "EXISTING ANARCHY"

Mr. BEVAN said those who complained of the dangers of a rigid health service were those who moved amendments putting the service into the strait-jacket of a Statute. The Committee was starting something experimental which might require modification from time to time, and this would be impossible if every time modification was wanted the Ministry found it was kicking its shins against words in the Bill. The Committee was organizing a service, not defining a statutory contractual relationship. He sympathized with the purposes of the amendment, and the schemes would not be approved unless there was considerable devolution of responsibility to the Management Committees. Domestic and junior staffs would be appointed by the Management Committees but would be in contract with the Regional Boards. It would not be right for Management Committees to use their powers to have differential incomes for workers doing the same work in hospitals in the same region. That would re-create the existing anarchy in the hospital service. One of the reasons local hospitals were not as good as they ought to be was that they were too much under local influence and too little under the influence of the medical schools. Greater mobility within the service would be achieved if officers were in contract with the Regional Board and not the Management Committees. At present medical workers and hospital staffs were enchained by their particular institutions. He had met several deputations of workers, who complained that their possibilities of promotion were almost negligible because they were limited to the institutions in which they now worked.

Sir H. MORRIS-JONES said that under Mr. Bevan's proposal general practitioners would function under two bodies. On the one hand the executive committees would be their employers, and on the other hand they would be appointed to the hospitals by the Regional Boards. That was an anomaly. Mr. MESSER said he understood responsibility being delegated to select up to a certain standard of staff, but after that there

must be a selection body, such as existed in some big counties, which would ensure a certain standard of medical staff, composed of members of the medical profession. It was essential that nurses should be identified with a particular hospital.

Mr. BEVAN replied that Mr. Lipson was harbouring an unjustifiable fear; "it would be stupid for the Minister to appoint the officers of the Regional Boards; how would it be possible for the Boards to function properly if they were puppets of the Minister?" Mr. Messer had described admirably what would happen in practice. Certain ranks of staff would be appointed by the Management Committees with no reference to the Regional Board. For staff higher up the Management Committees would make recommendations to the Regional Boards, which the latter would usually accept. The amendment was defeated by 27 to 14.

Mr. PIRATIN moved to add to the powers of the Regional Boards the duty to provide for the training of all types of health workers, other than doctors. Mr. BEVAN said it would be an obligation on the Regional Boards to train such health workers as were not trained by other institutions. Mr. Piratin withdrew his amendment.

Mr. RANKIN moved to add a proviso that the M.O.H. should act as epidemic officer for the area under the Regional Board. Mr. BEVAN said the hospital service would be at the disposal of the local authority for all its purposes and therefore there was no need to appoint an epidemic officer in an area. The amendment was withdrawn.

STAFF COMMITTEES DEFINED

In subsection 2 Mr. SOMERVILLE HASTINGS proposed a change of words to provide that hospitals which were attached to the Regional Board need not be in the same region. If the Minister decided that the L.C.C. should be a region, none of its mental hospitals would be in the county. Mr. BEVAN said the amendment was unnecessary, because a Regional Board was a congeries of hospitals and it would be possible for the geographical area of London to reach out and take in any hospital necessary for its purposes. He was not prepared to give an assurance that the L.C.C. area would be a region. In one area there might be a considerable number of fever hospitals or of mental hospitals and in another area very few. There might be two Regional Boards astride these two areas. The word "area" included the power for a Regional Board not possessing a particular institution to take in such other hospitals as were necessary to complete its services. The amendment was withdrawn.

Dr. MORGAN moved an amendment to make a statutory provision that for every hospital under a Management Committee a medical staff committee should be appointed to work in conjunction with the management. Dr. STEPHEN TAYLOR asked the Minister to consider having medical and other health staff committees. Mr. BEVAN replied that if the Bill said there should be a particular staff committee the implication would be that there were to be no other staff committees, or that one staff committee had a higher status than others. It was intended to have staff committees of all the health workers in hospitals. He hoped the Committee would not regard medical workers as different from other workers. Dr. Morgan accepted the assurance and withdrew his amendment.

On the motion that Clause 12 stand part of the Bill Mr. LINSTAD said that Clause 41 contemplated that all officers employed for providing hospital and specialist services should be officers of the Regional Board. It was also contemplated that local authorities when they provided health centres should not themselves employ the medical staff. Clearly the executive council were not to employ the specialists at the health centres. Ought not some provision to be made whereby specialists at health centres were declared to be on the regional staff and not on a local authority staff or an executive council staff?

Mr. PIRATIN asked for an assurance about the Regional Board's planning responsibilities. Clause 12 limited the responsibility of Regional Boards and Management Committees to administration. The explanatory memorandum said each Regional Board "in collaboration with the Minister and with the teaching hospitals would plan, and execute the plan for, a co-ordinated hospital and specialist service for its region." He found no reference to this in the Bill.

THE MINISTER'S "DIRECTIONS"

Mr. WILLINK said there now stood in Clause 12 three provisions for directions which could be given by the Minister: directions to the Regional Board in general terms; to the Management Committee by the Minister or the Regional Board; and to the board of governors of every teaching hospital. During the war medical "directives" were issued in connexion with the E.M.S., but he believed that in the Clause

the true meaning of the word "directions" was in the administrative sense, and anxiety would be relieved if the Minister gave an assurance that he was not taking powers to give directions of a purely medical character to his medical officers. Dr. MORGAN added that during the war directions or guidance sheets about dosage and things of that sort had been issued to hospitals. In the E.M.S. that was only done subject to the discretion of the medical officer in charge of the case; it had never been regarded as compulsory that the medical officer must be guided by the direction.

Mr. BEVAN said that specialists employed at a clinic would be in contract with the Regional Board except in so far as they would be employed by the local health authority under Clause 61. He could give no assurance that medical officers of health would be put in any special relationship with the health service; they would carry on their responsibilities as at present except as these were modified by the provisions of the Bill. There would be no difficulty about the medical officer getting from the hospital system the services he required; because these services were at the patient's disposal. He (Mr. Bevan) had already stated specifically that he wanted Regional Boards appointed soon so that they might set about planning. With regard to directions, the intention was that they should be administrative and not medical. The Minister would not accept the odium of giving directives about any particular form of therapy. That was a matter for the professional man without any interference, directions, instructions, or prohibition.

Clause 12 was ordered to stand part of the Bill, as was Clause 13 on the legal status of Boards and Management Committees.

MACHINERY FOR APPEALS

On Clause 14, which deals with conditions of service and appointment of officers, Mr. LINSTAD moved to add a subsection to provide machinery for dealing with dismissals or with complaints made against officers or doctors employed by Regional Boards and to provide for appeals against such dismissals. He said the medical profession were apprehensive about their position when a large number of them had become, in effect, State servants. If they became liable to be "shot at" by patients there ought to be clear machinery which would satisfy doctors that, in the event of complaints or dismissal by a Board, they would be able to appeal and have opportunity to state their case. Mr. BEVAN said there was provision for dealing with the dismissal of general practitioners and there would be a special tribunal for dentists. He doubted whether it was necessary to have a tribunal for specialists, because they were under a different kind of contract and he doubted whether they would desire it. If it was found on investigation that a specialist had been guilty of misconduct in a professional matter there would be the professional tribunal to deal with it.

Mr. Linstead withdrew his amendment and Clause 14 was added to the Bill. Clause 15 was also added to the Bill without discussion.

On Clause 16, which gives the Minister power to aid research, an amendment from Col. Stoddart-Scott was accepted to add "causation" of illness or mental defectiveness to the subjects of research which the Minister may conduct or assist. The Clause as amended was ordered to stand part of the Bill, as was Clause 17 providing bacteriological service. On Clause 18 Mr. BEVAN said the Ministry proposed to set up a standing advisory committee on which blood donor organizations would be represented for continuous consultations. This was not a private enterprise carried on for profit.

Further consideration of the Bill was then adjourned.

On June 5 the Committee discussed Clause 19 and accepted a drafting amendment proposed by Mr. Key to secure that local authorities could be formed into joint authorities for the purpose of carrying out health functions other than those mentioned in the Bill, such as those connected with the Lunacy and Mental Treatments Acts and the Mental Deficiency Acts.

POWERS OF THE L.C.C.

In the same Clause Mr. WILLINK moved an amendment to re-define the application of the Clause to the administrative county of London. He said the main purpose of the amendment was to provide for a division of functions between the L.C.C., the Common Council of the City of London, and the councils of the 27 metropolitan boroughs and the city of Westminster. The change which Mr. Bevan proposed to make in administration of health services in London went far towards destroying local government in London. In the Clause maternity and child welfare work, the work of health visitors, and the new functions with regard to home nursing would all go to the enormously overburdened L.C.C., consisting of 120 elected councillors. The amendment suggested that health services could all be functions of the L.C.C., but that the

administration of those which were of a particularly personal kind should be delegated by statute to the 29 authorities which he had mentioned. The Minister had come to an unfortunate decision to nationalize all hospitals, including L.C.C. hospitals. Mr. Willink suspected that the L.C.C. had received additional functions as a *quid pro quo* for losing the hospitals. He contended that healthy government in London could be restored only by increasing the local patriotism of the old communities which made up the metropolis.

Mr. KEY said Mr. Willink's speech had not been directed to the problem which the Committee had in hand. Medical inspection and care of school-children rested with the education authority—which was the L.C.C. The Government scheme brought maternity and child-welfare care in with that service, and by giving it to the same authority would lead to greater efficiency. Mr. Willink's scheme would divorce the maternity and child-welfare service from the midwifery service, which was to be maintained and provided by the L.C.C. By making the L.C.C. the authority for the health services that were being provided, London would secure services of a proper standard despite the rating poverty of particular areas; it was in the interests of the health of the people of Poplar, Shoreditch, and Bethnal Green.

Mr. BEVAN said the amendment asked the L.C.C. to consider functions in relation to the metropolitan boroughs without considering its obligation to all the population which was contiguous. The population of London was undergoing a big redistribution, which must affect the functions of the L.C.C. and the metropolitan boroughs. Once the Ministry admitted that London metropolitan boroughs ought to be health authorities under the Bill it would create an argument of a similar kind for non-county boroughs in other parts of the country. He agreed that the L.C.C., if it attempted to carry out its functions under the Bill without co-operation from area committees and metropolitan boroughs, would soon become over-centralized. The L.C.C. would arrange a scheme by which there would be area committees in London on which the metropolitan boroughs would be represented for the purpose of carrying out certain functions, but these committees would not have delegated powers. They would have agreed responsibilities.

After further discussion the amendment was defeated by 23 to 17, and the Clause was added to the Bill.

PUBLICITY FOR LOCAL PROPOSALS

On Clause 20 Mr. Linstead moved an amendment to ensure publicity in the press for the proposals relating to health services which health authorities must send to the Minister. Mr. BEVAN believed that insistence on the admission of the Press into meetings would serve better. The amendment was rejected by 24 to 14. Mr. Linstead withdrew an amendment which suggested that the local health authority should also submit its proposals to the minor local government authorities within its area. Clause 20 was then added to the Bill.

HEALTH CENTRES

On Clause 21 Mr. BEVAN moved the adjournment after Mr. Willink had opened a discussion upon amendments designed to provide that in every case the local health authority could make representations as to the desirability of the provision of health centres, and that the Minister should consider the point of view of the Regional Board.

When consideration was resumed on June 6 on an amendment proposed by Mr. WILLINK it was agreed to have a general debate on health centres.

Mr. Linstead said that paragraph 42 of the White Paper stated that the object of the general scheme was that the health centre system should afford facilities for general medical and dental services, special clinic services, and "outpost" clinics of the hospital and specialist services, and also serve as a base for activities in health education. The health centre was a new conception of a focus for health services which had not yet been developed in this country, and the proposals in both the Bill and the White Paper tended to go too far and too fast. We did not know how far the idea of a health centre would appeal to the general public. They had to be educated to the idea of going to a public centre every time they wished to see their general practitioner. Administrative difficulties, too, could be too easily overlooked. The health centre would be a place where the hospital service run by the Regional Board, the local authorities' service, and the general practitioner service run by the local executive council were all to meet. At least three administrations would meet in the same building. The health centre might be a hive of industry but it would also be a hornets' nest. The patient would rather see his general practitioner, at least for the first interview, in the general practitioner's own consulting room on terms of friendship and informality. Health centres with full diagnostic facilities were required, for the weakness of the general prac-

itioner service at present was the difficulty of getting these facilities. The White Paper did not make clear what type health centre was contemplated. Much had been heard of health centres as places where groups of general practitioners got together; such a health centre was little better than a communal consulting room. What the public and the doctor would prefer was a private consulting room elaborated to proper modern standards, with, very close behind it, a well-equipped health centre—a diagnostic centre—where the general practitioner could send, it might be, a quarter of his patients for a second examination. He hoped the Minister would assure the Committee that there would be a good deal of experiment before public money was directed into any particular form of health centre.

Cmdr. MATTLAND said that in the countryside the three administrative functions mentioned by Mr. Linstead were performed by one man and would be so performed for some time. He asked whether in the country beds would be provided at these clinics. Would there be facilities for emergency operations? He asked the Minister to give a full exposition of his ideas, and hoped that at the same time he would ensure that it did not go out from that Committee that all country doctors posed as specialists and that all hospitals were run by matrons for their own ambitions. Mrs. RIDEALGH asked whether the Minister intended that all health centres should have child-guidance clinics.

ONE DISADVANTAGE OF HEALTH CENTRES

Dr. STEPHEN TAYLOR said the general practitioner service in the Bill would stand or fall by the success of the health centres. In the past the general practitioner had felt that the clinic was taking away his patients. If the doctors were operating under the same roof they would be colleagues. The progressive general practitioner recognized the value of team-work, and some successful general practices had multiple surgeries where the doctors had installed x-ray plants, dispensaries, and so on under a common roof. That had been done in Winchester and a number of other large towns. To educate the public to visit these centres was not difficult, because a great part of the public already visited clinics or, unfortunately, the outpatient departments of voluntary hospitals, which they used as general practitioners' centres. He thought they agreed that the doctor should have his own consulting room at the health centre, and there could be an appointments system for patients. The health centre had one obvious disadvantage. If four, five, or more doctors were grouped together any patient would have to travel a greater distance to get to his own doctor. That should be minimized by the proper siting of centres. He hoped to see the educative function of the health centre developed. In the past doctors had felt they must not talk about professional subjects; they should take the patients more into their confidence. He hoped there would not be beds in health centres. Captain BAIRD asked for an assurance that the health centre would not be provided solely for general dental services.

Dr. BARNETT STROSS said he was happy to note that the Clause said each health centre must be provided, equipped, and maintained to the satisfaction of the Minister. If the doctor who practised in the health centre became a health servant rather than a sickness servant he would want additional instruments, some of which he had never had in the past, and also a lecture hall and the opportunity of educating his patients on how to prevent themselves getting ill. He would not require in the immediate future to compete with the consultant or specialist, and the provision of x-ray apparatus, operating theatres, beds, and so on was very debatable. But there should be pathological services on the premises of any reasonably sized health centre. Dr. CLITHEROW associated himself with the subsequent amendment put down by Mr. Linstead as to pharmacists to the persons who, by a proviso to Clause 2 must not be employed by a local authority at health centre for the purposes of providing medical or dental services. He said that pharmacists preferred to come under the Regional Board as being professional men, and he hoped the Minister would think well before he forced them to be officers of local authority. Dr. Clitherow also drew attention to another amendment in his name which would permit the provision in health centres of "general ophthalmic optical services by optical practitioners."

Mr. MESSER said local authorities' organizations viewed with disquiet the administration which was outlined in the Bill. The local authorities were responsible only for the preventive and not for the remedial services, yet they were to be the administrators of the health centres. They were to provide and equip them. Who was to decide the range of equipment? It was a bad principle that the user of a health centre should not also be the authority responsible for its control. For that reason the local authorities felt it would be wise if control were in the hands of the Regional Board and, if necessary, the local

authorities could obtain permission from the Regional Board to use the centre under the Management Committee of the hospital.

Mr. J. S. C. REID asked what priority of building the Minister would give to these health centres. In the White Paper there was a phrase about using the health centres as "outposts" for hospitals. Nothing in the Clause would entitle the local authority to lay out any part of a health centre for that purpose. He saw nothing in the Bill to link up the health centre with the Regional Board. He thought the matter should be examined again. If records were to be kept in the health centre by a local authority employee the public would want clear assurance and strict regulations that these records were not made available beyond the doctor who was looking after that particular patient.

INTELLECTUAL ISOLATION OF THE G.P.

Mr. BEVAN said there was much controversy about health centres, but no controversy about the need to establish them. The only way in which the intellectual isolation of general practitioners could be broken down and a higher standard in the service built up was by bringing independent practitioners into intimate and frequent contact with their fellow doctors. Doctors had told him how much keener they were because they had been brought into association with each other in the E.M.S. There would be no experimenting with the initial idea of health centres; only experiments on how the idea was to be carried out, for instance, with regard to building. The centre must serve a fairly large unit of population. They could not have expensive diagnostic apparatus in each street. They were looking forward to a healthy population, and that was why it was necessary to give more attention to the preventive side of medicine. At every large health centre there should be opportunities for doctors to talk to children, to mothers, and to separate sections of the population about their particular problems. If they could get a stream of healthy people attending the centre it became a real health centre. One of the chief drawbacks of the out-patient departments of hospitals was that everybody in them was sick. Everybody had something wrong. All sorts and sizes of people sat on squalid hard benches for hours waiting for tired doctors to attend them. It was an appalling atmosphere. What the Government had not been able to make up its mind about was whether the country was to have health centres providing a variety of services, or rudimentary consulting centres nearer to people's homes where five or six general practitioners attended with comparatively rudimentary apparatus, and from which the doctors could send their patients for more extensive examination to health centres. The latter method would probably be the one for rural areas, where they would not be able to provide a large number of fully fitted health centres.

Lord WILLOUGHBY DE ERESBY asked whether the way out of the difficulty was to encourage doctors to develop their own surgeries. Mr. BEVAN: We do not want them to do that. We want them to get away from their surgeries and mix with each other.

MORE PARTNERSHIPS WANTED

Continuing, Mr. Bevan said the Ministry would be ready to encourage larger groups. It wanted more partnerships. The service must be a national one; to allow local authorities to experiment themselves with health centres would permit backward local authorities to deny their citizens health facilities. The first priority must be houses, and hospital facilities must come second because in some parts of the country there were long waiting lists and scarcely any possibility of patients being seen. But there were places where health centres could be established quickly. He did not suggest that this could all come into operation on the appointed day. It would have to be a growing service, adapted from year to year as experiences dictated. Mr. Reid was wrong when he said the Bill contained nothing to provide specialist services at health centres. Clause 3, Clause 61, and other Clauses provided the Minister with all the authority he needed. If they did not the Government would amend the Bill. Dental clinics would be at the health centres because the Ministry did not wish them to be separated from the rest of the health services. He had been asked about opticians and ophthalmologists; if facilities were available and if there were enough ophthalmologists it was desirable that anybody who felt that he or she had something wrong with their eyes should see the ophthalmic surgeon first. If spectacles were required the eye-testing optician provided them.

Dr. CLITHEROW thought the examination of eyes first by an ophthalmologist was a gigantic requirement. Mr. BEVAN said that opticians would not be under greater disabilities than other employees of local authorities. He could not agree to health centres being provided by the Regional Boards. These Boards were much too wide. It was far better for the local

authorities to have these functions. He agreed that large numbers of people wished to be assured that there would be complete privacy, for confidences they reposed in their doctor. There was no intention of mutilating that tradition. What the Ministry wished to avoid was the patient having to go through the same painful diagnosis by different doctors because his medical history was not available.

Mrs. RIDELGH asked about child-guidance clinics at health centres; many of the sufferings of backward and delinquent children were caused by physical defects which were undiscovered unless the child was seen by a psychiatrist. Mr. BEVAN could not promise that every health centre in Great Britain would be staffed by psychiatrists. There was a great shortage of trained psychiatrists. Numbers of people who had learned the nomenclature of psycho-analysis were masquerading as psychiatrists. The guidance given at the health centre should be skilled. Later the medical service of the schools would be assimilated into the National Health Service and that branch could be expanded.

Mr. WILLINK hoped the Minister was satisfied that the wording of the Bill would enable him to prevent an unwise local authority building six unsatisfactory health centres when they should build two good ones. He was reassured by what Mr. Bevan had said and was prepared to withdraw the amendment.

The amendment was by leave withdrawn, and Mr. Linstead moved one in the same Clause to transfer the pharmaceutical service in the health centres from the supervision of the local authorities to the supervision of the local executive councils. After some discussion this amendment was withdrawn.

On the motion that Clause 21 stand part of the Bill, Mr. BEVAN, replying to Mr. Willink, said it was intended that all V.D. services and clinics should be taken over by the Regional Boards. The Clause was ordered to stand part of the Bill.

Service Hospitals and the Bill

Mr. HARDY on May 30 reported grave concern at the disabled persons' and Servicemen's hospitals and homes not being included in the national scheme for hospitals. Mr. KEY said the hospitals which were subject to the provisions of the Health Service Bill and would normally be included in the future service were local authority and all other hospitals which were not provided by some other public authority and were not run for profit. The relationship to the general service of hospitals belonging to other Government Departments would be a matter for later consideration.

Cancer Research Expenditure

Replying on May 30 to Col. Byers, Mr. HERBERT MORRISON said the amount already allocated to cancer research out of the grant-in-aid to the Medical Research Council for 1946-7 was £7,600. It was not possible to forecast what additional expenditure on the subject would be incurred during the year, but no promising research proposal would be declined owing to lack of funds. This allocation of public money was supplementary to the substantial expenditure from the endowments and other resources of unofficial bodies and institutes existing specially for the purpose of research into cancer.

Invalidity and Pension Awards.—Mr. WILFRED PALING states that from the outbreak of war to April, 1946, the number of officers and other ranks invalided from the Forces and dealt with by the Ministry of Pensions is approximately 720,000. Awards have been made in nearly 315,000 cases. In over half the cases where no award has been made the man concerned has at no time inferred a claim. From persons released from the Forces 64,000 claims have been received. Awards have been made in nearly 42,000 cases, 10,000 claims have been rejected, and 12,000 are under consideration.

Conscription Period.—Mr. ISAACS announced on May 30 that young men reaching the age of 18 and called up for the Forces in 1947 would serve for two years. If no unforeseen circumstances arose, this period would be progressively reduced for those called up during 1948. The arrangement for students during 1946 was as announced on April 30. Definite arrangements have not yet been made for 1947, but it was hoped to make the same arrangements.

Release from R.A.F.—Sir E. GRAHAM-LITTLE on May 30 inquired about the release of medical officers of the R.A.F. He pointed out that by July these officers would be about 10 groups behind the Navy. Mr. DE FREITAS said the release of medical officers of the R.A.F. was slower than in the other two Services because the wartime proportion of medical officers in the R.A.F. had been much lower than in the Army or Navy. The Air Ministry was doing all it could to increase the intake in order to reduce the differences, but he could not forecast when approximate equality between the Services would be reached.

Notes in Brief

The Control of Penicillin (No. 1) Order, 1946, made by the Ministry of Supply, was presented to Parliament on May 28.

Medical News

A Chadwick Lecture on Plants in the Service of Mankind will be given by Miss Ellen M. Delf, D.Sc., on Thursday, June 20, at 4 p.m., at the Chelsea Physic Garden, Swan Walk, S.W., when Sir William J. Collins, M.D., chairman of the Chadwick Trustees, will preside.

The annual meeting of the Faculty of Radiologists will be held in Glasgow on Friday and Saturday, June 28 and 29. At the annual general meeting on June 28 in the Lister lecture theatre of the Royal Infirmary the president, Dr. Ralston Paterson, will take the chair for formal business, and after that the Therapy Section will meet under the chairmanship of Dr. Robert McWhirter; at 2.30 p.m. the Diagnosis Section will meet at the Western Infirmary, with Dr. Peter Kerley in the chair; and at 5 p.m. the National Health Service Bill is to be discussed by Fellows in general session. On the morning of the second day both sections will meet jointly at the Natural Philosophy Department of Glasgow University for a symposium on applications to biological and medical research of modern developments in nuclear physics.

With the agreement of the Colonial Office, the National Association for Prevention of Tuberculosis has formed a special committee to give advice on x-ray methods and apparatus used throughout the British Colonies. The members of the committee are Dr. R. R. Trail (chairman), Dr. J. M. Cruickshank (representing the Colonial Office), Mr. J. T. Ferrier, Dr. A. Stephen Hall, Dr. P. Kerley, and Dr. Harley Williams (secretary).

A silver cigarette-box and a cheque were presented to Major-Gen. R. C. Munday, C.B., retiring chairman of the Plymouth Medical Recruiting Board, at a luncheon given by him to fellow-members of the Board in the Grand Hotel, Plymouth, on May 25. Gen. Munday said it was his wish to give the cheque to the Royal Medical Benevolent Fund.

Penicillin can be supplied only on a prescription from a registered doctor or dentist. The Pharmaceutical Society points out that the retail prices fixed by the Ministry of Supply are for dried penicillin powder and not for the various preparations in which it will be used by the public.

Dr. C. H. St. John has been appointed a member of the Legislative Council of the Island of Barbados, and Mr. Aubrey Scott Gillett, F.R.C.S., has been appointed a member of the Executive Council of the Island of St. Lucia.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* an increasing incidence was reported for measles 629, acute pneumonia 96, and dysentery 80; the only fall of any size was whooping-cough 231.

The largest variation in the local trends of scarlet fever was an increase in London of 26. The only appreciable change in the returns of diphtheria was an increase of 12 in Yorkshire West Riding. The fall in whooping-cough was common to all regions except London and the south-eastern and northern counties, which showed little change.

Measles appeared in Anglesey during the week, and 101 cases were notified; the remainder of the increase in measles was accounted for by the counties where the disease was already prevalent. The largest rises were London 198, Essex 115, Surrey 67, Lancashire 57, Yorkshire West Riding 51.

The rise in dysentery resulted from increases in existing outbreaks. The largest returns were Lancashire 35, London 16, Middlesex 16, Oxford 12, Essex 12, Warwickshire 12, Devonshire 11, Surrey 9.

In *Scotland* the chief feature of the returns was a fall of 31 in the notifications of diphtheria, other declines in incidence being whooping-cough 43, dysentery 14, scarlet fever 11. Increases were reported for measles 49, and acute primary pneumonia 21.

In *Eire* a fall occurred in diphtheria 19, and measles 40. There were 22 cases of diarrhoea and enteritis.

In *Northern Ireland* the only change of note in the returns was a fall of 7 in diphtheria.

Week Ending June 1

The notifications of infectious diseases in *England and Wales* during the week included: scarlet fever 1,070, whooping-cough 2,059, diphtheria 304, measles 3,931, acute pneumonia 596, cerebrospinal fever 54, acute poliomyelitis 9, dysentery 163, smallpox 2, typhoid 5.

Corrigendum

In the figures for the week ending May 18 the increase of 20 cases of diphtheria in *Eire* has since been corrected to an increase of 14.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 21

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) *Eire*. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in *Eire*. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

ANY QUESTIONS?

Metabolism of the Nervous System

Q.—Please give an account of the metabolism of the nervous system. What is the influence of the central nervous system on the general metabolism?

A.—The gaseous metabolism of the brain has been studied in animals, including man, by comparing the composition of arterial and venous (internal jugular) blood and measuring the cerebral blood flow. Studies of isolated brain tissues (sliced or minced) have also been made. It seems likely, because the L.Q. is usually 1, that the brain gets its energy mainly by the oxidation of carbohydrate. Both glucose and lactic acid are taken up from the cerebral blood and apparently oxidized, since there is no evidence of glycogen storage. The reserves of carbohydrate are low. The mental confusion, delirium, and possibly convulsions which develop in animals in "insulin shock," or after hepatectomy, are probably due to hypoglycaemia, and the relief of the condition by the injection of glucose suggests its importance in the normal functioning of the brain. Vitamin B₁ probably acts as a coenzyme in facilitating the oxidation of glucose; this may explain the nervous symptoms which accompany B₁ deficiency. The scope of the question is, however, so large that no adequate answer can be given here and the questioner is referred to Page, *The Chemistry of the Brain* (1937), and Holmes, *The Metabolism of Living Tissue* (1937).

Diphtheria in the Immunized

Q.—I saw recently a fatal case of diphtheria in a girl of 6 who had been immunized about two years ago. Would it not be desirable for county authorities to record the number of diphtheria cases that have actually been immunized?

A.—The occurrence of diphtheria in inoculated persons is now generally recognized and accepted; the incidence of infection among the inoculated has been estimated from the annual returns of local authorities to be in a ratio of 1:3½ of the uninoculated. There are several possible explanations for the appearance of diphtheria in inoculated persons. (1) Diphtheria toxoid immunizes against the toxin of the organism and not against the organism itself, so that strains of the diphtheria bacillus that have a certain "invasive" power, as seems to be the case with the *gravis* and *intermedius* types, may be able to establish a local throat infection with membrane formation (diphtheritic tonsillitis) but without toxæmia. (2) The antitoxic immunity which develops after a child has received a course of diphtheria prophylactic begins to wane after some months, and in two or three years may have fallen to a very low level. If at this stage the child is attacked by the diphtheria bacillus the antitoxic response of the tissues may not be mobilized quickly enough to prevent the formation of enough toxin to do some damage. As a rule such infections are not severe and a fatal issue is rare. Thus, the mortality among immunized children has been estimated at a ratio of 1:25 of unimmunized children. (3) The immunizing agent may be a poor one, as happened in the early years of the war with a particular batch of A.P.T., but the chance of this happening in this country to-day is minimal.

To reduce the risk of infection among children who have been immunized in infancy and who may have lost a good deal of

their antitoxic immunity in the pre-school years, a boosting dose of 0.2 ml. A.P.T. should be given when the child goes to school, and this dose may, if thought necessary, be repeated five years later. In this way antitoxic immunity is maintained at a reasonably high level and the chances of fatal infection are very small.

Proper recording of the state of immunization of the child community is certainly needed, and has been strongly advocated by the Ministry of Health (see *Monthly Bulletin*, September, 1944, p. 142). Provision has now been made for improving the returns made by medical officers of health so that the incidence of diphtheria in immunized and unimmunized children of different age groups can be compared, and more precise data will thus be obtainable on any deaths from diphtheria in immunized children.

Glass and Ultra-violet Light

Q.—Does glass specially made to permit the passage of ultra-violet light lose this property with age? If so, what is the rate of loss?

A.—Such special glasses do lose their transparency for ultra-violet light to some extent with age—i.e., duration of exposure to ultra-violet radiation. The rate of loss, and the final, stable transmissivity, differ for different glasses. When used in windows the ageing of the glass is usually complete within twelve months, and the transmission factor may be reduced appreciably—in some specimens by as much as 20%. The loss is due to the presence of impurities in the glass, and can be made small by careful control of materials in manufacture. A high degree of stability is claimed for some of these transparent glasses.

Wuchereria bancrofti

Q.—Is there any specific treatment for filariasis due to *Wuchereria bancrofti*?

A.—There is no drug therapy which can be relied upon to eradicate *Wuchereria bancrofti*, but several compounds, particularly the organic antimonials, may bring about a temporary disappearance of the microfilariae, and on occasion may even appear to succeed in eradicating the infection. Thus of 30 patients treated with 0.3 g. of neostibosan on alternate days for from five to seven weeks, 13 were free from circulating microfilariae after twelve months. Little or no change occurred in the microfilarial levels during, or immediately after, treatment, and it is suggested that the slow loss of the microfilariae was due to the action of the drug on the adult worm. Progressively increasing doses of filarial antigen may relieve patients of symptoms presumably due to sensitization to products of the parasites, but here again treatment is uncertain in its effects.

Subarachnoid Haemorrhage

Q.—A man of 50, previously healthy and with a normal blood pressure, did four years' service in the Middle East. He was subjected to considerable physical and mental strain for some months before he collapsed with a subarachnoid haemorrhage. He is now well again, apart from some loss of energy and drive. (1) What is the prognosis? (2) What precautions should be advised to avoid a recurrence? (3) Is it true to say that the subarachnoid rupture of a presumably congenital aneurysm is quite unrelated to earlier physical and mental strain? (4) Is 50 the usual age for such cerebral accidents?

A.—(1) The prognosis must be guarded as there is always a prospect of recurrence. In Magee's series of 150 cases, 50 patients had a recurrence of bleeding; and as 52 of the total original series died, the 50 recurrent cases are to be related to the surviving 98 (*Lancet*, 1943, 2, 497).

(2) It is difficult to formulate dogmatic rules to prevent such a catastrophe, especially as in most cases of spontaneous bleeding no precipitating, or even provocative, features can as a rule be traced. Nevertheless, common sense enjoins that the patient should be warned against lifting heavy weights, or cranking his car, or making any sudden and strenuous physical exertion. Over-tiredness from sustained and excessive physical and mental work should also be avoided so far as possible.

(3) Earlier physical and mental strain may well be claimed as an aetiological factor provided that there is a reasonably

such a case. A small boy, listening to a major and a colonel both of whom stammered, and being filled with admiration for them, likewise began to stammer, and continued to do so till he was about 30. He then decided to give it up and spoke normally. Unfortunately, most cases of stammering are much too deeply involved to be cured so easily. There seems little doubt that, in the case mentioned, with the departure of his father the identification was broken, and, the suggestibility coming to an end, the patient spoke normally.

Spontaneous Combustion of Quilts

Q.—A patient put her baby out in the sun in his perambulator. For no apparent reason the baby's quilt, made of artificial silk lined with splint wool (upholsterer's wadding), burst into flames. Are such quilts likely to undergo spontaneous ignition in sunshine?

A.—In the writer's opinion this accident is to be attributed solely to the wadding lining of the quilt, which has become contaminated with oil—probably in a high local concentration. The conditions of warmth have led to rapid oxidation of the oil with an increase in temperature, leading ultimately to combustion. This phenomenon is well known with unscoured oils. If subsequently oil-contaminated, fibre when the conditions are favourable. The writer came across a similar instance in an aeroplane seat about 1916. In that case local concentrations of kapok-seed oil in the kapok stuffing were shown to have caused spontaneous combustion. A rapid and efficient method of determining the liability of oils on fibre to develop heat spontaneously is provided by the Mackey cloth oil tester, which is obtainable as a standard apparatus.

Red Hair and Bleeding

Q.—Do patients with red hair show an undue tendency to bleed during surgical operations?

A.—In thirty-five years of surgical experience the writer has never noted that patients with red hair have shown any undue tendency to bleed during a surgical operation, nor has he ever heard anyone put forward that suggestion. However, the matter could easily be put to the test by estimating the coagulation time of a series of red-haired patients and comparing with control series.

INCOME TAX

Car Expenses

J.P. bought a car in 1939 for £148 and has been allowed depreciation on it every year; he sold the car on Dec. 31, 1945, for £210 and then bought a new car for £400. The practice accounts are made up to April 4. What should he claim "for the year ending April 4, 1946"?

A. The depreciation and similar allowances are due for the financial year, not as a deduction from the profits of the year of account. The relevant question is, therefore, what allowances should be claimed for the financial year ending April 5, 1947. No allowance is due in respect of the old car. As regards the new car, the following allowances should be claimed: (a) an "initial" allowance of 20% of £400 = £80, and (b) a "depreciation" allowance of 25% of £400 = £100.

Sale of Practice and Cars

M. M. asks two questions: (a) He sold his practice and two cars on Jan. 1, 1946. Is he liable for "balancing charges" on the excess of the amount obtained for the cars over their written-down value? (b) He bought the share of a deceased partner in 1942. Does that raise his limit in respect of insurance premiums (Sec. 9 of the Finance Act, 1941) by the income his late partner derived from the practice in 1938-9?

A. (a) M. M. is not liable for balancing charges, and his partner can claim allowances based on the amounts at which the cars changed hands. (b) No. Under the provision referred to the limit of income is "the total income of the year of assessment or . . . for the year 1938-9, whichever is higher." Life insurance relief is a personal matter, and the 1938-9 income is M. M.'s income, unaffected by subsequent events.

Remittances from Colonial Earnings

N. C. M. has bought a house in the United Kingdom and consequently ranks as a "British resident."

A. He will be liable as a British resident for the whole of the present financial year—i.e., the year to April 5, 1947. Remittances to this country will not be liable to income tax if the period of

Colonial employment is three years or more and he is absent for the whole of the financial year concerned. Remittances from capital are not liable as income, but the discrimination involves difficult questions. If, for instance, there is foreign current income available for the remittance and the amount is remitted to meet current (i.e., non-capital) expenditure here, the claim that the remittance was one of capital might fail.

Claim for Arrears of Tax

D. C. was employed during 1940-2 as M.O.H. to four authorities in a combined appointment; it was understood that tax would be deducted by the authorities from their payments for salary but not from their payments for expenses. He has now been informed by the local tax office that the deductions made for the year 1940-1 were insufficient and that he is liable to account for the balance of £125.

A. It seems that something must have gone very wrong with the collection arrangements to produce so unfortunate a result, and D. C. is, we think, entitled to a much fuller explanation than he has so far received. But if the full amount of tax due has been assessed—in which case D. C. will presumably have received a formal notice—but part remains uncollected, it is still a legal liability, and we fear that D. C. cannot avoid it even if he is in a position to show that either the tax office or the authorities, or both, were to blame for failing to obtain the tax at the proper time.

LETTERS, NOTES, ETC.

Peritoneal Gloves in Primitive Surgery

Gp. Capt. G. STRUAN MARSHALL writes from Edinburgh: Dr. A. R. Eates mentions (May 4, p. 709) the use by Arabs of ants as Michel clips. There will be found, in a book written about twenty years ago—*Secrets de la Mer Rouge* by Henri de Monfreid—and published, I think, in Paris, a fairly detailed account by an intelligent layman of an operation in the Sinai Desert that should still further amuse Dr. Eates's virtuosi. De Monfreid seems to have been a pearl fisher in the Red Sea, intermittently dodging those who would interfere with his apparently nefarious trade. He writes of an occasion when he had landed and gone up country; a tribesman was brought in, suffering from a deep spear wound of the belly. After some delay a native "doctor" appeared and gave the injured man something to suck that seemed to blunt his sensation. Then he examined the wound, and got an acolyte to hold it open. He extended the wound with a blade dipped in very hot melted butter, and exposed the stomach, which had been penetrated by the wounding spear and was gaping. He now had a goat killed and its belly opened; he extracted the omentum and draped it over his hands, and with these natural gloves handled the stomach. Holding the cut edges of the stomach wound together, he took a large ant from a vessel, held it just behind the head, and brought it to the approximated edges of the wound, when the ant's mandibles closed firmly on them. At this moment he brought his nails together, nipping off the ant's head, which remained clamped to the cut edges, holding them together securely. Four points of interest emerge: the anaesthetic, in a country where alcohol is forbidden; the keratinous Michel clips, or rather visceral clips, which would presumably not be dissolved by the peritoneal fluid for a very long time, if at all; the surgical gloves of the only ideal material imaginable, which, being themselves peritoneal, would not injure the peritoneum in the slightest; and the sterilization by moist heat, probably greater than that of boiling water, in a medium that would lubricate the knife. I write from a tenuous memory, and may have got minor details slightly wrong, but I am sure of the major ones, and can only wonder at so modern a development of surgical technique in a country where communication is difficult and scanty. *Ex Africa semper aliquid novi*—well, not quite Africa but near enough.

A Close Shave

Dr. FRANK CROSSIE (Ealing) writes: The communication from Dr. L. ERASMUS ELLIS (May 4, p. 710) tempts me to offer to my fellow "tender-skins" the gleanings from upwards of half a century's trial and error. The points in order of importance are: (1) Cold water for both lathering and washing off. (2) A sharp open razor and a pannikin of really hot water into which the blade should be dipped frequently throughout the operation. (3) Perform the operation after the tub, preferably in the shirt and trousers stage. (4) The use overnight of an ointment containing a few grains each of acid. salicyl. and pulv. sulph. praecip. ad 1 oz. (28 ml.) eucerin base. (5) Liq. hamamelidis (B.W.) is unrivalled for post-operative purposes. (6) A base of soap from a stick on the face plus an overlay of cream on the brush; to preserve the life of the latter (a consideration these days) don't remove the remains of the old soap till just before re-use.

Proctalgia

Col. N. J. C. RUTHERFORD (Farnham) writes: This correspondence has interested me as I started the subject in the *Journal* in 1929 by asking for suggestions for treatment. Quite a few doctors answered, but "I evermore came out by that same door where in I went." I have had the complaint since the 1914-18 war. The attacks come on at any time, day or night, and the pain can be severe enough to make one halt if walking or sit down if in the house. The only cure I know is heat; at night sit on a hot-water bottle or electric pad; during the day, when or where available, crouch down, semi-sitting, over an electric or gas fire. Another member of my family, a lady, has also had the complaint for over twenty years. In future I shall try the gastro-colic reflex advised by Prof. F. C. Pybus. Threadworms and slight eczema were suggested to me as causes, but did not fit in my case. As I get older I find the attacks come at longer intervals; perhaps I may grow out of them in my octogenarian years!

Dr. N. H. STEIN (Edinburgh) writes: I suggest that the symptoms described under the headings of proctalga, etc., are due to a prolapse of the lower part of the pelvic colon into the rectum, occurring intermittently and leading to a congested state of the mucous membrane. Incomplete return leads to a small faecal mass being caught in the inflamed area, increasing spasm, and acute pain. The initial cause of the prolapse may be some congenital weakness in this part of the gut, the presence of a polyp, or obstruction by kinking due to the adhesion of neighbouring structures. An adherent appendix would tend to produce this. In many cases, if not in all, it is simply the persistence into later life of the condition of prolapse recognized in young children. In an extreme case, in which this prolapse was easily demonstrable, there was a history of this. I shall be glad to give further details to those interested.

Nocturnal Erections

Dr. WRIGHT LAMBERT (Keighley) writes: Oestrogenic therapy was suggested to me by Mr. H. Hamilton Stewart, of Bradford, for the treatment of troublesome and frequent nocturnal erections in a patient, 58 years of age, on whom Mr. Stewart had performed prostatectomy (5 oz. (140 ml.) of residual urine) by the transurethral route, and whose priapism, without any apparent sexual libido, was not cured by the operation. Stilboestrol, 5 mg. daily, keeps him entirely free from the condition, but he relapses almost as soon as he stops treatment. Mr. Stewart recently suggested that dienoestrol 0.3 mg. would be equally effective and be less liable to produce untoward side-effects. This patient got no relief from phenobarbitone gr. 1/2 (32 mg.) at bedtime. Whilst oestrogenic therapy for this condition would seem to be based on sound physiology, I cannot see why the androgen testosterone (June 1, p. 864) should be successful. Mr. Hamilton Bailey in the *Medical Annual* (1945, p. 232) mentions Cave's operation, incision of the corpora cavernosa, evacuation of blood clot, and packing with gauze, as having been completely successful in one case.

Nasal Cleanliness

Dr. PERCY TATCHELL (London, S.W.5) writes: The late Sir Buckston Browne was emphatic that by taking snuff he avoided colds in the head. Snuff-taking was a common practice in the last century, with the object largely of preventing infection. This presumably it did by creating a profuse discharge, which washed out the nose. There is no need, however, to take snuff to attain that end; it is easily done manually when washing the face. One may say: "Why not use a spray, is that not better?" People will not be bothered; they use the spray once or twice, and get tired of the paraphernalia and the mess. Besides, a spray by-passes the glutinous mucus found in the wings of the nose, a first-class nidus for bacterial growth. It is only a matter of a few moments to do it with the soapy fingers, and experience will show that soap does not sting appreciably unless sucked up to the turbinate bones. In this region matters can be left to one's natural defences. I believe, by the adoption of this simple routine, the risk of infected colds, all the fevers of adolescence, and such mysterious air-borne ailments as influenza, and the appalling catastrophe of infantile paralysis, can be greatly diminished.

Remedies for Herpes Zoster

Dr. W. H. MARSHALL (East Grinstead) writes: The experience of general practitioners is often different from that of consultants. In my experience pitressin 1 ml. (0.5 ml. for the aged) gives striking relief to almost all cases of herpes zoster if given in the early stage before the rash has finished coming out; the earlier crops lose their pain, and the later ones appear as an erythema and then vanish with little or no vesicle formation. Relief is obtained within five minutes, or at the most half an hour, or not at all.

Dr. HUGH DICKIE (Morpeth) writes: May I give a brief account of an accidental discovery of mine which appears to be a complete

cure for herpes zoster? While acting as M.O. to Offlag IVc, Germany I was desperate to find some relief for a young officer with a very severe attack of dermatitis herpetiformis. I had tried everything in my short range without effect, and, more in an attempt to raise his general tone, I gave him 4 ml. of a liver extract intramuscularly. The next day he was well! No new spots and the pain had gone from the old ones. Five months later he had another attack; same treatment immediately and the whole thing aborted. We then tried this "treatment" on a French lieutenant with a very severe intercostal herpes. This man had some experience of shingles—his wife and mother had both been very ill with it some years previously. On the day after the injection of liver extract I was overwhelmed with a profusion of Gallic thanks—all the pain had gone, no new eruptions, and within a week all the original papules had healed. Next came two British soldiers, with equally startling results. I have now "treated" 7 civilians at home in this way, age range from 26 to 81 years, with herpes ranging from supra-orbital to twelfth dorsal. All cases were treated within the first forty-eight hours of the appearance of the rash, and all responded overnight. Admittedly the number of cases, 10 in all, is slight, but the results are so striking that I feel some publicity should be given to them, and perhaps someone with a more scientific outlook may find the reason.

Contramine for Herpes

Dr. E. S. HAWKES (Budleigh Salterton) writes: May I correct your reply to the first of "Any Questions?" (May 25, p. 822). If you refer to a Medical Memorandum (Sept. 25, 1943, p. 391) you will find my article which gives the inquirer the information he seeks. It will be noted that it does not apply to a few isolated cases, but a series of 15. The remedy is effective only in early cases. It is also most effective in early chicken-pox.

"Cord Round the Neck"

Dr. V. P. ROBINSON (Norfolk) writes: It may be of interest to report that I recently confined a girl aged 16; the cord was round the neck loosely and was easily slipped over, but the child was born dead. A tight knot was found in the cord, which was 39 inches (1 m.) long. Movements had ceased for about two days.

Injections on Board

Mr. C. D. L. STEWART-FORSHAW (Roche Products, Ltd.) writes: Surg. W. S. Parker in *Referring* (May 18, p. 775) to a specially developed "tubonic" ampoule appears to be unaware of the remarkably efficient unit called "tubonic" ampoule syringe (tube unique) originally introduced by my firm some years before the war. This unit is essentially for such emergencies. During the war it was part of the equipment in the Merchant Navy in all lifeboats, and it was also employed by a number of special units of the Services. I am proud to say that it was responsible for saving a number of lives.

Medical Journals for Hungary

Mr. EDWARD FULLER, Editor of the *World's Children*, writes from 20, Gordon Square, London, W.C.1: Some little time ago you very kindly gave publicity to a letter from me, passing on a request from the Save the Children Fund's administrator in Hungary, for British medical periodicals, to help bring Hungarian practitioners' knowledge up to date. A number of your readers generously responded—and some pass on their own copies regularly after use. These—and any prospective new donors—may like to know that I have to-day had a letter from the Hungarian correspondent, who says: "Please thank for me all who are concerned in sending the medical papers. They are of infinite value. They go round among the doctors and will finish their career in the library of the central clinic."

Medical Golf

By courtesy of the Stockport Golf Club the annual competition of the Manchester and District Medical Golfers' Association will be resumed on the course at Torkington on Wednesday, June 26. The Challenge Cup will be competed for by medal play under handicap; the winner will hold the cup for one year, and the captain (Mr. R. L. Newell) will give a second prize. The Walter Gold Medal will be held for one year by the member returning the best gross score, and the Walter Silver Medal by the member returning the best gross score from among those with handicaps of ten and upwards. Prizes will be provided for the winners in lieu of replicas. All correspondence should be addressed to the hon. secretaries, Manchester and District Medical Golfers' Association, c/o British Medical Bureau, 33, Cross Street, Manchester, 2.

Correction

The figure 0.4 in line seven under the subheading "Results" in the article by Dr. R. C. Browne on "Amphetamine and Caffeine Citrate in Anoxaemia" in last week's issue (p. 871) should read 1.2.

LONDON SATURDAY JUNE 22 1946

SOME ASPECTS OF CHEMISTRY RELATED TO MEDICINE*

BY

Sir ROBERT ROBINSON, D.Sc., P.R.S.

It is a great privilege to be the first to have the opportunity to congratulate the Board and all those who labour within these walls on the Bicentenary of the Middlesex Hospital. The Foundation took place shortly after the death of Boerhaave, of Leyden, the greatest of eighteenth-century teachers, and also near the date of the birth of Lavoisier. Thus the entire development of scientific medicine and modern chemistry occurred during the period now celebrated. I speak to you as a chemist, and my acquaintance with medicine is superficial—rather like a Nature-lover's knowledge of scientific botany and zoology. As a concession to my diffidence I trust I may be allowed to alter the title of my address from "Chemistry and Medicine" to "Some Aspects of Chemistry Related to Medicine."

There are few human activities that have no relation to medicine, and it is equally true that all branches of medicine are already connected, or are destined to be connected, with chemistry. It would be preaching to the converted to develop that theme as propaganda, because the clock will not be set back, and the fundamental nature, for medicine, of the science of the transformation of matter is already fully recognized. Chemistry is of service to medicine in very many directions, of which I will mention only the more important. There are the alloys, plastics, and other materials used to improve the technique of medical and surgical practice. Many of these are incidental to more general developments, but others have involved specific research. In the field of preventive medicine the purification of water, for example by chlorination, should not be overlooked as an application of chemistry, whilst the production of new insecticides and insect repellants is making an increasingly important contribution to hygiene. The huge subject of nutrition, involving vitamins, essential amino-acids, minor elements, and the balance of diet, is obviously a meeting-ground of chemists and physiologists.

Then, more directly, we have the general and local anaesthetics, the analgesics and hypnotics; also the substances which promote or inhibit various bodily functions—an omnibus definition which could embrace the natural and synthetic hormones, insulin and the liver factors, thiouracil, etc., and also groups such as the laxatives, diuretics, and so on. There is no danger of forgetting the chemotherapeutic agents, which we may class together irrespective of the mechanism of their action. Finally, we have the subject of toxicology, the use of chemical analysis and biochemical control in diagnosis, the blood groups, and immunology.

That list is by no means complete, and I shall make no attempt to cope with it.

As an organic chemist I propose to make some general remarks and to mention a few special themes, chosen because I happen to have been interested in them, and certainly not because of their intrinsic significance in the general picture. And first I want to emphasize that organic chemistry must still be developed for its own sake; it is very imperfect, and not yet a reliable handmaiden for other sciences. It is perfectly true that great success has attended the isolation of substances of physiological importance and that many of these have been ingeniously synthesized. As a result many medical scientists

have come to the conclusion that our technique is adequate for almost any task. But the truth is that we can quickly cover only such ground as the advance of knowledge makes accessible.

Our position is similar to that of the metaphysicians, who always manage to catch up to the wave of scientific progress, but never take a step in front of it. Or, to take a closer analogy, chemistry is to medicine as mathematics is to physics. The physicist, however, has usually enough mathematical equipment to make it possible for him to appreciate the limitations of the power of mathematicians to solve his problems. He knows that an increase of these powers will inevitably raise his own potential, and he therefore encourages the pure mathematician even in work that seems devoid of any possible application.

In the case of organic chemistry applied to biological research it is easy to see the direct results of relatively recent improvements in laboratory methods such as micro-analysis, chromatography, molecular distillation, use of tracer elements, x-ray analysis of crystals, and ultra-violet and infra-red spectrography. It is well understood that this and that advance in physiology, or other medical science, would have been impossible without these facilities, or at least would have been greatly delayed. But what is perhaps not so widely appreciated is the debt owed to pioneers of structural and synthetic chemistry, to the discoverers of general reactions, and to those who have disclosed the mechanism of reactions and the relations between properties and molecular constitution.

The system of organic chemistry is a wonderful achievement, but the noble edifice that has been reared is still unfinished. The reason for stressing the point is that there may be some danger of too great a diversion of scientific man-power into *ad hoc* work, even if that consists of the wholly admirable studies of biological problems. It is perfectly true that some of these will be found beyond our present capacity to solve and that such research will disclose the existence of gaps in knowledge and may lead to the exploration of a rich territory.

In the past the study of natural products has indeed afforded that kind of stimulus. Outstanding examples are the carbohydrates, the terpenes, the alkaloids, the steroids, and the vegetable and animal colouring matters. These substances were easily accessible in quantity, and they were examined mainly for their purely chemical interest. If I may be pardoned a personal reference, I have been asked why I am still interested in the study of strychnine. Except as a tonic and vermin-killer it is of no particular use, and its biological significance as a waste product of the economy of the plant is not apparent. The answer is that we are interested in the behaviour of a unique molecule which contains no fewer than seven interlocked rings, and that we have faith that the investigation will add stones to that edifice I have already mentioned, on which others will later be placed. And whether that is so or not, the challenges of Nature have to be accepted. It is not for us to presume to assess the importance of new knowledge to future generations.

When Wieland and Windaus attacked the steroids it was from this point of view alone, though we must admit that the steroid hormones were a kind of bonus not likely to be often bestowed in such generous measure.

* Address at Bicentenary Celebrations of the Middlesex Hospital, May 20, 1946.

Penicillin Synthesis

The chemistry of penicillin gives a good example of quick success in one direction by the use of established methods and of failure in another, due to the fact that a certain field of synthesis has not yet been cultivated. After the preparation of penicillin concentrates, it was a matter of routine to find the conditions of stability of the antibiotic and, though it proved a difficult task, to obtain the pure crystalline sodium salt.

The determination of molecular structure was also far from easy, but it followed normal lines of procedure. A final doubtful point was cleared up by x-ray analysis of the crystals. The substance is relatively simple. Everything seemed plain sailing for the synthesis, and yet very strong American and British teams have been unable to achieve it in a practicable manner. It is very probable that penicillin has actually been synthesized, but the yield is only about 0.1% of the theoretical, and the method has therefore no practical importance as it stands. The explanation is that we are faced with a new kind of difficulty presented by the great instability of the molecule, combined with a lack of methods suited for the construction of the characteristic β -lactam unit, under the conditions imposed by the properties of the substance. All the known methods are too brutal for that delicate system. So we have to find some new method, and that sequence of operations is not what we had hoped for, and has indeed seldom been necessary for the synthesis of natural products of comparable complexity. Somewhat analogous were the syntheses of indigo by Baeyer, Heumann, and Sandmeyer, because there was no precedent for the reactions that were eventually discovered after many years of intensive work. Ziegler's device for overcoming the reluctance with which large rings are formed was entirely novel, and something similar to it may well apply to the case of penicillin.

Our medical friends, who have seen a whole series of vitamins and hormones synthesized very soon after their characterization and structural analysis, are keenly disappointed in us. Dr. Vannevar Bush remarked, "They tell me that it is only a question of removing a molecule of water." Alas, that is all it is!

While on this topic I will add that though total chemical synthesis, or rather synthetical manufacture, is not in sight, biosynthesis, by appropriate feeding of the mould, has given us new penicillins. Moreover, one of the penicillins has been chemically modified, with the production of substances of increased activity. Thus we already have a range of penicillins which, as in the case of the sulphonamides, will doubtless be differentiated in regard to their suitability for the treatment of infections. It follows that one of the advantages anticipated from chemical synthesis has been partly secured in a different way. I do not want you to conclude that the prognosis for synthesis is unfavourable. On the contrary, the problem is well defined, and will be solved—when we have had time to learn some more organic chemistry.

A Gap in our Knowledge: Proteins

The most obvious gap in our exact knowledge of substances of biological importance is in relation to the proteins. Their molecular complexity, and variety in complexity, continue to defeat us, but, nevertheless, great progress has been made and the outlook is promising. At Harvard University Medical School, Prof. Cohn and his colleagues have built up a most impressive laboratory, devoted to the application of physico-chemical principles and methods to the separation and study of proteins. There is room in this country for a similar "Institute of Protein Chemistry." There is no more important subject, and none that offers greater rewards to the investigator.

It is a matter for congratulation that Prof. A. C. Chibnall has brought his great experimental skill and critical faculty to bear on the analysis of proteins and the interpretation of the results; similarly, that Prof. A. R. Todd is so well on the way to the synthesis of sections of the nucleo-protein molecule and, incidentally, of the coenzymes. It is also good to know that the urgency of the work is recognized here and that Prof. E. C. Dodds has embarked on a study of physiologically active proteins. By contrast with these I am reminded of the useful "dead" proteins—wool, silk, leather, and even pea-nut

protein. Much valuable work has already been carried out by the respective research associations—for example, Dr. Jordan Lloyd's leather team—and all that will come into the mill.

The indications are that the probing of the protein molecule will before long reveal the mode of organization of the units, but that is only the first step to a real understanding of their role in Nature. We are almost compelled to believe that the nucleo-proteins are keeping one of the secrets of life itself, and it is hard to resist speculations that connect the four great and peculiar branches of their molecules with a mechanism of biosynthesis of particular importance. To regard them as a kind of template, on which other molecules are moulded, is doubtless a crude conception, but the proliferation of viruses shows that in a suitable environment macro-proteins can reproduce themselves.

We know that the viruses and bacteriophages cannot be generalized and that they vary greatly in size, by a factor of at least 1,000, and in organization. It must also be admitted that the host may make an essential contribution to the reproductive process—for example, by the provision of raw material such as amino-acids. Nevertheless reproduction does occur, and some day we shall know how. That knowledge will be of the greatest consequence to the human race, and all the resources of physical and biological science should be brought to bear on the quest. The discovery of the intimate mechanisms of biosynthesis of proteins would clearly have repercussions in fields such as heredity and ageing, and it might show the way to the conquest of cancer and the viruses.

The study of living things necessarily starts with the family, then proceeds to the individual organism, then to its parts—morphology before physiology; it is a development from the outside inward. The physical sciences often adopt the same method; but the system of organic chemistry, like mathematics, proceeds from the simple to the more complex. It seems that the biologist and the chemist, using these different methods of approach, are nearing one another at the level of the proteins and viruses. Godspeed to their meeting.

I would now like to refer to a few matters of detail. As I have already said, the selection I have made is somewhat arbitrary and reflects my own recent interests.

Configuration of Antibiotics

The hydrolysis of penicillin—of all the penicillins so far as is known—affords a bis-homologue of cysteine called penicillamine. This is not the dimethyl derivative of natural *l*-cysteine, but of the optical antipode, *d*-cysteine. The configurations of the amino-acid units of proteins are related; they are all male screws or perhaps all female; we can't tell which. Thus penicillamine belongs to the "unnatural" family of amino-acids. Similarly gliotoxin is degraded to unnatural *d*-alanine, and the peptide group of antibiotics such as gramicidin seem also to be built up largely from unnatural amino-acids. It has just been reported that streptomycin can be degraded to *l*-glucosamine, whereas the natural glucosamine is the *d* form. These coincidences are significant.

Dr. J. W. Cornforth has suggested that the common factor may well be that the antibiotics are protected from destruction in the body by their antipodal configuration. This seems a reasonable view, and it leads to the conclusion that whereas optical activity is certainly not always an essential feature of a chemotherapeutic agent, yet, when the possibility exists, the *d* and *l* forms should always be tested separately.

Gause states that the *d*- and *l*-mepacrine are equally effective against malaria, but that the *d* variety is only half as toxic as the *l* variety. Hammick and Chambers, using the racemic compound, found that the *d* form is metabolized in the body, and that the drug excreted in human urine consists entirely of the *l* isomer. The collation of these results does not spring to the eye, but, as in other matters, anything is more welcome than indifference.

Toxic Fatty Acids

Dr. N. Polgar has been studying the fatty acids of tubercle bacilli, first examined by Anderson. They are of interest because of their toxicity and power to produce lesions in experimental animals. The saturated phthioic acid, $C_{24}H_{48}O_2$, is typical of a whole range of these constituents that can be isolated from the bacillary bodies. The available evidence

indicates that it is 3:13:19-trimethyltricosanoic acid—that is, it is a straight-chain C_{22} acid with three methyl notches. A synthetic acid of this structure which has been obtained is probably a stereo-isomeride of phthioic acid. This, and a related unsaturated acid, are markedly toxic, and examination of near relatives shows that the property is highly constitutive. Polgar suggests that the methyl groups may facilitate dehydrogenation in their vicinity and that the products may antagonize some essential unsaturated fatty acid. It is too early to discuss this tentative hypothesis, but we no longer regard this investigation from the point of view of a direct attack on the bacilli. The objective is now to find a means of alleviating the symptoms of the disease and thus perhaps to give it a more favourable course.

Action of Carcinogenic Agents

The mechanism of the action of carcinogenic agents and the relation of carcinogenicity to constitution have been the subject of much research and discussion, but no generalization has emerged. This is certainly partly due to the fact that the biological experimentation has not been standardized and to the doubtful nature of many of the findings. Dr I. Berenblum and I have surveyed the results and think that the weight of evidence indicates the possibility of reaction at an activated phenanthrene-type bridge in the great majority of cases, but there are apparent exceptions, and more than one mechanism may be involved. We do not intend to advance even a provisional hypothesis until more experimental evidence has been gathered.

One method of attack is to test substances derived from known carcinogens by replacement of a benzene ring by the isosteric thiophene nucleus. It has been found that such substances may be powerful carcinogens. In the case of 9-10-dimethyl-1:2-benzanthracene there are three benzene nuclei that might be so replaced. In two of the cases, that has been already carried out by Fieser, and the products are reported to be carcinogenic. B. Tilak has now made the third isomeride at Oxford. In this the phenanthrene bridge is replaced by sulphur, and the substance is not carcinogenic by subcutaneous injection. It is weakly carcinogenic in the painting technique, but the tumours show a tendency to regress. Many other examples must be studied, and the observations of Dodds, Lawson, and Williams that α -ethyl- β -sec-butylstilbene is carcinogenic can be brought into line with the phenanthrene-bridge idea only by assuming dehydrogenation of the agent *in vivo*.

There are many tantalizing indications of the possibility of a chemotherapy of cancer which is, however, never likely to prove so simple a process as the control of an infection by a sulphonamide or penicillin.

A considerable number of substances have been observed by Haddow and others to cause retrogression of tumours in experimental animals, but, so far as I am aware, none has found practical application. A different approach is mentioned by Prof. Gye in his recent report of the Imperial Cancer Research Fund. A delay in the appearance of mammary cancer in mice can be brought about by thiourea, which blocks thyroid activity and so lowers the basal metabolic rate.

That is, by way of digression, another fascinating story of the interaction of chemistry and medicine. It includes Harington's work on thyroxine, culminating in its synthesis, and the demonstration of its biosynthesis from the tyrosine bound in proteins; as well as the use of thiourea, then thiouracil or its alkyl derivatives, in cases of Graves's disease.

But the most dramatic indication that certain types of carcinoma may be amenable to chemical treatment arises directly from the work of Prof. E. C. Dodds, here at the Middlesex Hospital. It would certainly be carrying coals to Newcastle to describe the stages by which Dodds and his collaborators were led to the striking discovery of potent synthetic oestrogens, or to dilate on the proved value of these substances in medical and veterinary practice. I will only remark that as far back as 1933 Cook and Dodds noted that certain carcinogens exhibited oestrogenic properties, and the oestrogen-androgen relationships with various forms of cancer are now widely recognized and discussed. Arising from this, several American groups, and especially Huggins, were led to try stilboestrol, either as a substitute for or in conjunction with orchidectomy.

in cases of cancer of the prostate. The early results were highly encouraging, but later experience suggests caution.

Inquiries which I made when in America in August of 1945 elicited that about 80% of the patients experienced marked improvement with retrogression of the tumours and repair in many cases. However, the tumours reappeared at various intervals in the majority of the cases, but some 20% remained cured after two years. If that is a fair statement and my arithmetic is correct, it means that at least two men in every hundred over 50 years of age will have reason to be grateful for the discovery of stilboestrol.

Modern Chemotherapy

At the present time the development of chemotherapy is no longer a question of the blind preparation of a series of related compounds to be tested and reported on as good, bad, or indifferent. That system went far to justify the remark of a physiologist at a committee of which I was chairman, that he "thought they had now devised an excellent system for turning down the substances produced by the chemists." Thanks to the discoveries of Woods and Fildes and others, we try to find some rational basis for chemotherapy and, be it right or wrong, a working hypothesis is invaluable. For example, the discovery of paludrine by Curd and Rose followed stages suggested by analogies in constitution to known active substances, as well as by a hypothesis of the mode of action of anti-malarials. I commend their paper to your attention as an outstanding example of intelligently guided approach in this type of research. Incidentally, this is an opportunity to recognize with gratitude our debt to workers in the laboratories associated with chemical industry. Bayer 205, neosalvarsan, pamaquin, mepacrine, paludrine, prontosil, and sulphapyridine are a few examples of a long list of valuable agents which we owe to industry. Another modern development is the attention which is paid to the ease of absorption of the agents, their distribution in the body, the metabolic changes they undergo, and the side-effects they produce.

Hence successful medico-chemical research depends on effective co-operation, and this is most easily achieved when those trained in the different disciplines work under one roof.

For practical reasons, such as the dangers of amateur bacteriology and the upkeep of animal-houses, the chemist is normally the migratory component. But it is not enough to ensure that every medical research institute is equipped with a staff of chemists. The biologist is the first to encounter the problems, and even when they are clearly of a chemical nature there is often a serious lag before the appropriate chemist can make his contribution. In this respect we have compared rather unfavourably with some other countries.

Conclusion

Finally, I think that steps should be taken to improve the teaching of chemistry to medical students by drastic revision of the syllabus and by better laboratory facilities. In this way we may quicken the interest of medical men in general in developments which are sure to assume greater and greater importance. I venture to think, too, that a quicker route to medical scientific research should be open to a limited number of promising students, without the loss of the prestige of a medical qualification. That, I know, is a very thorny problem, and its solution would involve some break with tradition.

In some quarters faith in the eventual full success of the applications of chemistry to medicine is regarded as evidence of a materialistic outlook, and the defects of chemotherapy, as at present practised, are eagerly emphasized. Interference with physiological functions and the encouragement of resistant strains doubtless exist, but who can deny that mercury, salvarsan, sulphanilamide, sulphadiazine, and penicillin are milestones in a march of progress and that, without making extravagant claims to comprehend the whole field of medicine, the biologist and the chemist, hand in hand, can still do much more to alleviate the sufferings of humanity?

The Bureau of Current Affairs, 117, Piccadilly, London, W.1, has now produced the first numbers of its fortnightly publication, *Current Affairs*, which is available to civilian subscribers at 8s. 6d. per annum as well as to the Services; No. 3 comprises an article by Ritchie Calder entitled "Health of a Nation."

LUMBO-SACRAL ROOT PAIN

BY

J. MacD. HOLMES, M.D., M.R.C.P.

Physician, Staffordshire General Infirmary; Consultant Physician,
Wrexham and East Denbighshire War Memorial Hospital

AND

B. R. SWORN, M.B., F.R.C.S.

Surgeon, Staffordshire General Infirmary

It is now possible in most cases of "sciatica" to make a reasonably accurate diagnosis of the lesion responsible for the pain. A turning-point was the paper of Mixter and Barr (1934), reporting a series of cases in which protrusion of the intervertebral disks had caused pressure on the lumbar nerve roots and describing the diagnosis of disk protrusion by means of myelography. The occurrence of disk protrusion had been reported previously, but had not been regarded as sufficiently important or frequent to have much bearing on such a common condition as "sciatica."

Primary or idiopathic sciatica was for a long time accepted as a distinct clinical entity, and it was perhaps natural that clinicians should expect to find a common pathological basis in the majority of cases. Thus Dejerine thought that sciatic neuralgia was due to an inflammation of the lumbo-sacral nerve roots, which he called "radiculitis," and Sicard and Forestier suggested the term "funiculitis" for an inflammation of that part of the nerve traversing the intervertebral canal between the root and the plexus. With the increase in the use of x rays, the frequent occurrence of abnormalities of the lower lumbar vertebrae was noticed. Goldthwait of Boston postulated, more especially, the various degrees of sacralization of the fifth lumbar vertebra as the commonest cause of sciatica. Later Putti regarded arthritis of the intervertebral joints as the most common cause. Others have considered the condition to be a manifestation of myofascial "rheumatism" or "fibrositis." Since the recognition of the importance of disk prolapse it has been said that, except for an occasional cauda equina tumour, all cases of primary sciatica are due to disk lesions (Dandy, 1943).

In spite of these opinions we think there are a variety of lesions and these affect different parts of the nerve. Within the spinal canal pressure on nerve roots is almost certainly the commonest cause of symptoms, while arthritis of the intervertebral joints may be the most frequent lesion affecting the nerve roots in their course through the intervertebral foramen. Fibrositis and allied myofascial conditions are probably responsible for involvement of the nerves after they have emerged from the vertebral column. There is little evidence that inflammation of the main trunk of the nerve is a cause of sciatica, and Symonds (1943) is probably correct in saying that the sight of an inflamed and swollen sciatic nerve "trunk" "has never yet been granted to human eyes."

There is a tendency for each of the three main levels of nerve involvement to show a different clinical picture, but nevertheless differential diagnosis is no easy matter. Lesions of the nerve beyond the vertebral column are associated with chronic lumbar pain, and pain along the course of the sciatic nerve is seldom severe or early. The finding of "trigger points" of tenderness in the lumbar muscles is frequent in myofascial lesions, and is of considerable diagnostic significance. Lumbar pain alone also occurs for long periods before the onset of sciatica in arthritis of the intervertebral joints. The sciatic pain in this condition is not usually severe, and is often brought on by exercise and readily relieved by rest. On the other hand, muscle-wasting in the leg may be marked, and loss of power in dorsiflexion of the ankle, and even foot-drop, are seen more often than in either of the other types, with the exception of tumours of the cauda equina.

Where there is involvement of the nerve roots within the spinal canal lumbar pain may also be the first symptom; but this is not usual, and the sciatic pain soon becomes the dominant symptom. More often the sciatica is present from the onset, and may be very severe. In nearly every case there is exacerbation of the pain on coughing, sneezing, or other

similar strain; this we regard as the most important single symptom pointing to a lesion involving the root within the spinal canal. Paraesthesiae in the dermatome supplied by the affected root are of great diagnostic value, but it is well known that all the symptoms may be intermittent, particularly in cases of disk prolapse. The neurological signs are also intermittent and variable. Their diagnostic value will be discussed later.

Classification of a Series of 50 Cases

Most of our present series of cases are those we considered to have some condition affecting a lower lumbar or first sacral nerve root within the spinal canal. We have included a few cases in which we decided to operate because of intractable or recurrent pain, although they did not fulfil all our diagnostic criteria. It is not surprising that our results in this latter group are unsatisfactory, but we were interested to find, on reviewing the cases, that, in all in which we had made a confident diagnosis of a lesion affecting the posterior roots, at least a considerable measure of relief followed operation—in spite of the fact that in some of them we had found no visible lesion.

TABLE I.—Types of Lesion found at Operation (50 cases)

	Cases
1. Ruptured intervertebral disk	27
2. Tumours of the cauda equina	3
3. Hypertrophy of ligamentum flavum following lumbar puncture	2
4. Ruptured ligamentum flavum	1
5. "Radiculitis"	5
6. Transverse defect in myelograms. "Disk projection"	2
7. No lesion found:	
With signs of root lesion	6
Without signs of root lesion	4

This classification of our cases is based upon the findings at operation, although we are well aware that a surgeon's findings may not be completely reliable, since he is likely to find only lesions which are obvious or with which he is familiar.

Of our cases 54% were lesions of the disk, comprising three main types. The commonest is one in which a portion of fibrocartilage is avulsed from the posterior margin of the disk and is often lying free in the spinal canal. It may, however, be in front of the posterior common ligament—if that is intact—and be found only after incising the ligament, although its presence is often obvious from the backward displacement of the latter. In other cases the disk appears to have undergone degeneration, forming a softened material which extrudes through an incision into the posterior common ligament. Extrusion of the nucleus pulposus is the third type, and this may be difficult to distinguish from the previous one because the extruded material is soft and gelatinous. Characteristically this follows injuries to the disk by lumbar puncture.

Hypertrophy of the ligamentum flavum was found in two of our cases, although it has been denied by Dandy (1943) that it is ever the cause of root pain. In both our patients the hypertrophy followed trauma by a lumbar-puncture needle. In the first, a young woman, lumbar puncture had been carried out for spinal analgesia; and in the second, a young man, 18 lumbar punctures had been done 10 years before for the treatment of cerebrospinal meningitis. Symptoms—mainly of low backache, but with some occasional posterior crural pain—had come on gradually until he was almost crippled. Lumbar puncture in the fourth space gave a "dry tap." Injection of iodized oil higher up, and myelography, showed a complete block at the level of the lower border of the third lumbar vertebra. The diagnosis of thickening of the ligamentum flavum was confirmed at operation, when the ligament was seen to be enormously thickened, forming an "hour-glass" constriction of the theca. Excision of the thickened ligament was followed by filling of the lower theca with cerebrospinal fluid. Subsequently his pain slowly subsided.

There were five cases of what we have called "*radiculitis*." We have previously reported three of these under the title "sciatic neuritis" (Holmes and Sworn, 1945). The lesions found were of two types. There were three cases with gross swelling of the affected root but without any discoverable mechanical cause. It is true that oedema and swelling of the root may be associated with a ruptured disk, but we have never seen them to anything like the same degree. In one of our patients—following the suggestion of Burns and Young (1945)—that in the lower lumbar region a nerve root may be affected by the disk above—we explored the fourth lumbar disk imme-

diately above. No lesion was found; but the contrast between the normal and the enlarged roots was considerable. In two patients the root was normal in size, but there were adhesions between it and surrounding structures, particularly anteriorly and nothing else abnormal was found. It seems possible that these two cases may represent a later stage on the first type. The pathology in this group of five cases is obscure. The gross oedema and adhesions suggest inflammation, but against this are the history of trauma in all but one case and no change in the cerebrospinal fluid suggestive of inflammation.

The occurrence of almost complete transverse filling defects in the myelogram, with no lesion discovered at operation, has previously been noted. Hyndman, Steindler, and Wolkin (1943) regard these as false defects, but say that "the results of operation have been as favourable as when a herniated disk has been found and removed." They also remark that from such cases "one might deduce that causes other than herniated disk may be responsible for root pain at the fourth and fifth lumbar vertebrae." We have had two such cases, both relieved by operation, one of which seems worth describing in detail.

A woman aged 50 was referred to us by Mr. D. Whitwright from the Orthopaedic Hospital, Stoke-on-Trent. She had suffered from low back pain for 25 years and intermittent left sciatica for the past five years. There was severe left-sided sciatic pain on coughing and sneezing. She had occasional "pins and needles" sensations on the outer border of the left foot. On examination Lasèque's sign was positive on the left side at 45°. There was no motor weakness or muscle-wasting. Slight impairment of sensation to pin-prick and light touch was present on the outer border of the left foot and external malleolus. The ankle- and knee-jerks were present and equal. Lumbar puncture revealed no subarachnoid block and a normal fluid with a protein content of 40 mg. per 100 ml. W.R. negative. Straight skiagrams of the lumbar spine showed no abnormality, but myelograms at intervals of two days revealed a constant transverse filling defect opposite the disk between L4 and S1. At operation the fourth and fifth lumbar laminae were removed. The fourth and fifth disks appeared normal and no definite protrusion could be seen or felt. The nerve roots also appeared normal. There was some relief from pain immediately after the operation, and then gradual improvement until three months later, when the patient said she was completely free from pain.

We believe that this type of case is due to "disk projection." Normally the disk projects a little further into the spinal canal than the vertebral body, and a slight exaggeration of this, especially in association with a rather short nerve root, might well account for the symptoms and also for the myelogram. Occasionally a similar myelogram is found with a wide herniation of a disk, and, although the filling defect is seldom so symmetrical, it may only be at operation that the two can be differentiated with certainty. We found no softening of the disks in these two cases. The important feature is that operation gives good results; though whether this is due to displacement of the root or to decompression is not clear.

Though in six cases with definite signs and symptoms of root irritation we found no lesion at operation, we are inclined to think that some lesion must have been present but overlooked. Two cases had what we thought was some thickening of the ligamentum flavum, but this may have been within normal limits.

Diagnosis

We are in agreement with Munro (1945), who sums up one of his articles by saying: "Clinical examinations lay the groundwork for suspecting the presence of a posterior herniation of a lumbar disk. Contrast myelography proves or disproves this suspicion, determines the level of the herniation, and leads to a minimal amount of surgery, should this be indicated." We might add to this that myelography is the only satisfactory procedure, except operation, for revealing the various causes of root compression. The need for it will of course depend upon the relative frequency of disk-rupture and other lesions, but since we have a high proportion of the latter in our series we regard myelography as of the first importance. We have used it in every case in which operation has been seriously considered, and we do not think that it has affected any of our patients adversely. In most cases the iodized oil (neohydriol, fluid) has been removed by needling at the end of operation, and in some patients who did not come to operation we have removed the oil by the method of Kubik and Hampton (1941), although it is not always easy to obtain complete removal.

Table II gives the frequency of the clinical signs and symptoms in our series of 50 cases and illustrates our finding that the signs and symptoms in cases of "sciatica" cannot be relied upon to determine the type or exact level of the lesion. Increase in pain in the back of the leg on coughing or sneezing is the most valuable symptom indicating that a nerve root is affected within the spinal canal, but is of course not conclusive. It is true that in many patients a diagnosis of disk protrusion may be made from the history and clinical signs alone. Definite neurological signs, such as sensory loss in the fifth lumbar or first sacral dermatome, loss of ankle-jerk, motor weakness, and muscular wasting, are extremely valuable when present, but are very variable in their incidence even in cases of long standing. We are of the opinion that much greater accuracy is obtained from myelography.

TABLE II—Clinical Data in Groups of Cases with Disk Protrusion, with Other Lesions, and with No Discoverable Lesion

Clinical Data	Disk Protrusion	Other Intraspinal Lesions	No Lesion Found
Males	24 (50%)	10 (77%)	7 (50%)
Females	3 (11%)	3 (23%)	3 (50%)
History of injury or trauma	14 (51%)	9 (69%)	5 (50%)
Posterior crural pain	27 (100%)	12 (92%)	8 (100%)
Sensory impairment in dermatome	15 (55%)	9 (69%)	3 (50%)
Abnormal reflexion of ankle-jerk	16 (59%)	5 (38%)	4 (40%)
Deep tenderness in back or thigh	3 (11%)	6 (46%)	2 (50%)
Symmetrical weakness	3 (11%)	4 (31%)	1 (50%)
Lasèque's sign	26 (96%)	12 (92%)	9 (100%)
Unilateral	23 (85%)	5 (38%)	9 (100%)
Bilateral	3 (11%)	7 (53%)	—
Intermittent posterior crural pain on coughing	26 (96%)	12 (92%)	6 (100%)
Sciatica	8 (30%)	7 (53%)	3 (50%)
Major sacral nerve roots	1 (4%)	4 (31%)	1 (100%)
Normal subarachnoid block	1 (4%)	4 (31%)	—
Positive myelogram	25 (92%)	12 (92%)	2 (50%)

Percentages are given to the nearest whole number.

Of the disk protrusions, 20 were of the disk between L5 and S1; 6 were of the disk between L4 and L5; and in one case there were three protrusions—at L3 to 4, L4 to 5, and L5 to S1, with spinal subarachnoid block.

Results of Myelography

In the following summary a "positive" myelogram means that a filling defect was present in the iodized-oil column. The abnormality of filling varied from small defects in the region of the "axillary pouches" of the nerve roots to large notched or transverse defects in the main column of oil.

1. *Disk Protrusions*.—Myelogram positive in 25 cases; doubtful in two cases.

2. *Tumours of the Cauda Equina*.—Myelogram positive in all three cases, but diagnosis had previously been made from the presence of subarachnoid block and increased protein content of the C.S.F. Myelograms defined the limits of the tumours.

3. *Hypertrophy of the Ligamentum Flavum following Lumbar Puncture*.—Myelogram positive in both cases. "Hour-glass" defects were present, with complete subarachnoid block in one case.

4. *Ruptured Ligamentum Flavum*.—A small notched defect was seen in the one case.

5. "*Radiculitis*"—Positive in four cases, negative in one.

6. "*Disk Protrusion*."—Transverse defects in both cases.

7. *No Lesion Found*.—(a) In the two cases of doubtful thickening of the ligamentum flavum one myelogram was positive. (b) In the other four cases with signs of root irritation one was positive, two doubtful, and one unsatisfactory owing to the patient being in severe pain and unable to be manipulated. (c) The four cases without signs of root irritation all had negative myelograms.

Treatment

There is no doubt that most cases of "sciatica" will clear up spontaneously, or can be cured or relieved by relatively simple measures without resort to surgery. Rest in bed, splinting, physiotherapy (particularly the application of heat), injection of "trigger points" with local analgesic, and epidural injections of saline or local analgesic, all give successful results. There is also no doubt that a small number of cases are unaffected by such measures or suffer from recurrence of pain at intervals. It is not always satisfactory to temporize and attempt simple treatment in every case. The condition may be progressive, as in spinal tumour. Even in cases of disk protrusion a sudden increase in the protrusion may sometimes cause an irreversible paraplegia. It is, moreover, important to most patients that

they should return to work and be free from disability as quickly as possible.

We have therefore made a complete clinical and radiological examination of all our patients with sciatica, including lumbar puncture with manometry and examination of the cerebrospinal fluid. If the presence of root irritation has been suggested, or if pain has been severe or of long duration, we have discussed the possibility of operation. If operation has seemed necessary, and has been agreed to by the patient, myelography with iodized oil has been carried out. If the myelography has been positive operation has been performed, but in a few cases we have operated, in spite of negative myelograms, because of severe and intractable pain.

Laminectomy may be necessary for extensive lesions, but in most cases of disk rupture we have used the interlaminar approach, usually combined with removal of the lower border of the upper lamina. This gives better access to the anterior part of the ligamentum flavum and to its lateral extension, the interpeduncular ligament. It is easy to remove the rest of the lamina if necessary, and this gives a good exposure of two roots. We find that our patients are little affected by this limited operation, and we usually allow them up after 12 days.

All of the 27 patients with disk protrusion were immediately relieved of pain. There has been one recurrence of protrusion 18 months after operation, and a second operation was done for this, with complete relief. Of the other conditions described, it is interesting to note that in all cases with a positive myelogram improvement followed operation. One case of spinal tumour showed signs of recurrence six months after operation. In the cases with negative myelograms no appreciable relief followed operation, but no patient was worse.

Summary

Fifty cases of lumbo-sacral root pain have been studied clinically, radiologically, and at operation, and the findings are described. In 54% of the cases the symptoms were due to protrusion of the fourth or fifth lumbar intervertebral disk, but we have described several other lesions which were found at operation.

Apart from operation, myelography is the only satisfactory diagnostic method for revealing and locating the lesion.

MEDICAL RESEARCH IN EIRE

The Medical Research Council of Ireland has issued its report for the year 1945 from 85, Merrion Square, Dublin. The grant from the Hospitals Trust Board, guaranteed by the Minister for Local Government and Public Health for three years from January, 1944, was £5,000. As the period of this allocation of money will expire at the end of 1946 the Council has approached the Minister to make a substantial increase in the annual grant and to guarantee it for a much longer period. A big increase in applications for fellowships and studentships is anticipated now that more workers are becoming available to devote themselves to research, and it is hoped by the end of 1946 to have enough information to allow it to make definite proposals to the Public Health authorities for keeping this disease under control in the area. An investigation into the typhoid carrier condition was continued until the end of July, and the investigation into the chemotherapy of tuberculosis is progressing. By June of last year the Council had relinquished all control over the distribution and use of penicillin, the supply position to Eire having by that time become adequate for all requirements. The Committee appointed by the Council to advise the Minister for Local Government and Public Health on the establishment of dietary standards suitable to the Irish population held five meetings and submitted a detailed memorandum. Arrangements have been made for training field workers in methods necessary for carrying out the survey. During the year two studentships, five whole-time fellowships, and one part-time fellowship were awarded, and a number of grants-in-aid were authorized. The report concludes with a summary of work done by grant-holders during 1945.

TREATMENT OF SONNE III BACILLARY DYSENTERY AND BACILLARY DYSENTERY ("CLINICAL") WITH PHTHALYL SULPHATHIAZOLE

BY

J. BRODIE, M.D., D.P.H.

Lecturer in Bacteriology, University of St. Andrews, University College, Dundee

R. P. COOK, M.B., D.Sc.

Lecturer in Biochemistry, University of St. Andrews, University College, Dundee

CONSTANCE F. DRYSDALE, M.B., B.Sc.

Senior Resident Medical Officer, King's Cross Hospital, Corporation of Dundee

AND

D. G. McINTOSH, M.B., D.P.H.

Senior Assistant Medical Officer of Health, Corporation of Dundee

In a previous publication (Jamieson, Brodie, and Stiven, 1944) the clinical and bacteriological results obtained in 200 confirmed cases of bacillary dysentery of mixed type in Dundee were given. Although sulphaguanidine was found to produce results slightly superior, both clinically and bacteriologically, to those obtained with aperients and chalk, 30% of the cases treated with this drug were still bacteriologically positive in convalescence.

The present paper gives the results obtained by the treatment of 48 cases of Sonne III bacillary dysentery and 40 cases of "clinical" bacillary dysentery (i.e., cases showing blood and mucus in stools but from which no pathogenic organism was isolated) with phthalyl sulphathiazole. A note is also included on the possible prophylactic effect of the drug in a case which was cross-infected with Sonne III dysentery while convalescing from paratyphoid B fever.

Selection of Cases.—A specimen of faeces from each case admitted to King's Cross Hospital, Dundee, during the period August, 1944, to June, 1945, with a diagnosis of bacillary dysentery was examined bacteriologically on each of three successive days. Four days after cessation of treatment with phthalyl sulphathiazole, and provided clinical cure (see below) had been established, specimens of faeces were examined bi-weekly until three successive negative results were obtained. Cases yielding one or more positive results for the Sonne III bacillus either initially or during convalescence were placed in the bacteriologically confirmed group of cases: those yielding consistently negative results were placed in the clinical group.

Clinical Features.—Thirty-two of the 48 Sonne III cases and 28 of the 40 clinical cases were under 10 years of age. As in the previously reported cases, pyrexia was not a feature of the illness. Eight of the 48 Sonne III cases and one of the 40 clinical cases had a temperature greater than 100° F. (37.8° C.). In the Sonne III cases the stools showed blood and mucus in 30 and mucus in 18. Blood and mucus were present in the faeces of each case in the clinical group.

Method of Treatment.—Tablets of phthalyl sulphathiazole were crushed and given 4 times daily in water. Abundant fluids were administered by mouth, and a light diet was given during the first few days. The dosage used (see Table I) was one-half that employed for sulphaguanidine, on account of the lower solubility of phthalyl sulphathiazole. No toxic effects were observed in the 88 cases treated.

TABLE I.—Dosage of Phthalyl Sulphathiazole

Age in Years	Grammes per Day					Total in Grammes
	1st	2nd	3rd	4th	5th	
0-2	3	1	1	1	1	7
2-5	5	2	2	2	2	13
5-12	10	3	3	3	3	22
Over 12	15	4	4	4	4	31

Clinical Results of Treatment

Clinical cure was accepted as established on the disappearance of mucus and/or blood from the stool and return to normal consistence, maintained for a minimum period of 72 hours. The average periods required for clinical cure, after

the beginning of treatment, were: Sonne III cases, 8.73 days; clinical cases, 9.83 days. The least and greatest periods were respectively: Sonne III cases, 2 and 35 days; clinical cases, 3 and 21 days. Ten (20.8%) of the 48 Sonne III cases yielded a positive bacteriological result in convalescence (i.e., after the establishment of "clinical cure"). Relapse, which was regarded as the reappearance of mucus and/or blood in the stool after initial disappearance following treatment, occurred in 25 of the 48 Sonne III cases and 20 of the 40 clinical cases.

We were afforded the opportunity of testing the possible prophylactic effect of phthalyl sulphathiazole on the following patient, who was cross-infected with Sonne III bacillary dysentery.

A male child, aged 2½ years, who was convalescing from an attack of paratyphoid B fever and whose urine and faeces were positive for *B. paratyphosus* B, was given a total of 14 g. of the drug during 5 days (first day, 6 g.; next 4 days 2 g. daily). On the first day of treatment, and before any drug effect could have occurred, faeces and urine were reported negative for the first time. During the course of treatment, and for 7 days after cessation, daily specimens of urine and faeces were examined bacteriologically and negative results were obtained for *B. paratyphosus* B. Four days after the beginning of treatment the child developed diarrhoea, with blood and mucus in the faeces, and a culture of Sonne III bacillus was obtained. The drug did not appear to modify the course of the Sonne III infection. The stools were loose and contained blood and mucus for 10 days. Thereafter convalescence was normal and the faeces and urine yielded negative results for both the Sonne III bacillus and *B. paratyphosus* B.

Estimation of Phthalyl Sulphathiazole in Blood, Urine, and Faeces

On account of its low solubility considerable difficulty was experienced in estimating phthalyl sulphathiazole in body fluids and excretions. It should be emphasized that the values given are to be regarded as minimal. Whatever the shortcomings of the methods, the results from the faeces show clearly that the amount of phthalyl sulphathiazole as estimated is more than sufficient to saturate the water contained in the faeces, and hence the gut, with it, and the blood and urine analyses indicate that a small but definite absorption of the drug occurs.

To illustrate the difficulties a short account of the methods is given. The actual method of estimation employed was colorimetric, and was based on that of Bratton and Marshall (1939). The values given are for free phthalyl sulphathiazole; no estimations were made for the conjugated compound.

TABLE II.—Concentration of Phthalyl Sulphathiazole (PST) in Faeces, Urine, and Blood

Standard Solutions.—The solubility of phthalyl sulphathiazole at neutrality is less than 200 mg. per litre—i.e., less than 0.02 g. per 100 ml. A stock solution was, however, made by dissolving 200 mg. in 1–2 ml. N/10 alkali and making up the volume to 1 litre. Standards were made from this stock solution, which was kept at 2°C., by diluting 1, 2, and 4 ml.

to 100 ml. after the addition of 20 ml. of 10% trichloroacetic acid: 10 ml. of these dilutions contain respectively 0.02, 0.04, and 0.08 mg. phthalyl sulphathiazole. This range of standards was used throughout.

Blood.—The phthalyl sulphathiazole was determined on the trichloroacetic acid filtrate.

Urine.—A known amount was diluted to 100 ml. after the addition of 20 ml. of trichloroacetic acid, and a 10-ml. aliquot was removed for estimation.

Faeces.—On account of the low solubility of phthalyl sulphathiazole a small amount of faeces to a large volume of extracting water had to be used. Two grammes of faeces were suspended in 1,000 ml. of water and the whole mass digested at 60°C. for 2 hours. At the end of this time 1–2 ml. of N/10 sodium hydroxide was added and the contents well shaken. Aliquots of 5, 10, and 20 ml. were then withdrawn and each separate aliquot made up to 100 ml. after the addition of 20 ml. of 10% trichloroacetic acid. The acid mixtures were filtered and a 10-ml. aliquot was withdrawn in each case for estimation.

In Vitro Experiments with Phthalyl Sulphathiazole

A variety of micro-organisms were exposed to the action of phthalyl sulphathiazole at 37°C. for 24 hours. The media consisted of the C.C.Y. agar of Gladstone and Fildes (1940), semi-solid C.C.Y. agar, and Douglas broth, all having been saturated with phthalyl sulphathiazole before inoculation. Control tubes without phthalyl sulphathiazole were also employed. The micro-organisms used were: two strains each of *B. typhosus*, *B. paratyphosus* B (one of which had been isolated from Case 3—see Table II), *B. coli* (one strain each from a urine and a water-supply), and *B. dysenteriae* Flexner; and one strain each of Sonne III bacillus, *B. dysenteriae* var. Newcastle, and *B. proteus* X 19. Appreciable growths of all these bacteria were obtained on the C.C.Y. agar, especially *B. typhosus*, *B. coli*, and *B. paratyphosus* B, but in no instance was the growth as heavy as on the control tubes. It was noted that, whereas *B. proteus* swarmed well on the surface of the control tube, no swarming occurred when the agar contained phthalyl sulphathiazole.

When the semi-solid C.C.Y. agar and Douglas broth tests were examined it was noted that the bacteriostatic influence of the drug was more pronounced. Indeed, some of the bacteria failed to grow. Those which failed to grow by either cultural method were one of the Flexner strains, the Sonne III bacillus, and the *B. coli* from the urine.

During the *in vitro* experiments it was noted that phthalyl sulphathiazole was more soluble in Douglas broth than in water. Indeed, when enough phthalyl sulphathiazole was added to yield a 0.5% content, examination of the filtered fluid showed the presence of 0.4% of the drug.

TABLE III.—Comparison of Treatments for Bacillary Dysentery

Treatment	No. of Cases		Av. Time in Days Required for "Clinical Cure"		Cases Positive Bacteriologically in Convalescence			
					Sonne III		Total	
					No.	%	No.	%
Apocynins	11	50	6-3	6-5	4	36.4	25	50

Phthalyl sulphathiazole	43	—	8-73	—	10	20.8	—	—

Discussion

The paper by Jamieson, Brodie, and Stiven (1944) dealt with 200 cases of bacteriologically confirmed bacillary dysentery of mixed type, of which 39 were Sonne III infections. In Table III we have contrasted the effects of various treatments in their cases with the effect of treatment with phthalyl sulphathiazole. The results indicate that phthalyl sulphathiazole is the least effective agent in producing clinical recovery, although the number of cases positive bacteriologically in convalescence is less than those recorded by the other methods. Our findings may also be compared with those of Swyer (1943), who treated 57 cases of Sonne dysentery, 48 of which patients were aged 10 years and less, with sulphapyridine; 35 cases—25 of them

aged 10 years and less—were used as controls. Swyer states that there was little or no toxæmia or dehydration in either group. In the treated cases only 4 of the 57 had pyrexia ranging from 100 to 102° F. (37.8–38.9° C.) and lasting 1 to 3 days, while in the control group similar pyrexia occurred in 13 of the 35 cases. As regards both age and clinical features these cases offer a fairly satisfactory group for a broad comparison with our cases. The stools remained clinically abnormal in the treated group for an average period of 9 days, which is in agreement with our findings, compared with 20 days for the control group. Owing to the different standards used, it is not possible to compare our bacteriological results with those of Swyer, who found that in the chemotherapy group the time required to obtain bacteriological clearance was 5 days, compared with 21 days for the control group.

The high incidence of relapse (25 of 48 Sonne III cases, 20 of 40 clinical cases) is considerably greater than that noted by Jamieson, Brodie, and Stiven (1944), who found that relapse was fairly constant in their three groups of cases, the figures being as follows: 10 of 100 cases treated with sulphaguanidine; 5 of 50 cases treated with aperients; and 4 of 50 cases treated with chalk. In the present investigation the criterion adopted for relapse was a very rigid one: any patient showing an amount of mucus other than a mere trace was designated a clinically relapsed case. Of 25 cases which relapsed 7 (28%) yielded a positive bacteriological result in convalescence, compared with 3 (13%) of the 23 cases which did not relapse.

Owing to the mild nature of the majority of cases of bacillary dysentery the effect of different methods of treatment is difficult to evaluate—a fact to which Scadding (1945) has drawn particular attention. Brewer (1944) refers to 16 clinically recovered cases of Sonne dysentery, 9 of which had already received sulphaguanidine and 7 symptomatic treatment. So far as clinical cure was concerned, sulphaguanidine had not appeared to influence the course of the disease. He found that subsequent treatment with 44 g. of succinyl sulphathiazole (sulphasuxidine) over 5 days was effective in producing a negative stool in each of the 16 cases except one which needed two such courses. Hardy, Burns, and De Capito (cited by Poth and Ross, 1944) found that succinyl sulphathiazole was effective in preventing the development of bacillary dysentery carriers. Scadding (1945) cites the report by Roberts and Daniells in which 89 mild Flexner cases treated with succinyl sulphathiazole showed no significant difference compared with 136 similar control cases, except that there was a reduction in the convalescent carrier rate of the treated cases. Scadding's (1945) observation that succinyl sulphathiazole and sulphadiazine did not give results significantly superior to sulphaguanidine led to the institution of an investigation which showed that there was no statistical difference between sulphaguanidine-treated cases and untreated control cases so far as duration of diarrhoea and length of stay in hospital were concerned. Fairbrother (1944) states that although Sonne III dysentery is of mild type the carrier state after clinical recovery is common. He records the significant observation that approximately 60% of 76 Sonne cases which received no sulphonamide but only ordinary routine treatment became bacteriologically clear within three weeks. When employed in cases which had become carriers succinyl sulphathiazole and sulphaguanidine did not yield satisfactory results. Vollum and Wylie (1946), who claim that succinyl sulphathiazole is the best available drug for the control of Sonne dysentery, suggest that the unsatisfactory results obtained by Fairbrother were due not to persistence of Sonne infection but to reinfection; but, as Fairbrother (1946) points out in reply, the failures in his series were adults under Service conditions who were in hospital (isolated in side-rooms) during treatment. *In vitro* experiments by Fairbrother (1944) showed that Flexner and Sonne strains were inhibited by succinyl sulphathiazole, while sulphaguanidine was relatively ineffective. This confirmed the earlier work of Brewer (1944) so far as Sonne strains were concerned. Poth and Ross (1944) showed that phthalyl sulphathiazole possessed roughly twice the bacteriostatic effect of succinyl sulphathiazole in reducing coliform organisms in the intestinal tract of man. Poth (cited by Poth and Ross, 1944) found that phthalyl sulphathiazole was highly specific in the treatment of Flexner dysentery. It was further shown by Poth and Ross (1944) that patients suffering from diarrhoea, but in whom *Shigella para-*

dysenteriae organisms could not be identified, frequently responded to phthalyl sulphathiazole. Only rarely were positive stools found in follow-up cultures.

Since the criterion used by Fairbrother (1944) for bacteriological cure (12 successive daily negative cultures) is a more stringent one than that used in this investigation our results are not comparable with his. They may be compared, however, with the earlier findings of Jamieson, Brodie, and Stiven (1944). As shown in Table III, the number of cases bacteriologically positive in convalescence, in the cases treated with phthalyl sulphathiazole, is considerably lower than those recorded both for their 39 Sonne III cases and for their 200 mixed cases.

Summary

The results of treatment of 48 cases of Sonne III dysentery and 40 cases of bacillary dysentery ("clinical") with phthalyl sulphathiazole are given. The average periods required for the establishment of clinical cure were 8.73 days for the Sonne III cases and 9.83 days for the "clinical" cases. The results obtained in the former group were inferior when compared with those obtained by Jamieson, Brodie, and Stiven (1944), who treated 200 mixed cases of bacillary dysentery, of which 39 were Sonne III infections, with sulphaguanidine, aperients, and chalk, the corresponding figures for clinical cure being 5.0 days, 6.5 days, and 6.0 days respectively for the total group, and 4.7 days, 6.3 days, and 7.6 days for the Sonne III cases. On the other hand, our results are in agreement with those obtained by Swyer (1943), who found that the stools of 57 Sonne III cases treated with sulphapyridine remained abnormal for 9 days, compared with 20 days for a control group of 35 cases.

The incidence of clinical relapse was high in the cases treated with phthalyl sulphathiazole, being found in 25 of 48 Sonne III cases and 20 of 40 clinical cases. Seven (28%) of the 25 cases which relapsed yielded a positive bacteriological result in convalescence, compared with 3 (13%) of 23 cases which did not relapse.

Ten (20.8%) of the 48 Sonne III cases treated with phthalyl sulphathiazole gave a positive bacteriological result in convalescence, which is considerably lower than the figures quoted by Jamieson, Brodie, and Stiven (1944). For their 200 mixed cases the figures were: sulphaguanidine cases, 30%; aperient cases, 50%; chalk cases, 52%. For their 39 Sonne III cases the corresponding figures were: 40.0%, 36.4%, and 61.1%.

Reference is made in the discussion to the fact that the mild nature of cases of bacillary dysentery renders evaluation of the effects of different therapeutic agents difficult. The observations of Fairbrother (1944) and of Scadding (1945) are especially apposite in this connexion.

The dosage of phthalyl sulphathiazole shown in Table I was based on age; and the results of analyses of faeces, urine, and blood showed that: (a) saturation of the gut contents was achieved; (b) small but definite absorption of the drug occurs. No toxic effects were observed in the 88 cases treated.

In vitro experiments showed that phthalyl sulphathiazole exerts a bacteriostatic effect against a number of intestinal organisms. A Flexner strain, a Sonne III organism, and a strain of *B. coli* were completely inhibited in semi-solid and fluid media containing the drug.

The results of the present investigation indicate that, while phthalyl sulphathiazole did not appreciably influence the clinical course of Sonne III dysentery, it reduced considerably the number of cases bacteriologically positive in convalescence.

We desire to acknowledge our thanks to Dr. W. L. Burgess, C.B.E., and Prof. Tulloch, O.B.E., for granting us facilities for this investigation, and to Messrs. May and Baker for kindly supplying the phthalyl sulphathiazole. We greatly appreciate the assistance given us by Sister Elder, of King's Cross Hospital.

A message from Washington states that to advance an expanding physical restoration programme the Office of Vocational Rehabilitation, Federal Security Agency, has acquired the services of five new medical officers and contemplates filling additional full-time posts in the fields of ophthalmology, hospital administration, tuberculosis, and psychiatric social work. Dr. Victor H. Vogel of Denver, surgeon in the U.S. Public Health Service, has been named chief medical officer of the Office of Vocational Rehabilitation.

BACTERIOLOGY OF STOMACH AND DUODENUM IN CASES OF PEPTIC ULCER AND GASTRIC CARCINOMA

BY

MARY BARBER, M.D.

AND

R. H. FRANKLIN, F.R.C.S.

(From the Departments of Surgery and of Pathology, British
Postgraduate Medical School)

Unexplained sepsis, which occasionally occurs after apparently straightforward cases of partial gastrectomy, may lead to the development of a subdiaphragmatic abscess or, more rarely, to general peritonitis and death. It has been noted that the tissues surrounding a chronic peptic ulcer are often oedematous, the neighbouring lymph-nodes may be enlarged, and in short the clinical picture may be one of inflammation. The present investigation was undertaken to determine whether any pathogenic bacteria were present in the stomach and duodenum at the time of operation.

The normal bacterial flora of the alimentary tract has been the subject of much work and even more discussion. Billroth (1874) demonstrated that the meconium of newborn infants was sterile and that bacteria appeared with the first yellow stools. Escherich (1885) confirmed this, and showed that the interval elapsing before the appearance of organisms was dependent on when the earliest feed was given. He also established the colon bacillus as the characteristic intestinal organism. Where these bacteria come from, and whether they enter via the mouth or the anus, were for some time subjects of conjecture. In 1900 Cushing and Livingood summed up the evidence then available and concluded that food was the most important source. More recently many studies have been made on the effect of diet on the intestinal flora. Cannon and McNease (1923) found that in rats on a high protein diet the pH of the contents of the caecum and colon was 7.0-7.1, and the bacterial flora consisted mainly of proteolytic types, whereas the addition of lactose lowered the pH of the intestinal contents and with an increasing acidity the proteolytic bacteria were replaced by aciduric organisms such as *B. acidophilus*. Sanborn (1931a, 1931b) studied the bacteria present in the faeces of adult patients in the Boston Psychopathic Hospital when on various diets. He stated that "a diet high in carbohydrate and one high in meat protein tend to simplify the aerobic flora, respectively, in the acidophilic and the colonic direction." He found, however, that the degree to which this transformation took place varied very much with different individuals, and he concluded that the normal intestinal flora was not simply dependent on age and diet, but was dependent also on the "metabolic characteristics" of the individual.

Action of Bacteria in the Alimentary Tract

Another aspect which has caused considerable controversy is the importance of bacteria in the alimentary tract. Levin (1899) says that Pasteur in 1880 posed the question whether bacteria are essential for digestion. Nuttall and Thierfelder (1895) succeeded in keeping alive and well for eight days a guinea-pig obtained by Caesarean section, confined in a sterile chamber, breathing sterilized air, and fed on sterilized milk. After eight days the animal was killed and the intestines were shown to be free from bacteria. Levin (1899) went to Spitsbergen to study the bacteriology of the Arctic regions. He investigated the intestinal contents of white bears, reindeer, and seals, and found them usually sterile. This he correlated with the great rarity of bacteria in the air and water of the Arctic. The latter contained less than one organism in 11 ml., as opposed to 600,000 per ml. in the Seine. Cohendy (1912) finally proved that animals normally having bacteria in their intestines can survive without them. He reared chicks under sterile conditions for from 12 to 40 days, and found that they developed as well as control chicks, although the food of the former was rather less well digested. For some time after this it was thought that bacteria in the intestinal canal served no useful purpose and were possibly even harmful. In the last few years, however, a new function has been assigned to them—

namely, synthesis of vitamins. The ability of many intestinal bacteria to synthesize members of the vitamin B complex *in vitro* is beyond doubt (see Burkholder and McVeigh, 1942). Evidence is now accumulating to show that the biosynthesis of vitamins in the human intestine is by no means negligible. Adolescent males kept on carefully controlled diets deficient in thiamine (Najjar and Holt, 1943) and riboflavin (Najjar *et al.*, 1944) continued in many cases to excrete these substances in normal quantities in the faeces. Ellinger *et al.* (1945) found there was a gross discrepancy between the intake and output of nicotinamide in healthy adults, and that the urinary secretion was reduced by 60%, if the subjects were given succinyl sulphathiazole (sulphasuxidine). From these experiments it cannot be concluded that the intestinal bacteria are necessarily beneficial, as under certain conditions *in vitro* many intestinal bacteria destroy vitamin C (Young, 1942; Young and James, 1942; Young and Rettger, 1943), and organisms of the *Pseudomonas* group will decompose nicotinic acid if that is the only organic compound in the medium (Koser and Baird, 1944). Benesch (1945) obtained a sample of mixed caecal flora from a patient with a caecostomy. He found that under aerobic conditions nicotinic acid was synthesized, and under anaerobic conditions two-thirds of the nicotinic acid present in the original medium was destroyed. Clearly the possible activities of bacteria in the intestines under different conditions are legion and remain a matter for speculation.

Antiseptic Properties of Gastric Juice

In contrast to the prolific flora of the large intestine, the stomach and early duodenum in the healthy adult are usually sterile, except just after a meal. Spallanzani (1783) was the first to draw attention to the antiseptic properties of gastric juice. He demonstrated that "les chairs enfermées avec le suc gastrique ne sont point sujettes à la pourriture." Cushing and Livingood (1900) reviewed a series of cases of gunshot wounds of the abdomen perforating the gut, and found that only those patients survived in whom the lesion was near the pylorus—lesions lower in the alimentary tract leading to peritonitis. This they attributed to the antiseptic action of the gastric juice. Hewetson (1904) gave himself cultures of *Staph. aureus* and *Ps. pyocyanea* via a stomach-tube and then examined samples of gastric juice every 15 minutes. The cocci were found to be killed in 30 to 45 minutes, and the bacilli in 60 to 90 minutes. He noticed no ill effects, and subsequently planted similar cultures in the stomachs of several patients with gastrotomies, obtaining similar results. Knott (1923) correlated the efficiency of gastric juice as a germicidal barrier with the concentration of free hydrochloric acid present, and determined the concentration of the latter necessary to kill various bacteria. He concluded that sporing bacilli and resistant coliforms would easily survive gastric juice; that the typhoid and dysentery group and staphylococci would survive only if the free hydrochloric acid content was low; that *Str. pyogenes*, *Str. viridans*, *C. diphtheriae*, and *M. catarrhalis* would pass through to the duodenum only in conditions approaching achlorhydria. Knott and Venables (1924) showed that in 90% of cases with normal gastric acidity the duodenal contents were sterile, whereas Knott (1927) found that 37 patients with pernicious anaemia and achlorhydria all had bacteria in the duodenum. Garrod (1939) showed that susceptibility to the bactericidal action of hydrochloric acid of any pathogenic bacteria entering the body via the alimentary tract varied considerably, and that gastric juice was more bactericidal than hydrochloric acid of equivalent strength.

In gastric disease it has repeatedly been shown that bacteria may actually multiply in the stomach. In 1842 Goodsir described a case "in which a fluid periodically ejected from the stomach contained vegetable organisms of an undescribed form." He described the bacterium in some detail, and suggested for it the name *Sarcina ventriculi*. Gillespie (1893) isolated 24 different organisms from the stomach by means of a stomach-tube. Hewetson (1904) seems to have been the first to study material taken direct from the stomach at operation. He took cultures from the stomach in 36 cases and from the jejunum in 29; 18 of the former and 16 of the latter were sterile. A variety of bacteria were isolated from the rest, but, owing to the fact that they caused no ill effects when injected into rodents, he concluded that they were harmless.

More recent work on the bacteriology of the stomach and duodenum has been carried out mainly to answer two questions: first, whether infection plays a part in the causation of peptic ulcers; and, secondly, whether post-operative sepsis is related to the bacteria present in the stomach at the time of operation. According to Bolton (1913), Böttcher in 1874 demonstrated bacteria in the edges and floor of gastric ulcers and suggested direct infection from the stomach cavity. That bacteria can produce stomach and duodenal ulcers in rodents has been shown by many workers. Some of the earliest results in this line are those of Lettulle (1888), with *Staph. aureus*; Chantemesse and Widal (1888), with a dysentery bacillus; and Charrin and Ruffer (1889), with a filtrate from *Ps. pyocyanea*. Rosenow and Sandford (1915) found streptococci (usually *viridans*) in a very high proportion of peptic ulcers, and Rosenow (1916, 1923) showed that a high percentage of these bacteria, and also cultures of *Str. viridans* isolated from dental infection in ulcer patients, had a "characteristic affinity" for the stomach and duodenum, leading to ulcers in these organs on injection into dogs, monkeys, rabbits, guinea-pigs, and mice, whereas streptococci isolated from other patients did so much less frequently. Similar results were obtained by Christophe (1922), Nakamura (1924), Haden and Bohan (1925), and Nickel and Hufford (1928).

Löhr (1924) was interested in the fact that the free fluid found in the abdomen after perforation of a peptic ulcer was frequently sterile. He studied the contents of the stomach and duodenum obtained at operation from 200 cases; the contents were sterile in 82% of 56 cases of gastric ulcer, in 92% of 40 cases of duodenal ulcer, and in only 78% of 46 cases of gastric carcinoma. Appelmans and Vassiliadis (1932) cultured portions of ulcer obtained at operation from 60 cases. Bacteria were isolated from 13 of 23 duodenal ulcers, 14 of 17 gastric ulcers, and all of 18 gastric carcinomas. The organisms isolated were, in order of frequency, staphylococci, streptococci, yeasts, coliform bacilli, *B. mesentericus*, and lactic acid bacilli. Seley and Colp (1941) investigated the bacteriology of the stomach and duodenum in a series of cases undergoing partial gastrectomy. Actual portions of mucous membrane of these organs were cultured with a view to determining whether post-operative sepsis could in some cases be attributed to bacteria present at the time of operation. Positive cultures were obtained in 7% of "gastric malignancies," 83.3% of gastric ulcers, 36.6% of duodenal ulcers, and 37.9% of secondary peptic ulcers. Bacteria regarded as pathogenic, including *Str. haemolyticus*, *Str. viridans*, non-haemolytic streptococci, *Cl. welchii*, and *Bact. li*, were isolated from 88% of the "malignancies" and 30% of the benign ulcers. The high percentage of pathogenic organisms in carcinoma cases was correlated with a low average gastric acidity, and the incidence of post-operative complications and mortality appeared higher in these cases. Priestley *et al.* (1944) examined the gastric contents taken at operation from 44 cases. The contents were sterile in 18 of 22 cases of duodenal ulcer, in 1 of 7 cases of gastric ulcer, and in none of 5 carcinomas. Test meals done before operation showed that bacteria were seldom isolated if the level of total gastric acidity was 40 units or higher. The organisms isolated were "green-producing streptococci," micrococci, and Gram-negative bacilli. In spite of this voluminous literature the number of studies where organisms were taken direct from the stomach and duodenum at operation and the bacteria isolated were fully identified is small.

Experimental Tests

In the present study swabs were taken from the mucosa of the stomach and duodenum at operation on a series of 50 patients undergoing partial gastrectomy. Each swab was inoculated on to two blood-agar plates, one of which was then inoculated aerobically and the other anaerobically. Bacteria appearing on these plates were isolated in pure culture and, where possible, identified. In most cases test meals were done before operation and a portion of ulcer was examined histologically.

Table I correlates the gastric condition with the number of positive bacteriological results; in 9 out of 10 cases of gastric carcinoma bacteria were isolated from the stomach alone or stomach and duodenum; the gastric ulcer cases show a lower proportion of positive results, and both swabs were sterile from all of 12 cases of duodenal ulcer.

Table II gives a list of the bacteria grown and the number of times each was isolated in cases of simple ulcer and carcinoma. The last column shows the highest concentration of

TABLE I

	Simple Ulcers			Gastric Carcinomas	Total
	Gastric Ulcers	Jejunal Ulcers	Duodenal Ulcers		
Stomach and duodenum sterile	12	0	12	1	25
Micro-organisms isolated from stomach; duodenum sterile	11	1	0	6	18
Micro-organisms isolated from stomach and duodenum	4	0	0	3	7
Total	27	1	12	10	50

TABLE II.—Micro-organisms isolated

Organism		Simple Ulcers	Gastric Carcinomas	Highest Conc. of Free HCl in Gastric Resting Juice
<i>M. albicans</i> ..	From stomach; 11 cases	9	2	61
<i>Str. viridans</i> ..	" stomach; 9 "	6	3	0
	" duodenum; 3 "	3	0	0

<i>Diphtheroid bacilli</i>	" stomach; 2 "	1	1	Not tested
	" duodenum; 1 case	1	0	0
<i>Staph. aureus</i> ..	" stomach; 2 cases	2	0	0
<i>Str. pyogenes</i> ..	" stomach; 1 case	0	1	0
(Lancefield Group A)	" duodenum; 1 "	0	1	0
Lactobacilli ..	" stomach; 1 "	0	1	0

free hydrochloric acid found in the resting juice, taken before operation, of any patient from whom that particular organism was cultivated. The non-haemolytic streptococci included typical *Str. faecalis* and other types. The coliform bacilli were mostly *Bact. coli*, but *Proteus* and *B. faecalis alcaligenes* were also isolated.

Discussion

M. albicans, non-haemolytic streptococci, and coliform bacilli were isolated from many patients who had a normal or high gastric acidity. All other bacteria were isolated only from cases where the test meal showed a condition approaching achlorhydria. In this series of 50 cases septic post-operative complications were no higher among the 25 cases with positive cultures than among the other 25. The isolation, however, of such organisms as *Str. pneumoniae*, *Staph. aureus*, and Lancefield A haemolytic streptococci makes it clear that bacteria in the stomach at the time of operation are a potential source of infection, and pre-operative medication might be advisable at least in those cases with low gastric acidity.

Summary

Swabs for bacteriological examination were taken direct from the mucosa of the stomach and duodenum at operation in 50 cases undergoing partial gastrectomy for peptic ulcer or gastric carcinoma. Bacteria were isolated from 16 of 40 cases of benign ulcer and 9 of 10 cases of carcinoma. Pyogenic cocci (*Str. pneumoniae*, *Staph. aureus*, and Lancefield A haemolytic streptococci) were isolated from 7 cases.

TREATMENT OF BRANCHIAL CLEFT CYSTS BY ASPIRATION AND INJECTION OF PURE CARBOLIC ACID

BY O

T. FRANCIS JARMAN, M.D.

Deputy Tuberculosis Physician, Welsh National Memorial Association;
Deputy Medical Superintendent, Cyma Tuberculosis
Hospital, Neath

The occurrence of branchial cysts is relatively rare. The most common mistake in diagnosis is to confuse the condition with an abscess resulting from breaking-down tuberculous glands. In a study of 42 branchial cysts and 9 branchial fistulae, in which incorrect diagnosis was made in 42% of cases, Shedden (1931) reports that 12% were diagnosed as tuberculous glands in the neck. Hamilton Bailey (1928) reports 11 cases of branchial cyst in which this mistake was made, and one very interesting case in which tubercle bacilli were found both in the wall of a branchial cyst and in its fluid contents.

Diagnosis

According to Shedden (1931) branchial cysts occupy a constant anatomical position. They lie in relationship to the deep surface of the upper half of the sterno-mastoid, and nearly always protrude around the anterior border of this muscle. Most commonly the centre of the cyst is opposite the greater cornu of the hyoid bone. In the six cases reported here the swellings were hard and tense, giving an impression of induration rather than of being cystic and fluctuant. Bailey (1923) remarks that all branchial cysts which give rise to symptoms are lined with squamous epithelial cells, and that so-called "mucous branchial cysts" lined with columnar epithelium are in reality cystic hygromas. He states, further, that the presence of cholesterol crystals in aspirated fluid is diagnostic of a branchial cyst. Two other factors, noticed when aspiration is performed, appear to me to indicate a branchial cyst rather than a tuberculous abscess: (a) that the fluid content is very thin, and (b) that the cyst can almost always be completely emptied at the first aspiration.

The cases here reported were diagnosed as tuberculous cervical adenitis, and were referred to me for treatment of that condition. The diagnosis of branchial cyst was subsequently made in each case on the finding of squamous epithelial cells during examination of aspirated fluid at the Central Tuberculosis Laboratory, Cardiff.

Treatment

The treatment generally recognized as being the only satisfactory one is complete excision (Shedden, 1931; Bailey, 1923, 1928; Baumgartner, 1933). Cutler and Zollinger (1933) report several cases of cervical fistulae and pilonidal cysts treated by a modified Carnoy's solution containing absolute alcohol 6 ml.,

chloroform 3 ml., glacial acetic acid 1 ml., and ferric chloride 1 g. Robitshke (1933) records a case of branchial fistula successfully treated in this way. Five of the six cases reported below were treated by aspiration followed by the injection of from 0.5 to 1 ml. of pure carbolic acid. In one case the cyst disappeared after a single aspiration without the injection of any sclerosing fluid, but recurred 8 months after this aspiration. Aspiration was made with a moderately fine needle, which was held carefully in place to receive the Record syringe containing the carbolic acid. After aspiration, which in every case caused complete flattening of the cystic swelling, the acid was injected with maximum rapidity in order to obtain a spraying effect with the carbolic on the lining of the cyst wall. Firm pressure was then maintained on the site of the emptied cyst for five or ten minutes.

Case Reports

Case 1.—A man aged 31 was admitted with a very large hard mass in the left side of the neck deep to the upper third of the sterno-mastoid; on Feb. 13, 1943, 25 ml. of rather thin yellowish fluid was aspirated and the swelling completely flattened. On Feb. 27 the swelling reappeared, and 5 ml. of fluid was aspirated. The laboratory report (Dr. Ruth Milne) on the aspirated fluid stated: "No acid-fast bacilli found. The presence of many epithelial cells suggests that the pus may be from a simple branchial cyst. The character of the fluid is also suggestive but not absolutely typical of this." March 20: Swelling very large and hard again; 20 ml. of fluid aspirated, and swelling completely flattened again; 0.5 ml. of pure carbolic acid injected. March 27: Swelling now very small. April 10: Swelling hardly palpable. May 1: Swelling completely gone. Seen in January, 1945, and March, 1946, the patient stated that there had been no recurrence.

Case 2.—A woman aged 41 was admitted on April 2, 1943, with a hard tense swelling in the right side of the neck; 10 ml. of brownish fluid aspirated from the cyst and swelling completely flattened. Laboratory report (Dr. Milne): "No tubercle bacilli. Squamous epithelial cells present in large numbers. Findings typical of a branchial cyst." This case was kept as a control and no carbolic acid was injected. The cyst showed no signs of filling up until Dec. 6. The swelling recurred, and by Jan. 10, 1944, had reached the same size as when originally seen. It was aspirated and 12 ml. of brownish fluid withdrawn. This fluid was again reported on as being characteristic of a branchial cyst. This time, however, 1 ml. of pure carbolic acid was injected after aspiration. Three months later only a small firm swelling was present near the anterior border of the sterno-mastoid. Jan. 29, 1945: No palpable swelling present. March 1, 1946: No recurrence.

Case 3.—A man aged 26 was admitted on Aug. 18, 1943, with a large hard tense mass in the upper half of the right side of the neck, deep to the sterno-mastoid; 12 ml. of thin greenish-yellow fluid aspirated from the swelling. Laboratory report on the fluid (Dr. Milne): "No tubercle bacilli present. Large numbers of squamous epithelial cells. Findings typical of branchial cyst." Sept. 4: Swelling up again; 6 ml. of fluid aspirated; 0.5 ml. of pure carbolic injected. Sept. 18: Swelling much smaller, but up again; 4 ml. of fluid aspirated; 1 ml. of pure carbolic acid injected. Dec. 13: Now has a small firm swelling near the anterior border of the sterno-mastoid. Jan. 10, 1944: A tiny hard nodule only is palpable. Jan. 29, 1945: No mass or nodule palpable. April 20, 1945, and March 1, 1946: No recurrence.

Case 4.—A young woman aged 22 was admitted on March 3, 1944, with a tensely fluctuant swelling in the upper half of the left side of the neck; 16 ml. of brownish thin fluid aspirated. Laboratory report on fluid (Dr. Milne): "No tubercle bacilli present. Large numbers of squamous epithelial cells observed. Findings typical of branchial cyst." April 28: Swelling up again; 18 ml. of fluid aspirated and swelling completely flattened; 1 ml. of pure carbolic injected. May 12, 1944: Small hard mass palpable. July 21: Swelling completely gone; nothing to palpate. Jan. 22, 1945: No palpable swelling. April 23, 1945, and March 1, 1946: Follow-up; no recurrence.

Case 5.—A young woman aged 23 was admitted on March 3, 1944, with a large tensely fluctuant swelling in the left side of the neck; 15 ml. of thin yellowish fluid aspirated from the swelling. Laboratory report on the fluid (Dr. Milne): "No tubercle bacilli; large numbers of squamous epithelial cells. Findings typical of a branchial cyst." March 10: 5 ml. of fluid aspirated; 1 ml. of pure carbolic injected. April 28: Swelling completely gone. May 26: Swelling still absent; nothing at all abnormal to palpate. Jan. 29, 1945: Swelling reappeared a week ago. A very hard swelling the size of a walnut present. Aspiration attempted but no fluid obtained. Diagnosis doubtful. Feb. 10: Swelling has disappeared; may have been a lymphadenitis. April 30: No palpable swelling. March 3, 1946: No recurrence.

Case 6.—A girl aged 12 was admitted on Dec. 22, 1944, with a fairly tense cystic swelling in the left side of the neck, deep to the

upper half of the sterno-mastoid; 25 ml. of buff-coloured fluid aspirated and swelling completely flattened. Laboratory report: "Fluid contains large numbers of squamous epithelial cells and is typical of a branchial cyst." Jan. 5, 1945: Swelling has recurred, but is not so large as when first seen; 12 ml. of fluid aspirated and swelling again completely flattened; 1 ml. of pure carbolic acid injected. Jan. 19, 1945: Swelling again present, but now very small and indurated. Feb. 9: A small firm mass, the size of a hazel nut, is palpable deep to the upper third of the sterno-mastoid. March 22: Swelling completely gone. April 30, 1945, and March 1, 1946: No recurrence.

Discussion

No untoward reactions of any kind have been encountered after this treatment. Shedden (1931) reports that iodine, alcohol, caustic potash, trichloroacetic acid, and mercuric nitrate have all been injected into branchial fistulas in attempts to close them, sometimes with fatal results after passage of these substances along the fistula into the mouth. I cannot find any reference, however, in the literature to the use of sclerosing solutions in the treatment of branchial cysts. Trail, in a personal communication in 1944, reported the disappearance of a branchial cyst following its aspiration and the injection into it of lipiodol for purposes of radiological study. It would seem that branchial cysts have no fistulous connexion with the mouth (Bailey, 1923). Baumgartner (1933), however, describes a form of "incomplete internal" fistula with an internal but no external opening which could presumably become cystic and in which the injection of pure carbolic acid might carry some risk. This is, I believe, far more of a theoretical than an actual practical risk, and one which could be overcome by careful scrutiny of the mouth after the injection of methylene-blue solution into the cyst.

The follow-up in these cases is too short to be certain that recurrence will not take place but is long enough to make such a conclusion reasonable.

Summary

Six cases of branchial cyst are reported. They were treated by aspiration followed by the injection of from 0.5 to 1 ml. of pure carbolic acid. In every case the swellings disappeared and have not, so far, recurred. One of the cases was first treated by aspiration alone, but the cyst recurred after 8 months. It was subsequently treated as above, and has not recurred since.

Medical Memoranda

Post-operative Mania treated by Continuous Intravenous Pentothal

Little has been written about the action and effects of sodium pentothal, even as a short-acting anaesthetic. By the following case it is hoped to illustrate the possibilities of prolonged narcosis produced and sustained by this drug. It would seem that modifications of the method as shown below may be used in the treatment of other disorders of a nervous nature.

CASE HISTORY

The patient, an ex-officer in the Merchant Navy aged 24, gave a history of peptic ulceration dating back to 1939. From September, 1943, to July, 1945, he had had four operations—two for perforations and one each for gastro-jejunostomy and laparotomy. After the last operation he was violent and confused, and had to be restrained, but this lasted for only 24 hours. He was left with no obvious mental trauma. After two months' hospital treatment a partial gastrectomy was performed in September, 1945.

Some facts involving the patient's psychological state are of interest. He underwent many hardships on the Murmansk convoys, and on one of these his ship was torpedoed. As a result he was very nearly drowned and lost the thumb and three fingers of his left hand. His wife had a baby four weeks before his present operation, and about the same time he lost the job which he had held since his discharge from the Service a year ago. He smokes 15 to 20 cigarettes daily, but takes no alcohol.

The patient is a well-built, healthy-looking man, introspective and rather "highly strung." He requires a lot of attention and is obviously "spoilt." His general physical condition is good. The handicap of his left hand does not worry him unduly, and he has

overcome it to a great extent. Examination of his C.N.S. revealed no abnormality. The day before his operation he was very well, and looking forward to the benefit which he was to receive from it. That night he slept well without sedation.

Sept. 7, 1945.—8.30 a.m.: Premedication—omnopon 1/3 gr. (22 mg.) and hyoscine 1/150 gr. (0.44 mg.). 10.10–11.30 a.m.: At operation the gastro-enterostomy was undone and a partial gastrectomy carried out. Anaesthesia was induced with intravenous pentothal 0.5 g., and thereafter he was given nitrous oxide, oxygen, and ether. Induction and anaesthesia were smooth and uneventful, and at no time was he cyanosed. 2.15 p.m.: Coming out of the anaesthetic; restless; omnopon 1/3 gr. 4 p.m.: Continuing restless; 4 dr. (14 ml.) rectal paraldehyde given without effect. 6 p.m.—2 a.m.: 14 gr. (0.1 g.) of morphine in 1/4-gr. (16-mg.) doses. Patient now very violent and having hallucinations of torpedoes and sensations of fear of drowning. A restraining sheet failed to control him.

Sept. 8.—3.15 a.m.: Omnopon 2/3 gr. (45 mg.) and hyoscine 1/75 gr. (0.87 mg.). Very little effect. Pulse rate rising, but colour remains good. 10.20 a.m.: As the patient's condition in some ways resembled delirium tremens 3 ampoules of vitamin B₁ were given intravenously. An hour later he was more violent than before. He was out of bed on several occasions, being almost uncontrollable. 12.40 p.m.: Slept for one hour after 33½ gr. (2.2 g.) sodium amylal intravenously. 2.50 p.m.: Slept for a further hour after 6 dr. (21 ml.) rectal paraldehyde, some of which was returned. 4.30 p.m.: Began to retch violently, then vomited some clotted blood. Was not obstreperous but quite uncooperative. Pulse and colour remained good. 6 p.m.: At this point it was agreed that he would have to be put to sleep or he would die from exhaustion. Since hypnotics were apparently useless, it was decided that sodium pentothal intravenously was the most effective and suitable narcotic. Consequently sleep was induced by the injection of 0.5 g. as for induction of anaesthesia. A glucose-saline drip was then set up, containing 1 g. of pentothal to 1 pint (568 ml.) of glucose-saline. The rate of drip was determined by the depth of the narcosis, 40 drops a minute being required on an average to keep him narcotized. 8.10 p.m.: A second pint, again containing 1 g. of pentothal, was begun. 10.45 p.m.: A third pint, containing 0.5 g. of pentothal, was begun.

Sept. 9.—1.30 a.m.: Drip discontinued; a total of 3 g. of pentothal had been given. He slept on for 3½ hours after the drip was stopped, remaining reasonably quiet until 8 a.m., when he again became violent; later he fell asleep for one and a half hours. 12.30 p.m.: The patient got out of bed, brushed all restraint aside, and ran into the corridor, where he collapsed exhausted. Sleep was again induced with 0.5 g. of pentothal, and the glucose-saline-pentothal drip reconstituted (1 g. to the pint as before). 3.20 p.m.: He was now kept under with 0.5 g. per pint, but this involved a faster rate of flow, and by 8 p.m., after having had 3 pints (1.7 litres) of fluid containing 2 g. of pentothal, signs associated with increased bronchial secretion became evident. Atropine 1/100 gr. (0.65 mg.) was administered. The concentration of the drip was then increased to 1.5 g. per pint, and a dripping-rate of 5 drops a minute sufficed to keep the patient narcotized.

Sept. 10.—By this time he had had 21 hours' continuous sleep (excluding the first occasion), with 4 g. of pentothal in 4 pints (2.3 litres) of glucose-saline. The drip was then discontinued. 12.15 p.m.: Beginning to waken. To prevent his regaining consciousness too quickly 6 dr. (21 ml.) of rectal paraldehyde was administered. 2.15 p.m.: Respirations becoming shallow and colour poor. Carbon dioxide and oxygen given in addition to strychnine 1/30 gr. (2 mg.). T. 103° F. (39.4° C.), P. 138, R. 32. 6–10 p.m.: Still unconscious. General condition very poor. One ampoule of nikethamide given hourly. T. 104.8° F. (40.45° C.), P. 150, R. 32. The patient was now beginning to be restless, but no effort at restraint was made.

Sept. 11.—4 a.m.: He was obviously beginning to regain consciousness. Those present in the room were his wife, a nurse, and the house-surgeon. He remained quiet and soon recognized these persons by their voices. He was apparently blind, but after three hours recovered sufficiently to recognize objects in the room. From this time he was very co-operative and began to take fluids by mouth. During the period of narcosis he was catheterized repeatedly, and he found some difficulty in passing urine during the next 12 hours. 10 a.m.: Complaining of severe abdominal pain. Morphine 1/2 gr. (32 mg.) and atropine 1/100 gr. were administered without effect. 12.15 p.m.: Pain continuing. Nephentle 10 m. (0.6 ml.) and tincture of belladonna 10 m. given by mouth. Some nausea but no vomiting. 2 p.m.: Tincture of belladonna 10 m.; pain easier. This was repeated at 5 p.m. 11 p.m.: Patient unable to sleep; abdominal pain very severe. Morphine 1/2 gr. given; repeated at 1 a.m.

Sept. 12.—3 a.m.: Again very violent and "light-headed." Sleep was induced as before with 0.5 g. of pentothal; he slept for 3½ hours after this. On wakening the patient felt much better. The pain had subsided and his eyesight had recovered. He was very weak, and fell into a deep sleep. From then onwards he continued to improve rapidly. There was no internal or external haemorrhage, and the abdominal wound held firm except for two skin sutures.

It is interesting to note that he remembers nothing from the time when he went into theatre on Sept. 7 until he regained consciousness on Sept. 11. He does remember vaguely the vomiting of blood on the afternoon of the 8th.

COMMENT

With a history of previous post-operative violence, and in view of the recent psychological history, it was feared that the patient might behave as he had done before. The much greater degree of mental disturbance on this occasion may be due either to the greater weight of worry and misfortune or to the longer time he was under the anaesthetic. The exact

exciting factor is still in doubt, since further prolonged narcosis seemed to cure the condition.

It would appear that very dilute intravenous sodium pentothal can be administered over long periods, by means of a saline-drip apparatus, without undesirable after-effects. It is a matter for debate whether the pentothal (7.5 g. at intervals during 31 days) was the cause of the apparent transient blindness, whether it was due to the cumulative effect of the drugs which were given, or whether it was of a hysterical nature.

I wish to express my thanks to Mr. Dalziel for permission to publish these notes; to Dr. Bakeron (the anaesthetist); and to the visitors and resident staff for much valuable advice and assistance in the conduct of this case.

A. ROBERTSON KERR, M.B., Ch.B.,
House-surgeon, Western Infirmary, Glasgow.

Proteus vulgaris Septicaemia treated with Penicillin

Proteus infections of the blood stream are of uncommon occurrence; the report of a case successfully treated with penicillin may therefore prove of interest.

CASE REPORT

The patient, a diabetic woman aged 57, was admitted to King's College Hospital under the care of Dr. R. D. Lawrence for the treatment of varicose veins. The left internal saphenous vein was ligatured by Mr. A. J. Heriot on Oct. 17, 1945, and three days later 3 ml. of sodium morrhuate was injected. A small abscess developed over the site of the injection. This later discharged, and a pure growth of *P. vulgaris* was obtained from the pus on Oct. 25. The leg remained painful and swollen, and for the next three weeks there was an irregular type of fever between 98 and 101° F. (36.7 and 38.3° C.). During this period the patient was treated with 40 g. of sulphathiazole for eight days and an 18-day course of penicillin by 3-hourly intramuscular injections of 20,000 units, but without any improvement.

On Nov. 18 the patient became considerably worse, with a swinging temperature reaching 104° F. (40° C.) and with rigors. The blood was cultured on the same day, and *P. vulgaris* was grown in each of the bottles of glucose broth employed. The penicillin sensitivity of the organism originally isolated from the wound was not investigated, but the strain grown from the blood was inhibited by 3 units of penicillin per ml. (tube-titration method). A daily dose of 640,000 units of penicillin in 3-hourly injections was then started. Unfortunately no estimation of the amount of penicillin in the blood was made at this time, but as no clinical improvement occurred after six days the dose was increased on Nov. 27 to 1.76 million units daily. This was given in 2-hourly injections of 160,000 units each, omitting one dose in the night. The patient's general condition at once started to improve and the leg also became less swollen and painful. Her temperature began to fall steadily, reaching normal after nine days, and there was also a progressive fall in the total leucocyte count. Blood cultures taken on Nov. 28 and Dec. 3 were sterile. The large dose of 1.76 million units daily was maintained for 12 days, and examinations of the blood during this time showed that the penicillin content did not fall below 3 units per ml. There was no relapse when treatment was discontinued, and the patient made an uninterrupted recovery.

COMMENT

Organisms of the *Proteus* group are not infrequently associated with pathogenic lesions. They occur most commonly as secondary invaders in wounds and in infections of the urinary tract and of the ear, but they rarely invade the blood stream. When they do so the mortality rate is high, particularly in non-urinary infections. In a review of the literature dealing with such cases McKee (1944) found that septicaemia was most often associated with otitis media and mastoiditis, with cerebral abscess, lateral sinus thrombosis, and meningitis as common complications. Out of 23 reported cases of *Proteus* septicaemia following non-urinary infections only 5 recovered. Mackenzie and Hawthorne (1933) collected 17 cases of septicaemia following *Proteus* infection of the urinary tract and added one of their own; 5 of them proved fatal. Many of the cases gave a previous history of instrumentation or operation (Wallace and Dudgeon, 1915).

In the present case infection presumably occurred when the vein was injected, though this was done in the operating theatre with proper aseptic precautions and a fresh ampoule of sodium morrhuate was used. The chief point of interest, however, lies in the success which resulted when the dosage of penicillin was correlated with the bacteriological findings. In conclusion, it should be stated that to persevere with such frequent injections over a period of 12 days required no small fortitude on the part of the patient.

G. T. COOK, M.D.,
Asst. Clinical Pathologist, King's College Hospital.

Reviews

RADIOGRAPHY OF GASTRO-INTESTINAL DISEASE

Roentgen Diagnosis of Diseases of the Gastro-intestinal Tract. By John T. Farrell, Jun., M.D. (Pp. 271; illustrated. \$5.50 or 30s.) Springfield: Charles C. Thomas; London: Baillière, Tindall and Cox. 1946.

This book is based on lecture notes used by the author and distributed to his students in radiology at the Graduate School of Medicine of the University of Pennsylvania. It consists of concise descriptions of the radiological appearances associated with diseases of the gastro-intestinal tract and of the radiographic technique used, with 190 illustrative photographs. The subject-matter is arranged rigidly in accordance with the Standard Nomenclature of Disease, but the results of this attempt at precision are unfortunate. Closely related conditions, which would normally be discussed together, are thereby artificially separated, with inevitable duplication of description; for example, Colitis, Chronic; Sigmoiditis; Chronic Colitis due to Poison; Mucous Colitis; Ulcerative Colitis, Left-sided or Universal; and Ulcerative Colitis, Right-sided or Regional, all appear under separate headings on different pages, and many similar examples could be given. Much space is taken up with long lists of uncommon pathological conditions, which are either grouped together in the subsequent text or are not discussed at all; and the eye of the reader is constantly confused by rapidly alternating changes in the printing type used.

The book contains much useful information, but it is difficult to imagine what kind of reader the author had in mind when he decided to have these notes published in book form. Graduate students of radiology, wishing to revise this branch of the subject before an examination, might well find this manual helpful; practising radiologists, however, would find little that is not already available in the larger standard textbooks; while physicians, surgeons, or general practitioners, who might be expected to welcome a book of this kind, would be continually irritated by the defects in arrangement of the text to which allusion has already been made; they might read it with profit, but scarcely with pleasure.

GENITO-URINARY DISEASES

Synopsis of Genito-urinary Diseases. By Austin I. Dodson, M.D. Fourth edition. (Pp. 311; illustrated. 16s.) London: Henry Kimpton.
Urological Diseases. By David M. Davis, M.D., Professor of Urology, Jefferson Medical College. Fourth edition. (Pp. 212; illustrated. 12s.) London and Philadelphia: W. B. Saunders Company.

In spite of the recent war genito-urinary surgery has advanced, and improvements in treatments have made necessary the appearance of a new edition of Dr. Dodson's well-known book. In it the uses and the limitations of the sulphonamides and of penicillin in the treatment of urinary infections are discussed. In Chapter XII attention is drawn to the value of castration and of oestrogen therapy in the palliative treatment of carcinoma of the prostate. The illustrations have been improved by substituting original pyelograms for the diagrams appearing in previous editions. As medicine advances, becomes more complicated, and divides itself into more and more special departments, synopses become of greater and greater value. Dr. Dodson's book will be of great service to those who because of the war have been unable to keep in touch with advances in urology and who now wish to revise their knowledge of this subject. It is perhaps unfortunate that the cost of such a useful handbook as this should be as high as it is.

The nursing of a genito-urinary case is of the utmost importance; it would be no exaggeration to say that the after-treatment of a case of prostatectomy is as important as the operation itself. This being so, a urological primer written for nurses should be of great value. The fourth edition of Dr. Davis's book has been carefully revised so as to include such advances in medicine as the use of the sulphonamides and penicillin and the new method of treating carcinoma of the prostate by oestrogens and castration. The subject-matter falls naturally into two parts: the nursing care of urological cases, and the maintenance and the sterilization of urological equipment. These matters are clearly and simply described and the descriptions are supplemented by excellent illustrations. Dr. Davis's book can be recommended to all nurses who wish to revise their knowledge of this branch of their profession.

SURGICAL TREATMENT OF OSTEOARTHRITIS OF THE HIP

Traitement Chirurgical de l'Arthrite Sèche de la Hanche. Suivi de Travaux de la Clinique Orthopédique de la Faculté de Lyon. By L. Tavernier and Ch. Godinot. (Pp. 360; 103 figures. 150 francs.) Paris: Masson et Cie. 1945.

This book comprises a series of papers of wide scope by Prof. Tavernier and his associates at Lyons. In the first and largest section, dealing with osteoarthritis of the hip, an analysis is given of 100 cases treated by operation. The earlier cases were treated by arthrodesis. Later on emphasis has been upon arthroplasty. More recently still, various forms of sensory denervation have been carried out, and this, the authors consider, should be a routine procedure for the more distressing forms of osteoarthritis, no matter what else is done. Intra-articular operations have certain special indications: arthrodesis for unilateral cases. Arthroplasty, which should be "ideal," nevertheless is of dubious value because the results so frequently fall short of what one hopes for. Prof. Tavernier, however, advises it in bilateral cases, for, though no operation gives uniformly successful results, one procedure does not exclude the other if the first fails. The grossness of the disability caused by the disease and the inadequacy of medical treatment fully justify the surgical approach, in view of the enormous benefit that so often can be derived. Most British orthopaedic surgeons would fully support this view.

The second part of the book deals with osteoarthritis of other joints, and the third part comprises 14 papers reflecting the wide interests of the Lyons orthopaedic school.

INDIVIDUAL GYMNASTICS

Individual Gymnastics. A Handbook of Corrective and Remedial Gymnastics. By Lillian Curtis Drew. Fifth edition, revised and edited by Hazel L. Kinzley. (Pp. 253; illustrated. 15s.) London: Henry Kimpton. 1945.

It is now nearly a quarter of a century since the late Miss Lillian C. Drew first produced her book on *Individual Gymnastics*, and the present review concerns the fifth edition, revised by Miss Hazel L. Kinzley. This means that there has been over all these years a steady demand for instruction in this sphere of rehabilitation. The time has, however, passed for loose unscientific statements in any subject connected with medicine to be tolerated with the patience of twenty-five years ago. This is an age of science and of a deep appreciation of physics and physical facts in our daily life. Again, there are parts of this book that seem strangely out of tune with the lessons learned in the last war of the value of class games and exercises, as practised at the various rehabilitation centres such as Loughborough for the R.A.F. and Kingston for the Army. In this country passive movements in the treatment of fractures have been condemned for many years, so strongly that for time physiotherapists were only allowed to handle orthopaedic cases provided passive movements were never employed, but on page 117 "passive movements to restore the normal range of movement . . . are of great assistance" in fractures.

About a quarter of the book is taken up with a number of exercises well illustrated and carefully defined. Each exercise is annotated under the subdivisions "starting position," "movement," "variation," "comment," and "value." It is unfortunate that in neither preface, foreword, nor the opening chapters is any indication given of the audience for whom the book is written. It would be far too elementary for the fully trained physical training instructor or qualified gymnast in this country; it would, equally, be of little real value to medical practitioners or student physiotherapists. Hence it is difficult to conceive the group which would find real value in a book that has had so much care and time spent on its revision.

Notes on Books

We wonder into whose pocket the second edition of *A Pocket Surgery*, by PHILIP H. MITCHNER and A. HEDLEY WHYTE, will find its way. The terse phrasing and direction as to the outstanding points in diagnosis and treatment may during the war years have been valuable to the general service medical officer, called to do duty on the surgical side of a hospital or elsewhere and whose tunic pocket the book probably filled. It may be supposed that it will now slip into the pocket of the pre-examination student, but woe betide him if he is not well versed in the surgical practice of his

hospital, because brevity has here reached dangerous lengths. For example, chronic appendicitis, he is told (p. 219), produces tiredness, weakness, indigestion, and epigastric pain chiefly, but in no way definitely related to meals . . . "all symptoms completely clear up when the appendix is removed." It is to be hoped that those who buy this little volume will not keep it too frequently in pockets from which absorption is slow, because there is in it much worthy of assimilation. The publishers are J. and A. Churchill, and the price is 8s. 6d.

Several recent incidents have focused public attention on the punishment of troublesome boys and young men in Borstal establishments and in civil and military prisons. In *Eliminating Punishment* (Psychological and Social Series, 10, Nottingham Place, London, W.1; 1s.) Mr. W. DAVID WILLS makes out a convincing case for doing away with punishment altogether in reformatory treatment of this class of citizen. He writes from long practical experience, especially at Hawkspur Camp and Barns House, two hostels started by the Society of Friends during the war which received lads and men of very varied and difficult types. He maintains that discipline as commonly understood has no value in the training of character, that the discipline that is necessary for the administration of a community can be achieved without punishment, and that punishment is unconditionally wrong because it defeats the aim of character training. How these difficult young males can be turned into useful and creative members of a community and of society by making them share the responsibility for its life, and how the search for ways to defy authority which obsesses so many of them can be diverted into a more useful channel, make a fascinating story, which is illustrated by extracts from many records.

Principles of Internal Medicine: A Course for Nurses, by Dr. D. M. BALTZAN (Toronto: The Ryerson Press), is available in London from Hatchards, Ltd., at 25s. This book illustrates a tendency which we frankly regard with apprehension; that is, that there shall be an approximation of a nurse's training to that of a medical student. Many syllabuses of the nurse's curriculum illustrate this tendency. The result is either a façade of unassimilated knowledge or a diversion of the nurse's attention from nursing. The author has produced an elaborate book, full of information; but in the first chapter he devotes a section to the principles of diagnosis, which, we submit, does not come into the nurse's province. Yet we have failed to find any information about what a nurse should observe and report to the doctor, or any guidance in, what is surely fundamental, the care and comfort of the patient. Dr. Baltzan has lectured at various training schools for nurses, so that it is possible he has been the victim of a bad system. In any case, it is high time that a protest was raised against a system which evokes such a misconception of the proper training of a nurse.

More Thoughts and Comments of a Doctor, II-VII, by Dr. F. PARKES WEBER, is published by H. K. Lewis at 2s. 6d. The breadth and depth of Dr. Parkes Weber's learning, both in medicine and in archaeology, continue to surprise even his oldest friends. In this little collection of papers he ranges from the Sturge-Weber panathenaic amphora to contemporary forgeries of money. His own interest in these somewhat obscure topics carries the reader with him.

Preparations and Appliances

R.A.F. FLYING OVERALL

The R.A.F. "flying overall," which saved the lives of many men suddenly precipitated into the cold sea, is described by Squadron Leader E. A. Pask, M.B., in the May number of the *Maker-up* (the trade journal for clothing manufacturers, published from 110, Fleet Street, E.C.4). The overall, which is put on before flying, can be worn for any length of time because, although it is waterproof, perspiration escapes through the fabric. Its invention is the outcome of the combined efforts of the scientists of the R.A.F. Institute of Aviation Medicine and the Cotton Research Association, with the help of British spinners, weavers, and cloth processors. It is made of a special "Oxford weave" cloth with "tropical" interlining. A five-ounce (142 g.) interlining supports a 12-stone (76-kilo) man in water and retains its buoyancy almost indefinitely. It insulates the body against heat and cold, and so protected our bomber crews against extreme cold. Paradoxically it kept fighter pilots cool in the heat of the cockpit. The materials from which the R.A.F. flying overall is made will be available for civilian clothes and may revolutionize the manufacture of waterproof and other garments.

In order to cope with post-war difficulties in the production of surgical instruments and aseptic hospital furniture, Down Bros. and Mayer & Phelps have amalgamated. The personal managements remain as heretofore.

LONDON

SATURDAY JUNE 22 1946

CHEMISTRY AND MEDICINE

The relationship of chemistry to medicine has been discussed often and from many standpoints. Historically, the association of these two branches of knowledge has passed through great vicissitudes. At the one extreme we have the school of the iatro-chemists of Leyden in the seventeenth century, who founded their whole philosophy of medicine upon chemistry; at the other, we have the attitude of scepticism and even resentment of chemists, which seems to have grown up on the part of physicians in parallel with the great advances of clinical medicine during the nineteenth century. Now we have reached a stage at which sympathy and co-operation between chemists and medical men have again become closer, and at which few of the latter would belittle the debt their profession owes to chemical science. There can be no question that the continuance and increase in the activity of the interaction between chemistry and medicine will be to the benefit of both: if this is to be achieved, however, it is necessary that more than lip service should be paid to the principle by the members of both professions. The chemist must look upon medical problems as offering a field for the fullest possible development of his own science, and the medical man must learn to see in chemistry more than a source of new drugs and new laboratory techniques. How far can we say that these requirements are now being fulfilled?

It is probable that the neglectful attitude of medicine to chemistry during the last century was first altered by the discovery of the internal secretions, rapidly followed by that of the vitamins. When we add to these achievements of physiology and chemistry the accession of strength to therapeutics which has come with the evolution of chemotherapy there would seem to be little fear that the capacity of chemistry to help medicine would ever again be doubted. Moreover, it must be remembered that these achievements not only were services to medicine but represented advances in chemistry itself; they could not have been made but for the previous accumulation of chemical knowledge, and to the further increase of such knowledge they themselves contributed. An excellent example of this interplay of forces is afforded by the story of the chemistry of penicillin, referred to by the President of the Royal Society in the address on the occasion of the bicentenary celebrations of the Middlesex Hospital, which is printed elsewhere in this issue. The isolation in the pure form of a natural product having the peculiar properties and chemical instability characteristic of penicillin and the later massive industrial production of this substance are triumphs of the application of the principles of chemistry and the technique of chemical engineering to a microbiological problem. In the successful unravelling of the chemical

constitution of penicillin we see the methods of classical organic chemistry at work, with essential support from physics in the form of x-ray crystallography. On the other hand, the failure up to date to achieve a practicable synthesis of penicillin, in spite of the resources of chemical talent which have been brought to bear on the problem, reveals the incompleteness of organic chemical knowledge which Sir Robert Robinson is at pains to point out. It is not to be supposed that the attack on the problem of the synthesis of penicillin will be abandoned, and it is more than likely that success, when it comes, will bring in its train important new accessions to the science of organic chemistry. Here, then, is a case where chemistry has been able to help medicine by bringing a microbiological discovery into the practical service of therapeutics, and where the very failure of the chemists to solve the complete problem will stimulate them to make further efforts to develop their own science.

There are, however, less obvious ways than the synthesis of a new therapeutic agent or even the elucidation of the chemistry of a hormone or vitamin in which chemistry may help the development of medicine, and to these Sir Robert Robinson rightly calls attention. These ways are less obvious because they concern the fundamental chemistry of proteins and of the cell—questions which may seem as remote from practical medicine as did the researches of the nuclear physicists from the reality of Hiroshima. With the recent history of atomic research in mind, he would be a bold man who would question the practical potentialities of the most academic biochemical research; the exploration of the structural chemistry of proteins in general and the particular study of nucleoproteins are growing points in chemical investigation from which may be expected advances having not only a profound effect on biological thought but practical results in medicine itself.

The account which Sir Robert Robinson has given of the past contributions of organic chemistry to medicine is sufficient to show that there is no unwillingness on the part of the chemist to choose the field offered by medical problems for the pursuit of his own branch of science. A chemist who makes this choice can, by diligence in study and by cultivating scientific contacts with biologists and medical men, go some way towards achieving a real understanding of the biological aspects of the problem he is studying. If he is to play his part to the best effect, however, he must be met by genuine collaboration from the medical side, and this can be given only if the medical man will make a corresponding effort to understand the background and mode of thought of the chemist sufficiently to appreciate both the ways in which he can help and his limitations. Appreciation of the potential usefulness of chemistry to medicine is not enough; nor is it enough for the medical man to pose problems to the chemist and to trust to the technique of the latter to do the rest. Rather is there needed sympathetic and understanding discussion in which problems not only are posed but are so far analysed that the chemist is placed in the best position to plan a feasible attack on the essential points. It is clear that fruitful discussion of this sort cannot take place unless the medical man has a real and

understanding appreciation of the past achievements and the potentialities of chemistry in its application to biology. Such appreciation can come only from the instruction in chemistry and biochemistry which is given to medical students, and Sir Robert Robinson has done a useful service in calling attention once more to the great need for improvements in this respect. So long as the medical student, as is now often the case, can complete his course with little appreciation of chemistry as a science, and having acquired perhaps an active distaste for it as a technique, he will be quite unable later on to collaborate with a chemist to the mutual advancement of chemistry and medicine. He may, as a doctor, value the practical results of the chemist's work and he may even admire his scientific ability, but he will be incapable of joining with him in intellectual effort directed to a common end. If the ultimate solution of this educational problem is far from clear, it is certain that a considerable advance would be made if more medical men were able to find a vocation in research and teaching in the chemical aspects of their subject. At present such men are all too rare. An increase in their number would do much to bridge the remaining gap between chemists and biologists, not only by virtue of their own work, but through the influence they would exercise on the medical students who passed through their hands.

"MALIGNANT MALNUTRITION"

During the years between the two world wars the science of nutrition developed rapidly. A wealth of new knowledge was gathered, and it seemed probable that the main facts concerning the food principles necessary for sound nutrition, and the ill effects of their omission, had already been elucidated. Thus scurvy resulted from deficiency of vitamin C, xerophthalmia and night blindness from deficiency of vitamin A, hunger oedema from deficiency of protein, and so on. To some workers it appeared that the days of important new discoveries were over, and that future developments would lie in the application of existing knowledge to practical medicine and dietetics.

Theoretical progress has certainly been impressive; no one will deny the urgent need for its full practical application. But in the Tropics and in war-stricken European countries field workers have demonstrated repeatedly that the clinical picture shown by malnourished or starved populations may often differ widely from textbook descriptions. As Stannus¹ has pointed out, unknown or ill-defined deficiency diseases probably far outnumber those whose characteristics are already plainly established. The condition of "malignant malnutrition" recently studied in Uganda by Trowell and Muwazi² presents problems which expose the limitations of existing knowledge. The first adequate description of this disease was given in 1933 by Cicely Williams,³ who used to describe it by the native name of "kwashiorkor," meaning a red boy or man. Although a reddish pallor of the skin and a softening and browning of the hair are frequently seen in affected native

children, the change of colour in adults may be much less noticeable. Other features of the syndrome are loss of weight or failure to grow, oedema, an abnormal albumin-globulin ratio, crazy-pavement dermatosis, macrocytic anaemia, slight mental and neurological changes, and a deficiency bowel pattern, as indicated in the x-ray film. Although food passes through the intestines at a normal rate much undigested material is present in the faeces. The stools are loose, and in children there is steatorrhea. The complete picture, however, is not always shown. The bowels may not be loose, and in children there may be no crazy-pavement dermatosis. In adults there is sometimes moderate osteoporosis. In specimens of liver taken by biopsy Gillman and Gillman⁴ in 1944 found fatty degeneration, which was sometimes preceded by pigment cirrhosis.

An examination of native diets indicated that very poor labourers subsist on inadequate amounts of cassava, which is deficient in most nutrients except vitamin C. Other labourers, who come from Belgian mandated territory to seek work in Uganda, live mainly on sweet potatoes, with a very little meat and green vegetables. Ganda peasants and their children have a slightly more varied diet, with plantains, potatoes, green vegetables, ground nuts, sugar, and a little meat. Even this diet, however, was calculated to be deficient to some extent in protein, calcium, and nicotinic acid, and to a less extent in aneurin, riboflavin, and vitamin A. To complicate the appraisal of the effects of malnutrition many of the natives suffered from malaria, hookworm disease, syphilis, and various protozoal infections. "Malignant malnutrition" is often fatal, and the response to dietary treatment slow and uncertain. The presence of dermatitis might suggest that a form of pellagra is involved, but while treatment with nicotinic acid amide caused a peeling of the dermatosis a glazed and reticulated surface remained which showed no further improvement. Similarly, treatment with aneurin improved the appetite and increased the sense of well-being, but had no effect on the oedema. Liver concentrates and ferrous sulphate were beneficial to those suffering from macrocytic anaemia. Satisfactory cure of the syndrome as a whole, however, was effected only by the combined action of an improved basal diet and supplements of liver, milk, aneurin, and nicotinic acid.

Further research may reveal the lack of some single factor which is mainly responsible for "malignant malnutrition." In view of the high incidence of macrocytic anaemia, the recent work of Spies⁵ suggests that folic acid therapy is at least worth a trial. On the whole, however, it seems most probable that several deficiencies are involved, and that pathological changes are caused in the tissues which are not easily corrected even when the missing nutrients are restored. We are therefore faced with the possibility that a nutritional deficiency disease, with fairly well defined lesions, may be due not to a single dietary defect but to multiple deficiencies. If this is so the ingenuity of the clinician will be taxed in applying the lessons learnt in the experimental study of nutrition to his work in the field.

⁵ *Lancet*, 1946, 1, 225.

intention occurred; on the other hand, if the build-up curve was below normal healing would probably not occur and more radical surgery was necessary. Counts were also taken in these cases at other positions, such as the calf, popliteal region, and the thigh, and comparisons were made between counts made at the same level in the two legs, so that the extent of the disease process might be established. These counts proved particularly useful in determining the site of amputation at which healing might be expected, and often confirmed the present clinical tendency of thinking that in many cases of gangrene needing amputation the knee-joint can be saved.

RACIAL DIFFERENCES IN MORTALITY

The mortality experience of a country is a fair index of its economic and hygienic conditions. Perhaps the best-known specific cause of death that can be correlated with social conditions is tuberculosis. International comparisons show that tuberculosis decreases in importance with increasing industrialization, but within any country industrial areas have a larger death rate than rural districts. It has often been suggested that differences in death rates between countries may be due partly to some racial trait. Widely varying living conditions make it almost impossible to separate environmental and racial causes of differences in mortality. But the large groups of alien origin sharing much the same environment in the United States of America supply data for the study of this problem.

Dublin and Baker,¹ analysing the records of New York and Pennsylvania for 1910, showed that the death rates for the foreign-born population were higher than those for the natives. This classic study was based on 20-year age groups. A similar study covering New York State and New York City has been made recently by Calabresi.² The data used were the deaths for the five years 1928-32 and the census of 1930; the rates were standardized in five-year age groups by the indirect method employed by the Registrar-General of England and Wales. Standardized death rates for New York State over the period studied were 11.8 for native-born males and 10.2 for females, as against 12.9 and 11.4 for foreign-born males and females. Italians had the lowest rates—10.4 for males and 10.7 for females. For people born in England, Scotland, and Wales the corresponding figures were 11.5 and 10.7. Germans (12.6 and 11.0) and Canadians (12.9 and 11.7) had a mortality in excess of the native-born. Russians and Poles had a high mortality, but the Irish had the worst experience with rates of 16.5 and 15.0, which was 40% above that of the native-born population. An examination of the specific causes of death showed that Italians had a high rate for pneumonia; Germans had a low rate for tuberculosis and pneumonia; Canadians had a low rate for tuberculosis. There were also some interesting contrasts between the sexes. Heart diseases and diabetes were more frequent among Italian females than males; British females had an unusually high incidence of cancer; nephritis and diabetes were relatively higher in the native-born females than among males.

The large alien-born element in America must have an important influence on the size of the American death rate. The proportion of the population of Irish origin (Irish Free State) was estimated to be 11.2 of the total population in 1920. The unfavourable death rates of the foreign-born may be due to the persistence of old habits and traditions, which may greatly influence personal hygiene and the general standard of living. However, it does not seem likely that this is an important factor because the Canadians had an adverse experience. Though mainly

of British stock, they had a mortality considerably above the extremely favourable rate shown by the British. A comparison of the mortality of the foreign-born American with that of the country of his origin is not likely to show whether mortality is improved or not by residence in the United States, since the immigrants cannot be taken as representative of their native country. A further study, based on the mortality of the descendants of the foreign-born population, would be necessary before any conclusion could be reached on the vitality of the different races.

MEDICAL PHOTOGRAPHY

A Medical Photographers' Group has now been constituted within the Royal Photographic Society. At its inaugural meeting Surg. Rear-Admiral C. P. G. Wakeley remarked that the medical profession has hitherto had to rely largely for its records upon free-hand artists, and some excellent work has been done, but such service is often not available, and increasing resort has to be made to photography, alike in the operation theatre, the ward, the out-patient department, and the post-mortem room. Given the right technique, no more accurate method exists. Admiral Wakeley spoke of the value of records made before and after treatment, operative or other, and insisted on the need for such pairs of photographs to be on the same scale and to be made so far as possible according to the same procedure. A number of speakers, including photographers attached to large hospitals and free-lance medical photographers, gave an account of their experiences, which suggested that photography now has an importance in many departments which calls for a highly trained expert. Dr. Richardson Billings described a method he has worked out for photography in the operating theatre. A usual method is to have a long-focus lens in the camera and lights fixed above the table, well out of the field of surgical activity. Dr. Billings has employed a different method. From his heavy-based tripod rises a perpendicular standard supporting a baseboard so arranged as to give universal movement and to carry the camera and lamps. The illumination comes from photoflood apparatus mounted in chosen positions around a form of lens hood, with a central incandescent lamp for focusing. The novel feature, however, is a mirror—or it may be a prism—set at an angle of 45° to the optical axis of the camera, the principle being the same as that of the laryngoscope and giving a "surgeon's-eye view" of the field of operation. It is claimed that this eliminates the distortion and foreshortening inevitable with a camera at any other angle or distance. The arrangement also fulfils two necessary conditions: that the photographer and his apparatus must keep out of the way of the surgeon, and that the apparatus must need the bare minimum of preparation. Among experiences related by photographers was the obtaining of a rapid sequence of films to illustrate the delivery of twins by Caesarean section—a task requiring unexpected mobility on the part of the photographer and his apparatus.

THE HALF-YEARLY INDEXES

The half-yearly indexes to Vol. II of the *Journal* and the *Supplement* for 1945 have been printed. They will, however, not be issued with all copies of the *Journal* but only to those readers who ask for them. Any member or subscriber who wishes to have one or both of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Accountant, B.M.A. House, Tavistock Square, London, W.C.1. Those wishing to receive the indexes regularly as published should intimate this.

² *Human Biology*, 1945, 17, 340.

BIRTHDAY HONOURS

The names of the following members of the medical profession were included in a Birthday Honours List published in *Supplements to the London Gazette* on June 13

Barony

St AVROUSE, EDGAR WOODALL, M.D., M.S., F.R.C.S. Senior Surgeon, Manor House Hospital, Golders Green. For political and public services.

K.C.S.I.

Major-General (Jocel Lieutenant-General) GORDON WILSON, C.B., CBE, M.C., M.B., Ch.B., late R.A.M.C. Honorary Surgeon to the King. Director, Medical Services in India.

K.C.M.G.

PETER HENRY BUCK, D.S.O., M.D., D.Sc. Director of Bernice P. Bishop Museum, Honolulu, and Professor of Anthropology, Yale University. For services to science and literature.

K.B.E. (Military Division)

Major-General ALEXANDER GORDON BRIDGMAN, C.B., OBE, MD, F.R.C.P. late R.A.M.C. Honorary Physician to the King.
Brigadier (Local) HUGH WILLIAM BILL CAHNS, F.R.C.S., R.A.M.C. Acting Air Vice-Marshal JOHN JONAS COVATARI, M.C., M.D., F.R.C.P., R.A.F.V.R.

Air Marshal ANDREW GRANT, C.B., CBE, M.B., Ch.B., R.A.F. Temporary Surgeon Rear-Admiral CECIL FLEMING GRAY WATLEY, C.B., D.Sc., F.R.C.S., F.A.C.S., F.R.A.C.S.

K.B.E. (Civil Division)

HARRY CHAPMAN SINDERSON, C.M.G., M.V.O., OBE, MD, F.R.C.P.E. Dean of the Royal Faculty of Medicine, Baghdad.

Knighthood

Major-General GORDON COVILL, C.I.E., MD, I.M.S. Honorary Physician to the King. Director, Malaria Institute of India, Delhi.
ANDREW DAVIDSON, M.D.Glasg., F.R.C.S.Ed., DPH. Honorary Physician to the King. Chief Medical Officer, Department of Health for Scotland.

PHILIP NOEL PANTON, M.B., B.Ch. Consultant Adviser in Pathology, Ministry of Health.

LEONARD GREGORY PARSONS, M.D., F.R.C.P., F.R.CO.G. Professor of Diseases of Children, and Dean of the Faculty of Medicine, University of Birmingham.

C.B. (Military Division)

Major-General NEIL CANTLIE, M.C., M.B., Ch.B., F.R.C.S., late R.A.M.C. Honorary Physician to the King.
Surgeon Vice-Admiral HENRY ST CLAIR COLSON, CBE, M.B., B.S., DPH, R.N.

Major-General (Temp.) JOHN CECIL ALEXANDER DOWSE, C.B., M.C., M.B., B.Ch., late R.A.M.C.

Major-General DAVID VINCENT O'MALLEY, OBE, M.B., B.Ch., I.M.S. Honorary Surgeon to the Viceroy of India.
Air Vice-Marshal ARTHUR EDWARD PANTER, M.R.C.S., L.R.C.P., R.A.F. Honorary Surgeon to the King.

C.S.I.

Major-General JOHN PATRICK HUBAN, OBE, M.B., B.Ch., I.M.S. Honorary Surgeon to the King. Surgeon-General with the Government of Madras.

C.I.E.

Col. NORMAN BRIGGS, M.R.C.S., L.R.C.P., I.M.S. Inspector-General of Civil Hospitals, United Provinces.

Lieut.-Col. GURDIAL SINGH GILL, OBE, M.B., Ch.B., I.M.S. Inspector-General of Prisons, Madras.

Lieut.-Col. (Temporary Col.) DAYA RAM THAPAR, OBE, M.B., Ch.B., I.M.S./I.A.M.C. Commandant, I.A.M.C., Headquarters, Puna.

C.B.E. (Military Division)

Acting Air Commodore EDWARD DEMETRIUS DALZIEL DICKSON, M.B., Ch.B., F.R.C.S.Ed., R.A.F.

Surgeon Rear-Admiral CYRIL VERITY GRIFFITHS, C.B., D.S.O., M.R.C.S., L.R.C.P. Honorary Physician to the King.

Air Commodore PHILIP CLERMONT LIVINGSTON, OBE, A.F.C., F.R.C.S., R.A.F.

Brigadier (Local) JOHN RAWLINGS REES, M.D., F.R.C.P., R.A.M.C. Col. OSWALD LYALL SHEARER, L.R.C.P.&S.Ed., S.A.M.C.

C.B.E. (Civil Division)

LEONARD WYNNE EVANS, M.R.C.S., L.R.C.P., Colonial Medical Service. Chief Medical Officer, Penang, Malaya. For services prior to and during the Japanese occupation.

JAMES FERGUSON, M.B., Ch.B., D.P.H. Lately County Medical Officer of Health, Surrey.

WILLIAM KESLEY FRY, M.C., M.R.C.S., L.R.C.P., I.D.S. Dental Surgeon, Guy's Hospital.

Lieut.-Col. HIRDA MARY LAZARUS, F.R.C.S.Ed. Chief Medical Officer, Women's Medical Service, and Assistant Director-General, I.M.S. (Women's Branch).

OSBORNE HENRY MAYOR, M.D., F.R.F.P.S. Playwright ("James Bridie"). Chairman, Scottish Committee of the Arts Council.

TOM LAKIN PAGET, M.R.C.S., L.R.C.P. Formerly Director of Maternal Welfare, Health Department, New Zealand.

HENRY RICHARD RISHWORTH, OBE, F.R.C.S. Principal Medical and Health Officer, Great Indian Peninsula Railway, Bombay.

DOUGLAS JAMES VALENTINE, M.C., M.B., B.S., Colonial Medical Service. Lately Deputy Director of Medical Services, Hong Kong. For services during internment.

OBE (Military Division)

Acting Wing Cmdr FENTON BRATHWAITE, F.R.C.S., R.A.F.V.R. Col (Temp.) GREGORY WILLIAM STANLEY FOSTER, M.R.C.S., L.R.C.P., R.A.M.C.

Lieut.-Col. HARRY KARL GROFF, V.D., M.D., R.C.A.M.C. Col. HAROLD PARRISH HAMILTON, M.D., R.C.A.M.C.

Lieut.-Col. (Temp.) CHARLES HENRY HOSKIN, M.B., B.Chir., R.A.M.C.

Lieut.-Col. (Temp.) NOWSHIR JUNGALWALLA, M.B., B.S., I.A.M.C. Acting Surg. Capt. GIORGIO MCCOTTELL, V.D., M.D., R.N.V.R.

Col. ROSS HOSMER MCGIBSON, R.C.A.M.C. Lieut.-Col. JAMES CHRISTIE PATTERSON, M.C.P.&S., R.C.A.M.C.

Surg. Cmdr. ARNOLD PERRY, V.D., F.R.C.S.Ed., R.N.Z.N.V.R. Acting Group Capt. PATRICK BRUNTON LEE POTTER, M.D., R.A.F.

Col (Temp.) RONALD WILLIAM RASTIN, F.R.C.S., R.A.M.C. Lieut.-Col. (Temp.) ARCHIBALD MAXWELL ROBERTSON, M.B., Ch.B., R.A.M.C.

Surg. Cmdr. EDWARD GWYNNE THOMAS, V.D., M.D., R.N.V.R. Temp. Acting Surg. Lieut.-Cmdr. DAVID ALEXANDER THOMSON, M.B., Ch.B., R.N.V.R.

Col. (Acting) LARSEN EDWIN VINE, M.B., B.S., F.R.C.S.Ed., R.A.M.C. Malayan Medical Service.

Surg. Cmdr. WILFRED KIRITH WELSH, M.C.P.&S., R.C.N.(R.).

OBE (Civil Division)

RAJNAM APARUDDI, I.M.S.S.A. For service as surgeon, Penang, during the Japanese occupation.

LOI PO CHEN, M.B., B.S. Lately Medical Officer, Medical Department, Hong Kong. For services during the Japanese occupation.

KENNETH HENRY DYKE, M.B., Ch.B. Director of Medical Services, Basutoland.

HAROLD FAIRBAIRN, M.D. Colonial Medical Service. Sleeping Sickness Officer, Tanganyika Territory.

TSE JEN HUI. Medical Officer, Medical Department, Hong Kong. For services during the Japanese occupation.

CAPT. ARTHUR DURNFORD LUFF, M.R.C.S., L.R.C.P., I.M.S. Agency Surgeon, South Waziristan, North-West Frontier Province.

Major MUHAMMAD JAFAR, M.B., B.S., I.M.S. Director of Public Health, Bengal.

BURJOR FRAMJI KHAMBATTA, M.B.E., M.B., B.S. Port Health Officer, Karachi.

MARJORIE JEAN LYON, M.B., B.S., F.R.C.S.Ed., Colonial Medical Service. Medical Officer, Malaya. For services during evacuation and internment.

GOPAL DAS MADHOK, L.R.C.P.&S.Ed., Cachar, Assam.

Major JAMES DUNCAN MURDOCH, M.B., Ch.B.N.Z., F.R.C.S.Ed., I.M.S. Professor of Obstetrics and Gynaecology, Prince of Wales Medical College, Patna, Bihar.

ISAAC LADINO OLUWOLE, M.B., Ch.B. Medical Officer of Health, Lagos Town Council, Nigeria.

Rao Bahadur KIZHAKKE COVILAGAM KUTTY ETTAN RAU, L.R.C.P.&S.Ed. Secretary, Health Survey and Development Committee, and lately Assistant Public Health Commissioner with the Government of India.

WALTER SNEDDON ROBERTSON, M.B., Ch.B. Orthopaedic Surgeon, Wellington Public Hospital, New Zealand.

JAMES PATRICK TAYLOR, M.B., Ch.M. Principal Medical Officer, British North Borneo (Chartered) Company. For services during the Japanese occupation.

ROBERT SCOTT TAYLOR, M.B., Ch.B. Medical Officer of Health, Zanzibar.

GAR HSI THOMAS, M.B.E., M.D. Medical Officer, Medical Department, Hong Kong. For services during enemy occupation.

Major GEORGEY BENION THOMAS, M.Sc., M.B., Ch.B.Shell, F.R.C.S.Ed., I.M.S. Superintendent, Government Hospital for Women and Children, and Professor of Midwifery, Madras Medical College.

ARTHUR STEWART WESTMORLAND, M.R.C.S., L.R.C.P., Colonial Medical Service. Senior Medical Officer, Kingston Public Hospital, Jamaica.

ALFRED ERNEST YOUNG, M.R.C.S., L.R.C.P. Medical Officer, Basutoland.

M.B.E. (Military Division)

Major (Temp.) IAN ALFRED ANDERSON, M.B., Ch.B., R.A.M.C.
Capt. RAFFAELLO WILLIAM BIAGI, M.B., Ch.B., R.A.M.C.
Temporary Surg. Lieut. ALASTAIR KINGSLEY BROWN, M.B., Ch.B., R.N.V.R.

Major (Temp.) DAVID LLOYD GRIFFITHS, M.B., Ch.B., F.R.C.S., R.A.M.C.

Capt. (Temp.) MOTI LAL, I.A.M.C.
Major GUY LATOUR, R.C.A.M.C.
Major (Temp.) DESMOND GRAHAM MCCONNELL, M.B., Ch.B., R.A.M.C.

Major ANGUS RUSSELL MCPHERSON, R.C.A.M.C.
Major WILLIAM HENDRICK MYBURGH, M.R.C.S., L.R.C.P., S.A.M.C.

Capt. CHERUKAT PADMANABHAM NAIR, I.A.M.C.
Major (Temp.) EDWARD HARVEY RATCLIFFE SMITHARD, M.D., R.A.M.C.

Captain HARI CHAND TUGNAIT, I.A.M.C.
Capt. RICHARD IVOR WILLIAMS, M.R.C.S., L.R.C.P., R.A.M.C.

M.B.E. (Civil Division)

RANGACHARI PADMANABHA CHARI, F.R.C.S.Ed. Civil Surgeon, Jubulpore, Central Provinces and Berar.

ALEXANDER FRANCIS RITCHIE CRAWFORD, M.B., Ch.B. A prominent medical practitioner of Invercargill, New Zealand.

Sardar Sahib RAJINDER SINGH GREWAL, F.R.F.P.S., Civil Surgeon, Burma.

Khan Bahadur ABDUL HAMID, M.B., B.S. Assistant Director of Public Health, United Provinces.

Major KUNDAN LAL JETLEY, I.M.S. Retired M.O. i/c the Sikh Regimental Centre.

Rai Bahadur JIRWAN LAL, M.D. Formerly professor, King Edward Medical College, Lahore.

AMRATRAL UJAMSEE SHETH, M.B., B.S. For public services in Kenya.

LADY TATA MEMORIAL TRUST

International Awards for Research in Blood Diseases

The trustees of the Lady Tata Memorial Fund announce that, on the recommendation of the Scientific Advisory Committee, they have agreed, if circumstances permit, to make the following awards for research in blood diseases, with special reference to leukaemia, in the academic year beginning on Oct. 1:

Grants for Expenses and Assistance.—Dr. Jørgen Bichel nmark, for work at Aarhus, Denmark, and in the U.S.A.; Pierre Cazal (France), for work at Montpellier; Dr. Peter Gorer (Great Britain), for work in London; Dr. Maurice uérin (France), for work in Paris; Dr. Werner Jacobson (Great Britain), for work at Cambridge; Dr. Edith Paterson (Great Britain), for work at Manchester; Prof. Edoardo Storti (Italy), for work at Pavia.

Scholarships (Whole-time or Part-time).—Dr. Jal J. Dubash (India, at present in U.S.A.), for work in New York; Dr. Pierre Dustin (Belgium, at present in Great Britain), for work in London and Brussels; Dr. Simon Iversen (Denmark), for work in Copenhagen; Dr. Joseph Japa (Poland, at present in Great Britain), for part-time work at Edinburgh; Dr. Hall Schartum-Hansen (Norway), for work probably at Manchester.

A Ministry of Health Circular (103/46) announces that it has been decided to discontinue the Government Lymph Establishment maintained by the Ministry at Colindale Avenue, N.W., and to arrange for lymph required for public vaccination against smallpox to be produced by the Lister Institute of Preventive Medicine and distributed through the 27 laboratories in England and Wales whose addresses are given in an appendix. The change will take effect from July 1. Before the new arrangements start public vaccinators will receive from the Government Lymph Establishment a supply of revised application forms, which alone should be used on and after that date. If the repeal of the Vaccination Act becomes law under the National Health Service Bill the office of public vaccinator will be abolished, but in that event the same general arrangements will continue for the supply of lymph to all doctors with whom local health authorities arrange to provide free vaccination as contemplated in the Bill.

Nova et Vetera

MYIASIS, "FILLAN," AND "THE MORGELLONS"

Two recent reports (Turner, 1945; McCarthy, 1945) have drawn attention to the occurrence in man of infestation by *Hypoderma* larvae, giving rise to creeping myiasis. Although Brumpt (1927) states that this condition, which he calls *myiase sous-cutanée à tumeurs ambulatoires*, is well known to the country folk in Norway, Ireland, Scotland, and Brittany, it may be of interest to quote the following account taken from *A Description of the Western Islands of Scotland*, by M. Martin, Gent., first published in 1703.

"Allan Macleod being about ten years of age, was taken ill of a pain which moved from one part of his body to another, and where it was felt the skin appeared blue; it came to his toe, thigh, testicles, arms, and head; when the boy was bathed in warm water he found most ease. The hinder part of his head, which was last affected, had a little swelling: and a woman endeavouring to squeeze the humour out of it, by bruising it on each side with her nails, she forced out at the same time a little animal near an inch in length, having a white head sharp pointed, the rest of its body of a red colour, and full of small feet on each side. Animals of this sort have been seen in the head and legs of several persons in the isles, and are distinguished by the name of Fillan."

This case occurred in the Isle of Skye. Elsewhere in the same book Martin gives a shorter description of a case in Harris. In the second instance "a little worm, about half an inch in length, and about the bigness of a goose-quill, having a pointed head, and many little feet on each side," was drawn out of the flesh of a man's cheek.

According to Macleod (1934) Martin Martin was born in Skye c. 1655-60, graduated M.A. at Edinburgh University in 1681, and between 1686 and 1692 acted as "governor" to young MacLeod of Dunvegan. In 1697 he contributed to the Royal Society the first of two papers which formed the groundwork of his volume of 1703. Martin entered the University of Leyden in 1710 and there graduated M.D.; he died in London in 1719.

About 30 years before Martin's account Sir Thomas Browne recorded a curious observation in "A Letter to a Friend":

"Hairs which have most amused me have not been in the face or head, but on the back, and not in Men but Children, as I long ago observed in that endemial Distemper of little Children in Languedock, called the Morgellons, wherein they critically break out with harsh Hairs on their Backs, which takes off the unquiet symptoms of the Disease, and delivers them from Coughs and Convulsions."

Kellett (1935) has reviewed this passage in considerable detail and concluded that the reference is to comedones. This explanation is based on a study of a series of descriptions published between 1544 and the present century. It does not, however, cover the deliverance from coughs, noted by Browne, nor the fact that the "worms" mentioned by certain of the earlier writers quoted by Kellett were "wont to infest the muscles of the arms, calves, and back in young children."

The starting-point for an alternative speculation on the nature of the "morgellons" may be found in the migration of *Hypoderma* larvae through skin to muscles, thence to the viscera, particularly of the thorax, and finally to the subcutaneous tissue of the back. It is accordingly suggested that the passage, "they critically break out with harsh Hairs, etc.," may refer to the subcutaneous localization of such parasites, with the subsidence of irritation of the respiratory tract. An intriguing pendant to this hypothesis is that, as Kellett has pointed out, the word "morgellons," though unique, is almost certainly derived via Provençal forms from *muscula*, a little fly.

Dept. of Bacteriology, King's College,
Newcastle-upon-Tyne.

A. H. EMSLIE-SMITH, M.B.

Reports of Societies

PENICILLIN PRODUCTION

The annual meeting of the Manchester Medical Society was held on May 1, and Prof. D. DOUGAL was elected president for the coming year.

Dr. J. B. M. CORROCK, in an address on "The Story of Penicillin," referred briefly to the British discovery and preparation of penicillin from the mould *Penicillium notatum*, and described the commercial methods of producing penicillin by surface culture. This involved preparing the sterile medium and filling it into 70,000 quart (1.1 litre) bottles daily, with subsequent sterilization. After this the bottles were cooled and spray-inoculated under sterile precautions, each bottle receiving $1\frac{1}{2}$ to $2\frac{1}{2}$ million spores. After incubation at constant temperature and humidity, which were controlled by an air-conditioning plant, the contents of the bottles were separated from the mycelial felt, which was burnt. The culture fluid was clarified and then extracted by suitable solvents at an acid pH or by charcoal adsorption and subsequent elution with aqueous solvents and the extracts concentrated, and the dry sterile calcium or sodium salt of penicillin was freeze-dried after sterile filtration.

The solid penicillin salt thus isolated had a potency value of from 300 to 800 units per mg. It was examined analytically and tested for potency, sterility, toxicity, and the absence of pyrogens. If satisfactory it was issued for use either in ampoules or as sterile tablets for preparing solutions for injection, or else as a dusting powder, often diluted with sulphathiazole, for topical application to wounds. The sterile powder might also be compounded with sterile creams, prepared in the form of tablets for use in oral infections, or suspended in arachis oil or beeswax mixture for intramuscular injection. More recently administration by mouth had shown some promise, the vehicles examined including inorganic buffers, egg white, oily suspensions, and aluminium hydroxide gels. Unhardened gelatin capsules had also been used with success in an attempt to overcome the possible inactivation of penicillin by the acid in the stomach. Rectal administration could not be seriously considered until a method was found of protecting penicillin from the action of the destructive enzyme, penicillinase, produced by the bacteria in the lower bowel.

OPHTHALMOLOGICAL CONGRESS

The annual Congress of the Ophthalmological Society of the United Kingdom was held on May 30 and 31, and June 1, in London at the Royal Society of Medicine. There was a large attendance of members, with a number of distinguished visitors from Europe and the Americas.

The president, Mr. CHARLES GOULDEN, opened the congress and chose for the subject of his presidential address "Johannes Evangelista Purkinje."

Air Commodore P. C. LIVINGSTON and Mr. HAROLD RIDLEY opened a discussion on "Ocular Disturbances Associated with Malnutrition," in which Dr. DEAN SMITH, Dr. B. MARIEN-STRAUSS, and Messrs. T. KEITH LYLE, C. DEE SHAPLAND, R. LINDSEY REA, A. SEYMOUR PHILIPS, W. J. W. FERGUSON, A. H. LOWTHER, A. G. CROSS, J. D. FRASER, and several other members took part. It emerged from the discussion that the malnutrition experienced in the prison camps, more especially of the Far East, had caused definite eye symptoms, of which central or paracentral scotomata were the most important. The factors involved were by no means certain, but the lesions appeared to be due to vitamin imbalance rather than to absolute vitamin deficiency. The influence of tobacco was mentioned only to be discounted in the final consensus of opinion. It was felt that ophthalmology had an important part to play in the study of deficiency diseases, and that knowledge had been much increased by the unfortunate experiences of prisoners in this war.

The Bowman Lecturer of the year was Dr. ARNOLD KNAPP of New York, who read a paper on "Intracapsular Extraction."

In a comprehensive survey of this subject Dr. Knapp disclosed his preference for the intracapsular operation. His description of the advantages and disadvantages of this more difficult type of cataract operation was fair, and he showed that in his hands it held no extra risks.

Annual Dinner

The annual dinner of the Society was held at the Royal College of Surgeons on the invitation of the President and Council of the College. Among the guests were Lord Moran, Mr. Eardley Holland, Sir Wilson Jameson, Mr. P. H. Adams, Mr. H. S. Souttar, and Mr. Hugh F. Powell. Guests from abroad included Prof. H. J. M. Weve (Utrecht), Dr. E. C. Gravenmeyer (Amsterdam), Dr. Mériot de Treigny (Paris), Dr. Léon Coppez (Brussels), Dr. Leon Bauwens and Madame Van Boven (Antwerp), Dr. Jules François (Charleroi), Dr. A. Franceschetti (Geneva), Dr. B. Semadeni (Davos), Madame Noëlle Chome (Lausanne), Dr. W. H. Melanowski (Warsaw), Dr. Miguel Millan (Chile), Dr. H. Gjessing (Drammen, Norway), Dr. Gunnar Von Bahr (Uppsala, Sweden), Sir John Herbert Parsons proposed the health of the guests, and Dr. Arnold Knapp and Air Marshal Andrew Grant replied.

The annual general meeting was held next day and the officers for the ensuing year were elected. The remaining two days were devoted to the reading of clinical papers by members as follows:

Dr. I. C. MICHAELSON: "Traversing Intra-ocular Foreign Bodies with Retinal Detachment." Dr. A. LOWENSTEIN, Dr. I. C. MICHAELSON, and Dr. J. HILL: "Perivasculitis Retinae of the Young (Eales's Disease)." Dr. A. J. BALLANTYNE: "Nerve-fibre Pattern of the Human Retina." Mr. EUGENE WOLFF: "Mucocutaneous Junction of the Lid Margin, and the Distribution of the Tear Fluid." Mr. E. F. FINCHAM: "Recent Developments in Artificial Eyes." Dr. MARY CRIPPS: "Treatment of Traumatic and Inflammatory Lesions by X Rays and Short-wave Diathermy Combined." Mr. V. D. GILL: "Technique of Intracapsular Extraction of Cataract with Retention of Conjunctival Bridge." Dr. C. L. SCHEPERS: "Is Malnutrition the Cause of Tobacco Amblyopia?" Mr. T. W. LETCHWORTH: "Stereoscopic Vision in Monocular Aphakia." Dr. MELANOWSKI (Warsaw): "Pages in the History of Ophthalmology in Poland." Dr. A. SEYMOUR PHILIPS: "Retinal Venous Changes in Diabetes."

The Association for Scientific Photography amalgamated with the Royal Photographic Society on March 1, 1946. The work of the Medical Group of the A.S.P. is to be continued, since no time was lost in forming a similar group after the amalgamation. A Medical Photography Group, to deal with all photographic processes connected with medical science, was formed on April 1, and Surgeon Rear-Admiral Cecil P. G. Wakeley was elected its chairman. Those interested who are already members of the R.P.S. should apply to Mr. E. J. Andrews, hon. secretary, Medical Group; while those who do not belong to the R.P.S. should apply to the hon. secretary, Royal Photographic Society, 16 Princes Gate, London, S.W.7. The entrance fee to the R.P.S. is one guinea, and the annual subscription two guineas; the Medical Group subscription is 5s. per annum.

CHEMICAL RESEARCH EXHIBITION

An exhibition, organized by Imperial Chemical Industries, is open until the end of June at 22, Lower Regent Street, London, to demonstrate some of the recent advances in British chemical research. The exhibition has been mounted most attractively, bringing home to the public in pictures and models and in the fewest possible words the significance of each achievement. In this it has been helped by one of the discoveries—namely, the plastic known as "perspex," which is being used not only for prisms and lenses and for surgical and dental equipment, but also for effective display purposes, lending itself as the medium for artistic designs. One section of the exhibition is devoted to the new insecticide "gammexane." This is adorned by a portrait of Michael Faraday, for the origin of this recent introduction was Faraday's preparation of benzene hexachloride more than 120 years ago. It has been long known that this substance had insecticidal properties, but the particular constituent which gave it its destructive nature has only lately been determined. In the form of a smoke pellet it produces a cloud which settles on walls and other surfaces, which are thereupon made lethal to insects alighting upon them, but are not injurious to or animals. It is also effective against the migratory locust on the request of U.N.R.R.A. ten tons have recently been sent to Sardinia, where crops were threatened by a locust invasion. The exhibition includes sections illustrating the amide drugs as well as penicillin and paludrine.

Correspondence

National Research into Tuberculosis

SIR,—I wish to associate myself whole-heartedly with the plea of Drs. S. M. Hilton and George Luntz (June 1, p. 850) for national research into tuberculosis. May I also add a plea for a nation-wide effort to provide facilities for treatment? The number of cases diagnosed is increasing, but every-day facilities for treatment, never adequate, grow less and less as beds close for lack of nursing and domestic staff. By the time many cases reach a chest hospital or sanatorium the favourable opportunity for treatment has often passed and in all probability the seed of new cases been sown. Cannot something be devised to make the staffing of such institutions attractive, and so form some organization to utilize the service of ex-patients in this way? The present position is tragic.—I am, etc.,

Cranham, Gloucester.

M. A. KIRKMAN.

SIR,—It would appear that before there can be national research into tuberculosis we of the medical profession must first examine our consciences. Surely there must first be set in motion a world-wide campaign against ignorance, prejudice, and the appalling apathy which still undoubtedly exists in regard to the disease. This apathy towards the greatest medico-social problem known is the more startling when one reflects that it exists equally within, as without, the medical profession. Dr. F. Heaf (March 2, p. 327) writes: "One has only to attend a few meetings of the Tuberculosis Association to realize the keenness of its members, the interest which they take in new methods of treatment, and their readiness to assist sufferers from this disability in every possible way." If these words could be written of the medical profession at large there would still be no room for our present complacency. As it is the case are too greatly against the comparatively few enthusiasts have made the eradication of tuberculosis their ideal in That they have not long ago become discouraged is a te to their zeal and steadfastness of purpose.

he disinterested attitude of many doctors may be summed up with a few instances. Take the young practitioner who remarks: "How can one possibly be interested in such a dull and chronic disease?" Take the numbers of newly diagnosed cases of established pulmonary tuberculosis, seen by any T.O. anywhere, whose histories too often open on such lines as, "My doctor has been treating me for bronchitis for the past twelve months." Take the houseman who writes a sparse note to the T.O., saying, "So-and-so is riddled with T.B. and is a menace in any ward." This attitude is defeatism or, even worse, downright lack of interest in a highly important clinical entity. Neither are tuberculosis workers entirely blameless, as witness the numbers of patients one sees with contra-selective collapses and persistently yawning cavities, with continued positive sputum from artificial pneumothoraces which should never have been induced in the first instance but for the satisfaction of meddling physicians and over-anxious patients. Thus is brought into ill repute the best therapeutic measure yet revealed to us, the cure becoming worse than the disease.

The doctor who gives the matter any thought must ask himself why it is that the treatment of tuberculosis has stood still for so many years, while more abstract medicine progresses year by year. The explanation must be apathy towards tuberculosis. It cannot be anything else. Drs. S. M. Hilton and George Luntz (June 1, p. 850), in pointing out the obvious lack of interest in the present correspondence, write: "It is an unhappy reflection on the outlook of the medical profession that it is so ready to dilate on medical minutiae, whereas fundamental issues leave it entirely unmoved." Can it be that the problem of tuberculosis is so fundamental that we fail to see it in a true perspective? If this be so then a change of attitude, of outlook, of approach, a readjustment of our minds to the magnitude and importance of the problem, is half a century overdue. Until we rouse ourselves to wakefulness, shout the dangers of contagion in the public ear, make educational use of the cinema, the microphone, the hoarding, and practise the better those therapeutic measures we already possess, we can hardly expect to set benevolently inclined Governmental consciences on fire with a devouring enthusiasm for national research into tuberculosis.

That national research is an absolute necessity there is no doubt; that it will continue to be so is a certainty—unless and until the profession as a whole awakes from its present complacent lethargy and realizes, once and for all, that tuberculosis is not alone a subject for the tuberculosis officer and the sanatorium authorities but is in

fact a problem of such magnitude that it requires the fully conscious consideration, the sympathy, and the concerted attention of every medical man worthy of the name. When we have gained that unity of consciousness and awareness and have ceased to relegate the problem of tuberculosis to the realms of impossibilities, then international research into tuberculosis will long since have already begun.

The impressions that have prompted this letter have been collected throughout several years of work in chest hospitals, clinics, and sanatoria in various parts of England. Impressions collected in Ireland point to the fact that prevailing conditions there are no better. The general practitioner everywhere, on whom, more than any other, rests the responsibility for early diagnosis, is in fact too often the least interested member of the medical community. In younger practitioners this is hardly surprising when one recalls the medical school curricula that give the subject of tuberculosis an equal place with that of the common cold. Now is the time for a change of heart. Now is the time for interest, alertness, action—for research. Let us be in the correct state of grace and knowledge to receive the chemotherapeutic elixir and to use it intelligently when it arrives. If we don't, the accusing finger of the tuberculous population will for ever be upon us.

In conclusion, Sir, I would make a quotation from one William Lloyd Garrison:

"I am aware that many object to the severity of my language but is there not cause for severity? I will be as harsh as Truth and as uncompromising as Justice. On this subject I do not wish to think, or speak or write, with moderation. No! No! Tell a man whose house is on fire to give a moderate alarm; tell him to moderately rescue his wife from the hands of the ravisher; tell a mother to gradually extricate her babe from the fire into which he has fallen—but urge me not to use moderation in a cause like the present. I am in earnest—I will not equivocate—I will not excuse—I will not retreat a single inch—and I will be heard. The apathy of the people is enough to make every statue leap from its pedestal and hasten the resurrection of the dead."

—I am, etc.,

Dublin.

JOHN ST. P. COWELL.

Blindness in Nigeria

SIR,—It is to be deplored that F. E. Stock, in his article of April 6, 1946, on "Blindness in an Urban Centre in Nigeria," made reference neither to trachoma nor to onchocerciasis. Trachoma is by far the most common cause of blindness in West African Colonies, and onchocerciasis probably causes more blindness than (a) ophthalmia neonatorum, (b) keratomalacia and (c) smallpox put together.

(a) Ophthalmia neonatorum is surprisingly uncommon despite the prevalence of gonorrhoea and the paucity of treatment.

(b) Vitamin A deficiency in natives, exposed all day to the sun and whose diet is rich in red-palm oil, is a rarity.

(c) Corneal lesions are a well-known complication of smallpox occurring in 3% of cases (Monte), but more than 10% of Nigerian have trachoma and more than 50% are infested with onchocerciasis; of whom one-third have ocular lesions (J. G. S.).

—I am, etc.,

Johannesburg.

Migrainous, Ciliary, and Post-traumatic Headaches

SIR,—Dr. Wilfred Harris's paper on migrainous, ciliary, and post-traumatic headaches (May 18, p. 754) is very interesting, but open to severe criticism from at least one point of view.

He talks light-heartedly of the "loss of corneal reflex" after his injections, but surely he must be aware that the correct description would be "complete loss of corneal sensation," with its attendant loss of trophic nerve supply. I have seen so many cases with corneal ulceration, and more or less complete "invalidism," or even blindness, of the eye after interference with the Gasserian ganglion that I have grave doubts if the operation is justifiable. Most of these cases can be kept comfortable only by permanent closure of the lids by tarsorrhaphy.

Does Dr. Harris see his cases and inquire about their eyes six months or a couple of years later? And does he put it to the patient that the cure of his pain will almost certainly involve interference with the functions of the eye? I am all too well aware of the number of people who suffer from

intractable headaches, and of the amount of misery that they suffer—without a great deal of help from their physicians or ophthalmologists—to belittle any effort to find permanent relief, even if it is not really a cure.—I am, etc.,

Plymouth

Cecil B. F. Tivy.

Placement of the Disabled

SIR,—While welcoming the publicity given to the Disabled Persons Act by your leading article (May 25, p. 803) I must call attention to some of the inaccuracies it contained. This is the more important since the successful working of the Act largely depends on the co-operation of doctors, many of whom are still ignorant of the provisions of the Act, and in whose enlightenment the medical journals must play a leading part.

1.—The Ministry of Labour has no power to direct labour to a firm employing less than 2% of disabled persons. All it can do is to take advantage of the obligation which the Act imposes upon employers to find suitable employment for disabled persons. In other words, it is more concerned with finding work than with "directing labour."

2.—The statement that Ministry officials do not regard as disabled persons who are in employment is not true. Any such attitude would be contrary to the Act and quite untenable. The D.R.O.s and the District Advisory Committees have had this made clear to them, and it is to be hoped that doctors also will realize that a man who is able to do his present work successfully is not debarred from admission to the register. Some half a million people have been registered, and the vast majority are in employment; 95% of the applications have been accepted by the D.R.O.s direct, and of the 5% referred to committees, 2% have been accepted. These figures surely disprove the statement that D.R.O.s have little responsibility. What is true is that they have no power to compel the disabled person to come to them or to act on their advice, and surely no one would wish them to have this power.

3.—While the figures given as to the distribution of disabilities found in disabled persons may or may not be true, it is, however, known (*Ministry of Labour Gazette*, April, 1946) that the distribution of the disabilities of disabled persons who have registered is as follows: surgical 50%; medical 30%; psychiatric 5%; others (blind, deaf, etc.) 15%.

4.—It has always been obvious that the D.R.O.s would need informed medical help, and steps have been taken to see that this is forthcoming. Moreover, in order that this medical guidance may improve in quality, a follow-up of placed persons has been arranged. It must be remembered, however, that the final word concerning employment rests with the employer, whose co-operation is vital to the success of the Act.

The suggestion that the Ministry of Labour does not exchange information with hospitals and doctors is not true. This is done after obtaining the applicant's consent. It is, however, noteworthy that the British Medical Association, by refusing the use of the medical report D.P.1, which is needed for successful placing, is hindering the very object which the article purports to seek.—I am, etc.,

RONALD E. LANE.

Member of the National Advisory Council
on the Disabled Persons (Employment) Act.

Manchester.

** The B.M.A. has never advised individual doctors or hospitals to refuse to use D.P.1, though it does not approve this form of report. It does not consider that this complicated form can provide the "informed medical help" referred to in 4 and has consistently urged that medical boards should be set up to report on disabled persons in hospital and to advise D.R.O.s on the medical issues involved.—ED., *B.M.J.*

Paralysis Agitans and Cervical Sympathectomy

SIR. The reply in "Any Questions?" on the treatment of paralysis agitans (May 18, p. 784) and also the letters about Parkinson's disease stimulate me to report the result of treatment of these patients by cervical sympathectomy.

I have operated on seven patients (three men and four women) with paralysis agitans or post-encephalitic Parkinsonian tremor; three were diagnosed as cases of post-encephalitic tremor and four as Parkinson's disease. All the patients operated on had been diagnosed and treated at one or several of the hospitals for nervous diseases in London. They were unrelieved and had found their way to that backwater of medicine, the massage department, where my orthopaedic colleague, Mr. Phillip Cutner, suggested the procedure of cervical sympathectomy. The patient in the first case was much better and was able to start

work again. Consequently the operation was offered to other sufferers.

The procedure consisted in the removal of the stellate and first and second dorsal sympathetic ganglia, on the opposite side to the limb most affected by the tremor. When both limbs were affected, then a bilateral cervical sympathectomy was performed at separate sessions on three occasions. The rationale of the operation is to increase the blood supply of the brain.

The results are as follows: There have been no deaths. Four patients are much better (two men and two women); three are unchanged. Those who are improved were aged 33, 35, 36, and 45; those who are unchanged were aged 38, 45, and 68. No patient is worse for the operation. Three of the procedures were performed in 1942, one in 1943, one in 1944, one in 1945, and one in February, 1946. In those improved the tremor is lessened and controlled by medicine, whereas formerly it was uncontrollable. In one woman the tremor was so violent that when she folded her arms during the consultation to try and steady them the body and chair on which she sat shook freely. Resumption of some work has been possible. One woman volunteered that she could write again; another that she could sweep up and dust, previously impossible. The patients are brighter in personality and the mask face and eyes are improved; also the headaches. They still require medicine, but before operation they were unhelped by it.

This short series suggests that the operation of cervical sympathectomy is useful to patients under 45 with paralysis agitans or post-encephalitic Parkinsonian tremor. I report them in the hope that the remedy may be offered to others who are often otherwise derelicts.—I am, etc.,

London, W.1.

HAROLD DODD.

Penicillin and Venereal Diseases

SIR,—Dr. H. W. Neville Mascal's letter (May 25, p. 813) was a timely warning against the indiscriminate use of penicillin, its possible influence on the diagnosis of syphilis, and the production of "fastness," but I would like to add my comments on another aspect of the problem which affords me little cause for complacency on the occasion of the general release of penicillin.

Several years ago I wrote about the abuse of the sulphonamide compounds in the treatment of gonorrhoea. The practice then of patients being referred to clinics with the history of having been treated for a genital discharge with sulphonamides, often in inadequate dosage, without any efforts having been made to ascertain the site or aetiology of the discharge, is still unfortunately quite common. The apparent simplicity and rapidity of penicillin treatment have made a wide appeal, and I fear that it may lead to an increased scope of activity of this unscientific procedure to include suspected syphilitic sores, without preliminary recourse to diagnostic measures.

May I therefore express the hope that practitioners who encounter patients suspect of being affected with venereal disease will either (a) refer them direct to a clinic, or (b) establish a definite diagnosis and ascertain the best therapeutic methods and methods of testing for cure prior to the institution of any "shot in the dark" technique. Failure to do so can only result in an increase in the numbers of undiagnosed, misdiagnosed, and uncured cases, and there are already plenty of these without further contributions.

Much has been learned about the treatment of venereal diseases with penicillin, but still a great deal remains unknown, and it is no secret to state that specialists are still undecided about the exact place of penicillin in the management of syphilis, and opinions are also divided in regard to the best method of administration in the treatment of gonorrhoea.—I am, etc.,

County Hospital, Durham.

W. GILLIES, ANNAN.

Rectal Cancer in Sisters

SIR,—The magisterial rebuke administered by Mr. P. J. Hilton and Dr. S. M. Hilton (May 25, p. 814) to Dr. R. E. Rewell reminds me of Bacon's essay, "Of Seeming Wise." Perhaps that is why Dr. Rewell did not comment upon it. The probability that a random sample of order of magnitude 20 to 30 extracted from a "population" of 300,000 women between the ages of 25 to 35 would contain one or more pairs of sisters is, on any

reasonable hypothesis, extremely small. The magisterial critics are quite justified in saying that the probability of other events might be smaller still. I was told many years ago that a zoologist with a large family of daughters christened them with the generic names of Polychaeta, which are pleasant names—Nereis, Aphrodite, Eunice, etc. It is not likely to be a common practice, and the probability that the sample would contain two young women each named Nereis might very well be much smaller than the probability of including two sisters. But probabilities, like other measures, are great or small in relation to other probabilities. An addition to or subtraction from the annual income of, say, an emeritus professor, of £50 means much more to him than the same change in the national income means to Dr. Dalton. When an event occurs which on some hypothesis, say that of "chance," is very rare, any sensible person asks himself whether there is a reasonable alternative explanation. Dr. Rewell, like a sensible man, has entertained the alternative hypothesis—that the events were *not* independent, that there *might* be a genetic correlation. He did *not* say that correlation had been proved. If the rare event had been the appearance of two persons named Nereis, as the *a priori* probability that having a particular Christian name predisposes a person to die of cancer is extremely small, no sensible person would entertain the alternative. He would simply conclude that a very improbable event had happened—as improbable events do happen every day; in fact every time four people sit down to play a hand at bridge.—I am, etc.,

MAJOR GREENWOOD.

Animal Physiology

SIR,—Our attention has recently been drawn to a review of our book, *The Physiology of Farm Animals*, which appeared in your issue dated May 4. The reviewer calls attention to certain so-called "factual errors," 32 of which he claims to have listed, and later advises students desiring reliable information on the physiology of domestic animals to read the late Sir Frederick Smith's *Manual of Veterinary Physiology*. Of the so-called factual errors quoted by the reviewer, two—namely, that referring to the grazing horse and that referring to the cure of the swollen legs by moderate exercise—are included in the textbook to which he directs students' attention; and since he states that he is not aware "that horses whose legs become swollen or oedematous through much standing may often be cured by moderate exercise" we are left in considerable doubt as to whether the reviewer has carefully read the book he so warmly recommends. The description of the tuberculin test given in our book (p. 144) is correct and was not intended to be a description of the double intradermal test to which the reviewer is probably referring when making his criticism. In criticizing us for giving a range of temperature in the case of the hen, the reviewer is probably unaware that such a wide range exists; incidentally, the alleged correct temperature quoted—104.5° F.—is that of the body hen and not the non-sitting hen, whose average mean temperature is 106.7° F. Moreover, the other so-called errors cited express differences of opinion and cannot be characterized as actual errors.

Finally, we would call attention to the fact that the book recommended as an alternative to ours, excellent though it may have been at the time of publication, is now quite out of date, particularly in the sections relating to endocrinology, vitamins, and the physiology of reproduction.

We apologize for troubling you with this letter, but thought it only right to inform you that the review itself contains errors and is scarcely helpful.—We are, etc.,

F. H. A. MARSHALL.
E. T. HALNAN.

School of Agriculture, Cambridge.

Shock Treatment of Bronchial Asthma

SIR,—I am much interested in Dr. E. Brauer's letter (June 1, p. 849) on the "pyrifer" treatment of asthma. The method he advocates is certainly heroic when one considers how asthmatics have a nasty and unexpected way—at times—of reacting severely to any foreign protein, especially if injected intravenously.

I have practised for some years now the non-specific protein treatment (using Koch's old tuberculin, and more recently P.P.D.), and although my series of cases is as yet too small for definite conclusions to be drawn, the results so far obtained

seem to agree with those of Maxwell (*Journal*, 1930, 1, 854) and others. Complete disappearance of the attacks can be obtained in over 30% of the cases treated. My final doses (as much as 0.5 ml. of the old tuberculin) are generally higher than those recommended by Maxwell and others. In the more refractory cases possibly an optimum maintenance dose at one to three months' interval might be advisable. But if one could feel entirely satisfied that the method suggested by your correspondent was really free from the possibility of dangerous reactions, a real advance in the treatment of asthma will have been made.—I am, etc.,

KINGUSSIE.

FELIX SAVY.

Congenital Malaria

SIR,—Since the publication of the paper on this subject (March 23, p. 432) I have had a report from Prof. Eckstein of three more cases that he had seen in his clinic at Ankara during the month of January, 1946. At that time the mean temperature was below 0° C. Under such conditions in Turkey all surviving anopheles are hibernating and do not bite. The mother of one of these babies was for some time in hospital under treatment for osteomalacia. For years she had suffered from untreated malaria. Her labour started with an attack of fever and she was delivered by Caesarean section. After birth the baby developed pyrexia. Its blood was negative on the first examination but positive on the second.

Dr. R. F. Jarrett (April 27, p. 662) has himself seen cases of congenital malaria during his stay in Turkey. In his bibliography he refers to the case which occurred in London and was reported by Tanner and Hewlett (*Lancet*, 1935, 2, 369). Sir Philip Manson-Bahr was called in consultation to this. They suggested that in the absence of a known placental trauma or infarct, premature placental separation was the most probable cause of the transmission of the infection.

Since my return from abroad I have had access to further literature. K. T. Chen *et al.* (*Chinese Medical Journal*, 1944, 62, 190) have collected 39 cases of congenital malaria from the world literature. In some of these the infant's blood was positive on the first day after birth. The case they reported was that of a baby born in mid-winter in Chungking. Wickramasuriya (*J. Obstet. Gynaec. Brit. Emp.*, 1935, 42, 816) has had an extensive experience in Ceylon and has made a comprehensive study of malaria in pregnancy. He is of the opinion that transplacental foetal infection with malaria occurs more often than is supposed. In his paper he records 6 cases of babies in whom transplacental foetal infection was proved. The infecting parasite was *P. falciparum*. He has demonstrated infecting parasites in fresh foetal brain squash under the microscope without any staining. In these cases he has easily seen living and dead parasites in the cerebral capillaries.

Placental transmission is a subject worthy of further research. The wonder is that the disease is not transmitted to more of the offspring of the millions of pregnant women suffering from malaria.—I am, etc.,

London.

W. C. W. NIXON.

Infantile Paralysis Fellowship

SIR,—May I draw the attention of the medical profession to the Infantile Paralysis Fellowship? Founded in January, 1939, the I.P.F. now has a membership of some seven hundred. We are affiliated to the Central Council for the Care of Cripples, and out of our executive committee of ten, eight are disabled persons. It is one of the few organizations for the disabled run by disabled. With the recent increase of fresh cases—both civilian and Service—many a lonely sufferer from anterior poliomyelitis may be happy to associate with fellow-sufferers who have faced and largely overcome the problems of this terrible scourge, and we appeal to members of the medical profession to bring our existence to the notice of any polios they may be treating. Briefly, our objects are:

1. To associate sufferers from infantile paralysis in fellowship for the encouragement and development of their interests and abilities.
2. To find means of training its members and, where necessary, of re-educating them, for occupations in which they can support themselves and make their contribution to the economic and social life of the community.

Jittery Legs and Burning Feet

SIR,—The condition described by Dr. C. A. Jackson under the heading "Jittery Legs and Happy Feet" (March 30, p. 505) appears to be identical with the "burning feet" syndrome already fully described by C. Gopalan (*Ind. med. Gaz.*, 1946, 81, 22). This author also refers to previous reports by Paraita and Stannus (the latter reference being *British Medical Journal*, 1944, 2, 140). It is not clear whether Stannus used the term "burning feet," but that term was certainly used by Ackroyd of South India in a private communication to the then hon. secretary of the Assam Branch of the B.M.A. in either 1943 or 1944.

The condition is found, chiefly, in S. India, under conditions rather similar to those encountered by Dr. Jackson—i.e., in people living on diets poor in riboflavin but containing par-boiled rice and, therefore, sufficient aneurin to prevent the development of beriberi. That the condition is not due to lack of riboflavin itself was shown by Gopalan by the fact that riboflavin was not curative. The syndrome, together with the associated ariboflavinosis, was cleared up by autolysed yeast, and the syndrome itself was found to be curable by pantothenic acid, which had no effect on the associated ariboflavinosis.

While stressing that credit should be given to Gopalan for his full description and careful assessment of the therapy of this condition, one must congratulate Dr. Jackson on his very careful observation of the cases he saw among his fellow P.O.W.s.—I am, etc.,

Hoogrijan, Assam

KEMPTON P. HARE,
Medical Officer, Tingri Medical Association.

Socialism and the Pay-bed

SIR,—The resolution of the association representative of medical officers employed whole-time by the Middlesex County Council (Dr. Davies's letter, June 1, p. 847) prompts me to rebut the view expressed that "the pay-bed system in hospitals should terminate altogether; patients should receive extra privacy, etc., solely on medical grounds." These people appear to have lost their sense of values. Have they lived in this community without the infinite disparity of individuality and quality making any impact on their consciousness, or are they incapable of appreciating the vast diversity in different individuals as regards intellectual endowments? Has a man whose whole life represents strenuous effort at perfection in the art of living, using this term in its highest sense, and who has acquired a fine level of intellectuality and sensibility, to be thrown, when sickness occurs, without any attempt at selection or segregation, into a mixed company, necessarily containing, among others, the scourgings of the community, such as have led self-indulgent, rude, vulgar, and perhaps even criminal lives, whose background is utterly foreign, antipathetic, and incompatible? Has it occurred to the signatories of this resolution that their proposal would add severe mental suffering to already existing physical sickness and would impede recovery, and that this mental suffering would be most acute amongst the highest types, those to whom the community, if it only knew it, owes most and in whom, as progenitors, the hopes of future generations lie? Many of these would rightly and understandably refuse general hospitalization.

This kind of irresponsible thoughtlessness is unworthy of our learned profession. It panders to the Socialist desire for a levelling out, which resolves itself so often into a levelling down. Numerous similar acts of folly, aimed undoubtedly at wealth as such, forget or ignore the fact that there is a real aristocracy of natural intellectual endowment, character, rectitude, social desirability, and service (not the class usually referred to as aristocrats, who may or may not be desirable eugenic types). That these superiors may be found at many financial levels in the community goes without saying, but they are ruthlessly dragged down and obliterated in the vortex of Socialist revenge.

The stamping out of desirables goes on apace, and it cannot too often be emphasized that once lost these cannot be replaced. It is this dysgenic effect of Socialism which is its principal menace and condemnation. Socialism, so called, is in fact anti-social in many of its aspects. It takes no account of genes, and will eventually and inevitably drag down the quality of the whole nation. Medical men, trained as they are in biology and in a position to understand genetics, should see the implications of this and many like moves. Good hygiene and prolonged

education will not replace desirable genes, which, once lost, are gone for ever. On our profession largely rests the responsibility of holding a correct balance between Nature and nurture and of instructing the community in biological affairs. They should show independence of thought and refuse the kind of subservience of which this document is suspect.—I am, etc.,

Grasmere.

JAS. B. MACALPINE.

In the Words of Eliza Doolittle

SIR,—Dr. A. S. Barr's letter (June 8, p. 891) calls for some comment. On what grounds did he put his totally hypothetical question to his "local Spens Committee"? There were never any grounds for believing that the official committee would suggest a maximum of £1,500 per year for a practice as large as Dr. Barr's must be. Naturally enough the members of his committee replied with the words indicated; there are hundreds of other underpaid occupations which they would have found equally unattractive. It would have been more interesting to have been told their replies to the original question as to what remuneration they would have expected for the work indicated and to have compared these with the amounts proposed in the official Spens report.

There is one other interesting aspect of Dr. Barr's letter. He is obviously trying to attract sympathy for the "poor overworked doctor." It is possible that Dr. Barr did have to work as hard as he indicates during the war, when medical manpower was stretched to the limit. It is more than probable that his remuneration was considerably in excess of £1,500 a year and that he was looking after far more patients than any man can or should care for under the rather easier circumstances now existing. Perhaps he will now take unto himself an assistant, or, better still, will give a share in his overworked practice, free of premium, to some young man who has spent five or six years in the Forces, and will be only too happy to ensure that Dr. Barr can have most evenings, his half-day, and most Sundays free from the ties that he deprecates. Incidentally, what would happen if Dr. Barr refused to sign certificates during his meal hours?—I am, etc.,

Margate

M. CURWEN.

GENERAL MEDICAL COUNCIL

ELECTION OF DIRECT REPRESENTATIVES

The result of the voting in the recent elections of five direct representatives for England, one for Scotland, and one for Ireland, was as follows:

IN ENGLAND		
Harry Guy Dain, M.D., F.R.C.S.	..	12,208
Sir Ernest Kaye Le Fleming, M.D., B.Chir.	..	11,477
Noel Everard Waterfield, M.B., F.R.C.S.	..	10,081
John Wardle Bone, M.B., B.Sc.(P.H.)	..	9,822
Edward Andrew Gregg, L.R.C.P.&S.I.	..	9,776
Leslie William Hefferman, M.D., F.R.C.S.	..	4,556
James Edgar Outhwaite, M.B.	..	4,459
William Walters Sargent, M.B., M.R.C.P.	..	4,103
William Fraser, M.B.	..	3,738
William Macleod, M.B.	..	3,412
Albert James Clarke, M.B., M.R.C.S.	..	3,378
Gordon Reginald Ward, M.R.C.S.	..	3,202
Louis Francis Beccle, M.B., M.R.C.S.	..	2,950
IN SCOTLAND		
Robert William Craig, O.B.E., M.D.	..	2,490
James Burnet, M.D., F.R.C.P.	..	1,107
IN IRELAND		
Frank Kane, M.D., D.P.H.	..	1,334
Alfred Charles Seymour, M.B.	..	535

The following medical practitioners have accordingly been elected members of the General Council of Medical Education and Registration of the United Kingdom for a period of five years from June 30, 1946:

Dr. H. Guy Dain, Sir Kaye Le Fleming, Dr. N. E. Waterfield, Dr. J. W. Bone, and Dr. E. A. Gregg, representing the registered medical practitioners resident in England.

Dr. R. W. Craig, representing the registered medical practitioners resident in Scotland.

Dr. Frank Kane, representing the registered medical practitioners resident in Ireland.

Obituary

A. G. NICHOLLS, D.Sc., F.R.S.C. (C.P.C.)

We much regret to announce the death of Dr. A. G. Nicholls, who retired on grounds of health from the post of Editor of the *Canadian Medical Association Journal* in 1942, his friendship was valued by many colleagues in the country and he upheld the tradition of cordial good will between the B.M.A. and the Medical Association.

Albert George Nicholls was born in 1876 at St. John's, New Brunswick, and went to Canada as a boy, growing up at the Montreal High School with the Davidson gold medal and the Lansdowne silver medal. He entered McGill University after obtaining his B.A. with a gold medal in classics began his studies in the medical faculty, where he graduated in 1894 with the final prize, and received the D.Sc. degree on his return to postgraduate study in Germany and Austria. He was a member of the teaching staff at McGill for seventeen years and became professor of pathology at Dalhousie University and provincial pathologist for Nova Scotia. During the war, 1914-18 he was D.A.D.M.S. to a Military Division at Halifax with the rank of major, and returned to Montreal in 1921. He became widely known as an accomplished writer on medical subjects, and was co-author with the late Prof. J. G. Adams of *The Principles of Pathology*. A man of wide interests and culture, Dr. Nicholls wrote some fifty monographs and other medical and historical publications, and succeeded the veteran Dr. A. D. Blackader as Editor of the *C.M.A.J.* in 1929. In the words of an editorial tribute in our contemporary: "No teacher was too great for him in the editing of material, and if at times he seemed to be over-scrupulous he usually had something to show for it. He himself was possessed of an unusually lucid and easy style which had been acquired over many years of writing but was partly also a reflection of his clear and orderly mind. To this he added a temperament which was never ruffled and a dignified tenacity of purpose. His pleasant, easy manner was greatly missed when he retired from his editorial work, to which he was so attached and which he did so well." To this we would like to add a line of gratitude and appreciation on behalf of British visitors to Canada, who enjoyed the hospitality of Dr. and Mrs. Nicholls and owe them thanks for many acts of kindness.

JAMES TAYLOR, C.B.E., M.D., F.R.C.P.

Dr. James Taylor, who died in London on June 6 aged 87, had long outlived his fellow-members of the famous group of neurologists who worked at the National Hospital, Queen's Square, during the close of the nineteenth century, which included John Hughlings Jackson, William Gowers, David Ferrier, and Victor Horsley. He was joint editor with Sir William Gowers of the *Manual of Diseases of the Nervous System*, which went into a third edition in 1899, and published *Paralysis and other Diseases of the Nervous System in Childhood and Early Life* in 1905. He edited the *Neurological Fragments* of Hughlings Jackson, with a biographical memoir, in 1925, and was responsible for the two volumes of Jackson's *Selected Writings* six years later.

Born on March 17, 1859, at Forbes, Moray-shire, son of Peter Taylor, he was educated at Forbes Academy and the University of Edinburgh, where he graduated M.A. with honours in natural science in 1883, M.B. in 1886, and M.D. in 1890. After working in Edinburgh as resident physician at the Royal Hospital for Sick Children and the Royal Infirmary he visited neurological and eye clinics in Germany and then became house-physician, and afterwards pathologist, at the National Hospital for Nervous Diseases, in Queen's Square, London; later he was elected to the honorary staff there, and to the Moorfields Eye Hospital as physician; also to the Queen's Hospital for Children in Bethnal Green. He became a Fellow of the Royal College of Physicians of London in 1897. He had been medical referee to the Pensions Commutation Board and a member of the consultant staff of the Convalescent Home for Officers at Osborne; he was also for a long time honorary physician to the Royal Scottish Corporation, and chief physician to the Guardian Assurance Company, and deputy medical referee to the Treasury. He was created C.B.E. in 1920.

At the Royal College of Physicians James Taylor had been a member of the Council for three years and examiner in 1920-4. His long service on the staff at Moorfields and the appreciation of his ophthalmic colleagues were marked by his election as president not only of the Neurological but also of the Ophthalmological Section of the Royal Society of Medicine, and for a time he acted as secretary of the Ophthalmological Society of the United Kingdom; he had also been president of the Harveian Society of London. He joined the B.M.A. in 1894 and in the following year was secretary of the Section of Psychology at the Annual Meeting in London; in 1913 he held office as president of the Section of Neurology and Psychological Medicine at the Brighton Meeting. His last published writing was a note on herpes zoster and chicken-pox which appeared on Sept. 22, 1945 in these columns; it was a postscript to earlier contributions of his on that subject in 1920.

Dr. GORDON HOLMES, F.R.S., writes:

The death of Dr. James Taylor has removed another from the survivors of a generation that inaugurated a new era in medicine and particularly in neurology. For several years he was closely associated with Hughlings Jackson and Gowers in both their private lives and their hospital practices, and after their retirement he carried on the tradition of careful clinical investigation and scientific analysis of symptoms that distinguished their work in the wards of the National Hospital. He collaborated with Gowers in the revision of the first volume of his *Selected Writings*, and by republishing many of Jackson's more important papers in *Neurological Fragments* and *The Writings of Hughlings Jackson* brought to more general notice the work of one who has had an exceptionally influential role in the development of modern neurology.

Taylor was on the whole reserved, but those privileged to enjoy his friendship found in it warmth, sincerity, and unassuming sympathy and readiness to help and advise. Outstanding features of his character were tolerance and practical common sense. That the latter distinguished his professional work was shown by the frequency with which he was consulted by fellow practitioners in search of advice in their own illnesses and those of their relatives.

A. F. VOELCKER, M.D., F.R.C.P.

Dr. Arthur Francis Voelcker, consulting physician to the Middlesex Hospital and to the Hospital for Sick Children, Great Ormond Street, died at his home in Cornwall on June 9, aged 84.

He was born at Cirencester in 1861, the fourth son of Prof. Augustus Voelcker, F.R.S., the agricultural chemist. Educated at University College School and Hospital he qualified in 1884, took the M.B. and B.S. (Lond.) degrees with honours in 1886, and proceeded M.D. two years later, after postgraduate study in Berlin, Vienna, and Paris. He was for twenty years a member of the visiting staff of the Hospital for Sick Children, and after his retirement from active work at the Middlesex he was elected consulting physician to that hospital and emeritus lecturer on medicine in the medical school; he was also for a long time honorary physician to St. Luke's Hospital when it was in Old Street, and consulting physician to St. Columba's Hospital, St. Saviour's Hospital, the Surgical Aid Society, the London City Mission, and other charities. During the 1914-18 war he held a commission as major, R.A.M.C.(T.). He had been elected a Fellow of the Royal College of Physicians in 1897 and served on its Council in 1918-20.

Voelcker examined in medicine for the University of Aberdeen, the University of Birmingham, the English Conjoint Board, and the Society of Apothecaries; he had been president of the Section of Medicine of the Royal Society of Medicine, and honorary librarian, and in 1918 president of the Medical Society of London. He joined the B.M.A. in 1886 and held office as vice-president of the Section of Diseases of Children at the Brighton Meeting in 1913. He published a number of articles, mainly on paediatrics, in this and other journals, and contributed to the *Encyclopaedia Medica*, to Garrod and Batten's *Diseases of Children*, and to the *Index of Treatment*. After retirement from active medical work he went to live at Marhamchurch, near Bude in North Cornwall, where he enjoyed fishing, shooting, and gardening, and the company of old friends. While an undergraduate he had distinguished

himself in athletics as a member of the L.A.C., and twice in his middle years of life the London medical students elected him president of the United Hospitals Athletic Club.

H. G. EARLE, LL.D., M.B.

Dr. Herbert Gastineau Earle, who became director of the Henry Lester Institute of Medical Research and Preventive Medicine, Shanghai, in 1928, died suddenly on June 5 at sea after a short illness.

He was born at Acton, Middlesex, on Aug. 10, 1882, and from the City of London School entered Downing College, Cambridge, in 1901 with a foundation scholarship, and gained first-class honours in the Natural Sciences Tripos of 1903. After clinical study at the Westminster Hospital he took the M.A. and M.B. degrees at Cambridge in 1913, by which time he had been for some years demonstrator of physiology at the Middlesex Hospital Medical School and joint lecturer on biology. In 1915 Earle was appointed professor of physiology in the University of Hong Kong and was for some years Dean of the Faculty of Medicine; the University conferred on him the honorary degree of LL.D. when he resigned his chair in 1927 to become director of the Henry Lester Institute at Shanghai. He published a number of papers in this and other journals on the physiology and pathology of the pancreas and on basal metabolism, and took a keen interest in the assessment of physical fitness and physiological anthropometry. His observations on the basal metabolism of Chinese students were presented to the XIIth International Congress of Physiology, held at Stockholm in 1926.

Earle joined the B.M.A. in 1914 and was president of the Hong Kong and China Branch in 1919; he had also been chairman of the Research Council of the Chinese Medical Association for eight years and served on a number of other scientific councils and committees. He acted as delegate from China at the Congress of British Universities on three occasions—Oxford 1921, Cambridge 1926, and Edinburgh 1931.

Dr. JAMES L. MAXWELL, C.B.E., writes:

The death of Dr. H. G. Earle is a serious loss to scientific research in medicine in China. Some 18 years ago, when Earle already occupied an outstanding position as professor of physiology in the University of Hong Kong, he received a very pressing invitation to accept the appointment as director of the Henry Lester Institute of Medical Research in Shanghai. The institute was then in the process of development, and it was essential for its success that a director be chosen who was outstanding in his profession, a good organizer, and one who could hold the confidence alike of his British and Chinese staff. The choice fell unanimously on Earle, and his appointment proved a success in every way.

Dr. Earle suffered internment at the hands of the Japanese when Shanghai was seized, and the long confinement, under very adverse conditions, seriously undermined his health. Dr. Earle was regarded, alike for his personal and professional qualifications, with genuine affection by Chinese and foreign friends in Shanghai and throughout China, and was greatly esteemed for his outstanding Christian profession. His loss to the cause of scientific progress in medicine in China is a very serious one.

The death of Mrs. RENNIE MACINNES, M.B.Lond., means the loss of a friend to many, not only at home but in Palestine, where as wife of a former Anglican Bishop in Jerusalem she was for many years a prominent figure, noted for her practical interest in religious and social activities. Janet MacInnes spent her early married life in Cairo, where her husband was then a missionary. Before the end of the first world war she moved to Jerusalem and assisted Bishop MacInnes in the work of the Syria and Palestine Relief Fund. In addition to this work for the victims of war and famine, she engaged for many years in practical efforts for the amelioration of conditions for women and girls, assisting the Government welfare worker in combating the many social evils which were found in Palestine. In this her medical knowledge (she had qualified in 1899) proved an asset. In the early days of the Palestine mandate she helped to create a voluntary society of women of different races and creeds, which opened a rescue home and inaugurated other social services, later to be taken over by the Government. Mrs. MacInnes was an attractive speaker and much in demand as a chairman. After the Bishop's death in 1931 she became secretary of the Palestine Mission of the Church Missionary Society. People of all kinds turned to her in perplexity and gained benefit. In spite of multifarious activities she seemed to have a reserve of strength which made her serene and unhurried.

Dr. WILLIAM ROBERT JAMES GARSON, who died recently at the age of 87, was for many years one of the best-known practitioners in Wirral and had been a member of the B.M.A. since 1881. When he retired from the post of medical officer to the Wirral Joint Hospital Board tributes to his long and valuable service were paid and he was appointed honorary consultant. He studied medicine at the University of Edinburgh, graduating M.B., C.M. in 1880, and some of his undergraduate years at Edinburgh were spent while Lord Lister was there. He knew intimately and hero-worshipped Henry Drummond, who stayed with him for fishing holidays in the Orkneys when he was a boy, and he later met Drummond when he used to lecture to the students in Edinburgh and Glasgow. After recovering from typhus in an epidemic in Newcastle-upon-Tyne, where he worked in "The Dispensary," and at the Ear and Throat Hospital Dr. Garson settled in practice at Bebington, Cheshire, retiring in 1943 after 60 years in practice. He was medical officer to the Wirral Fever Hospital from the time when it began work. He leaves four sons and one daughter. Two sons are medical men—Mr. Philip Garson, F.R.C.S.Ed., of Liverpool, and Dr. H. L. Garson, who is a general practitioner at Bromborough and was a brigadier in the recent war. His daughter married the late Dr. H. B. Weir, the London pathologist who used to assist Sir Bernard Spilsbury.

Medical Notes in Parliament

HEALTH SERVICE BILL

Before the Standing Committee adjourned on June 6 four further clauses of the Health Service Bill were examined. Mr. PIRATIN, on Clause 22, moved that arrangements under the Clause should include the provision of day and residential nursery accommodation. Mr. SOMERVILLE HASTINGS supported the amendment. Mr. BEVAN said he intended, when asking local authorities to plan their schemes, to make provision for day nurseries, but it was not practicable to do this everywhere. The demand for these nurseries varied enormously, and in some the overhead charges were very heavy for looking after a small number of infants. The amendment was defeated by 32 to 1.

In the same Clause Capt. BAIRD moved to add that it should be the duty of every local health authority to arrange for the dental care of persons who had reached compulsory school age but had not attained the age of 18. Mr. BEVAN replied that this matter was already sufficiently covered. What was really limiting was the number of dental surgeons. It was no good providing under the Bill for more dental care when this would be limited by the number of dentists. The amendment was withdrawn.

Mr. BEVAN accepted an amendment allowing a local authority to make contributions to a voluntary association which cared for children under 4 years of age but did not concern itself with expectant mothers. Answering a question by Mr. Reid about the charges which, under subsection 2 of the Clause, local authorities could recover, Mr. BEVAN said the scale of such charges would be known and had to be approved by the Minister before it became the scale on which the local authorities could recover. The services could not be provided without the means of the people concerned being considered. There would have to be a means test. The Clause as amended was added to the Bill.

On Clause 23 Cmdr. GALBRAITH remarked that subsection 3 appeared to give power to local authorities to lay down the qualifications of medical practitioners. Mr. BEVAN replied that was not for the local authorities to decide. A definition of what was a specialist, or a person with special qualifications, would be decided before long on the advice of the profession. The Clause was ordered to stand part of the Bill.

Mr. MESSER, on Clause 24, said the National Association for the Prevention of Tuberculosis was concerned about what would happen to specially trained visitors under the Bill. Mr. BEVAN said it was proposed that the Regional Boards should employ the health visitors of the local authorities, and a link would thus be established between them. The Clause was ordered to stand part of the Bill.

"DISTRICT" NURSING

On Clause 25, which deals with home nursing, Mr. REID moved an amendment in order to raise the question whether the local health authority should set up its own organization of nurses employed by it, and also whether this type of nursing should be limited to nurses who had received a special course of training. He said home nursing differed in many ways from nursing in a hospital. He hoped Mr. Bevan would do nothing

to supersede the good organization which at present employed these nurses all over the country. Mr. BEVAN said it was in the interest of that excellent organization that the words of the Clause should be unaltered. They left the local authority free to employ a suitable voluntary organization or to employ nurses itself. Local authorities, in the plans submitted, would have to satisfy the Minister that they were making considerable use of the voluntary organizations available.

Mr. Reid withdrew his amendment and Clause 25 was added to the Bill.

The Committee adjourned till June 18.

The General Medical Council

On June 7, during the debate on the motion for the Whitsuntide adjournment, Dr. MORGAN intervened to draw attention to the judicial tribunal which governed the conduct of the medical profession. He said this body could make its own crimes and misdemeanours but could inflict only one sentence. That tribunal was the General Medical Council.

Mr. Keeling and Mr. Callaghan protested at Dr. Morgan interposing this subject.

Continuing, Dr. Morgan said the G.M.C. was an undemocratic body with only seven elected members out of 42. The procedure was unlike that of any other tribunal in this country. The G.M.C. made its own procedure. It decided what was evidence; it could decide to discard evidence or to insist on cross-examination on evidence which the tribunal had not heard orally. Members who heard the original complaint and decided that there should be a trial also sat in judgment on the accused. He was allowed to be represented by counsel. The G.M.C. had a legal assessor. That assessor had the right to cross-examine the accused person while, so far as was known, counsel for the accused person had no right to cross-examine other witnesses. This degraded form of topsy-turvy justice had existed for 100 years without a change. The G.M.C. was a prejudiced partisan body. Dr. Morgan said he had counsel's opinion showing that evidence given before the tribunal need not be sworn. It might be written and not declared in open court. There need not be cross-examination. Every possible obstacle to an accused's being able to state his case was put in front of him. Dr. Morgan then alluded to the recent case of Dr. Hennessy. He said he did not ask for legislation, but for an inquiry by a Royal Commission, a Select Committee, or other means. He asked that the procedure of the G.M.C. should be changed and reformed, but that this should not be done in private within the profession. Doctors had had 100 years to reform the G.M.C. and had not done so. Gentlemen who had the highest degrees in medicine and whose personal character was, as a rule, unassailable would perpetrate injustices of the most despicable kind against their colleagues even when the evidence could not be used to condemn the worst criminal. The legal assessor, when summing up for the council, did not advise in public but *in camera*. The legal assessor cross-examined the respondent but not the complainant. The respondent had no right of appeal to the High Court. The case could be reopened only by the G.M.C. The only sentence it could impose was one of erasure. It could indulge in the mental torture of postponed sentence for a year or for six months. The anaesthetist of Sir Herbert Barker was struck off the roll, but the G.M.C. did not say anything to specialists who attended a demonstration by Sir Herbert Barker in one of the teaching schools. Dr. Hennessy had to fight alone because, when erased, he lost his membership of the Medical Defence Union. Dr. Morgan challenged the Labour Government not to allow the medical profession to hold its own investigations.

Mr. KEY said Mr. Herbert Morrison had asked him to reply. It had, Mr. Key remarked, been definitely accepted that some reform of the Medical Acts was necessary and the Goodenough Interdepartmental Committee had made certain recommendations on the point. The G.M.C. itself had been considering the question for some 18 months, and was going forward with certain proposals. The Government intended, if time could be secured in the coming session, to put forward its own proposals, and that a medical Bill should be introduced.

The DEPUTY SPEAKER said Mr. Key was not entitled in the debate to deal with legislation.

Mr. Key said the Government regarded an inquiry as inappropriate because it had already settled that the matter should be dealt with adequately and properly. The Government wished to study the information which had been provided and to consult with the profession and the people interested. The points which Dr. Morgan had raised would be borne in mind. It would be unfortunate if the impression got about that it was a general thing that members of the medical profession could be struck off the Register arbitrarily for some slight

offence. The G.M.C. could work only within the powers conferred on it by Parliament. In general the council discharged its disciplinary functions ably and carefully and with a sense of grave responsibility. That there was no appeal against its decisions was not the responsibility of the G.M.C. Criticism had been made of the constitution of the G.M.C.; on that he could say nothing regarding the proposals of the Government. Due consideration would be given before the proposals were put before Parliament.

E.M.S. Hospitals

Mr. KEY told Dr. Segal on June 6 that most E.M.S. beds had been beds reserved in the country's ordinary hospitals, supplemented by additional accommodation. As E.M.S. reservations diminished, the beds were normally left available for ordinary use. Reservations were 47,344 on Dec. 31 last and 35,000 at May 31. They would go on diminishing. The Ministry of Health would take every step to prevent premature closing of hospital beds. The difficulty was not so much availability of beds as of staff.

Mr. BEVAN told Dr. Segal on June 6 that the Leatherhead Emergency Hospital would be closed before the end of this year. The residual cases would be pensioners for whom the Ministry of Pensions would accept responsibility.

Emergency Hospitals in Scotland

Mr. McKINLAY on June 4 asked for a statement regarding the future of the emergency hospitals built during the war and administered by the Department of Health for Scotland. Mr. WESTWOOD answered that these hospitals, although intended originally for air-raid casualties, had treated large numbers of patients who were in the Services or auxiliary organizations or who became the responsibility of the Ministry of Pensions. The numbers of patients in these classes were falling, but were still substantial and must be regarded as a first commitment. Certain classes of civilian patients had already been admitted. He proposed to extend the arrangements for the admission of such patients in order that the hospitals and the special facilities they provided might serve the people of Scotland as a whole. The extent to which they could do so depended primarily on the numbers of medical, nursing, and other staff available. He hoped the existing staffs, including members of the Civil Nursing Reserve, would continue on the new basis. The new arrangements would take some time to bring into full effect, but before the National Health Service came into operation these hospitals should have found their proper place in the permanent hospital system of Scotland.

Specialists in the R.A.M.C.

Major LLOYD asked on June 4 whether Mr. Lawson knew that at Aug. 31 specialists of the R.A.M.C. would be 15 groups behind other medical officers and two groups behind other ranks in release. Mr. LAWSON replied that specialists were generally older than other medical officers on entry into the Army, and there was, therefore, a far larger proportion of specialists in the early age-and-service groups. This made it inevitable that their release programme should fall behind that for general duty medical officers. Specialists were being released as rapidly as the requirements of the Army allowed, and about 70% of those serving in June, 1945, had already been released. In the interests of serving soldiers he could not allow any serious deterioration in specialist services. To assist in meeting the Army's requirements specialists would in future be accepted on an eighteen-months engagement. He hoped that this would increase the intake from civil life.

Sir E. GRAHAM-LITTLE on June 6 asked whether Mr. Lawson was aware that there was a waste of specialist surgical experience in the R.A.M.C. An example furnished to him in the India Command was of a London graduate holding the qualifications M.S., F.R.C.S. assigned to duties within the capabilities of a G.D.O. Mr. LAWSON said every effort was being made in India and elsewhere to economize in specialist establishments wherever possible, but difficulties were presented by the fact that units were scattered over large distances and might require specialist assistance at short notice. He was inquiring into the specific case of alleged waste of specialist skill of which Sir Ernest had sent particulars.

Free Hearing Aid

In the House of Lords on June 5 Lord WALKDEN announced that a new hearing aid would be manufactured as a Government monopoly and distributed free to all who needed it through the National Health Service. The Medical Research Council had evolved a hearing aid which was believed to be an improvement on anything known before. Free issue was

expected to begin in 1948. Until then it would be provided at cost price, about £10, through the hospitals. Free maintenance, servicing, and new batteries would be available except in cases of damage through the patient's own carelessness. The Electrical Acoustics Committee had also recommended approved equipment for testing the degree of deafness. This would be supplied to clinics free of charge.

Vaccination and Inoculation.—Mr. LAWSON told Mr. Braddock on June 4 that Army instructions issued on Feb. 20 stated that inoculation and vaccination were voluntary. Mr. Lawson believed this was well known throughout the Army. These instructions referred to Service personnel and their families. The question of the inoculation and vaccination of families proceeding over-seas was under discussion. Difficulties arose because it was laid down by some foreign countries that vaccination and inoculation certificates must be produced as a condition of entry into the country concerned. Present instructions therefore stated that certain types of vaccination and inoculation must be carried out before passage could be allowed.

Extra Food Allowances.—Mr. STRACHEY stated on June 5 that a list of the conditions for which extra foods were allowed had been circulated to all registered medical practitioners. He added that it would not be in the general interest to publish this information. The medical advisers of the Ministry of Food were strongly against publication, but he would look into the matter again. Hunger, Mr. Strachey remarked, was not a disease.

Notes in Brief

Patients suffering from infectious diseases such as measles and scarlet fever, when isolated at home, are entitled to an extra soap ration if confined entirely to bed for a period longer than one month.

In Tanganyika 5,372 cases of sleeping sickness were reported during the years 1936 to 1945 inclusive, of which 2,527 were fatal. Of 86 cases reported up to the end of April this year, 16 were fatal.

At May 13, 31,612 vacancies were notified to the Ministry of Labour for all grades of nurses and midwives.

The committee considering the future of the x-ray industry includes Mr. Warburton, lately Director of Medical Supplies, Ministry of Supply (chairman), Brig. McGrigor, consultant radiologist to the War Office, and Dr. Russell Reynolds, radiologist.

The Services

Dr. William Evans has been appointed consulting cardiologist to the Royal Navy.

The following appointments and mention in dispatches have been announced in recognition of gallant and distinguished services while prisoners of war:

C.B.E. (Military Division).—Col. (Acting) J. Taylor, O.B.E., R.A.M.C.

O.B.E. (Military Division).—Col. C. O. Shackleton, late R.A.M.C.; Lieut.-Cols. D. C. Bowic and L. R. S. MacFarlane; Lieut.-Cols. (Temp.) J. C. Collins and C. W. Maisey, R.A.M.C.

M.B.E. (Military Division).—Majors G. F. Harrison, A. C. King, and R. Ramsay; Majors (Temp.) H. M. S. G. Beadnell, F. J. Murray, M. T. Read, M.C., and E. C. Vardy; Major (Acting) P. R. Graves; Capt. G. Blair, K. P. Brown, F. E. de W. Cayley, A. H. R. Coombes, R. L. Lancaster, J. Markowitz, K. C. Matheson, J. C. McNeilly, C. C. Petrovsky, T. S. Protheroe, A. Roy, P. G. Seed, H. E. De-Wardener, R. D. Taylor, and A. J. N. Warrack, R.A.M.C.

Mentioned in Dispatches.—Major (Temp.) J. D. Fraser, R.A.M.C. The following appointments and mentions have been announced in recognition of gallant and distinguished services in the field:

O.B.E. (Military Division).—Major F. P. H. E. Orban, R.A.M.C.

M.B.E. (Military Division).—Major (Temp.) S. N. Varian, R.A.M.C.

Mentioned in Dispatches.—Major (Temp.) D. D. A. Fraser and Capt. D. R. Macauley, R.A.M.C.

The following appointments, awards, and mention in dispatches have been announced in recognition of gallant and distinguished services in Burma:

C.B. (Military Division).—Major-Gen. (Acting) W. E. Tyndall, C.B.E., M.C., late R.A.M.C.

C.B.E. (Military Division).—Brigs. (Local) J. C. Hawksley, H. L. Marriott, and M. F. Nicholls; Brig. (Temp.) G. E. Macalevey, D.S.O., M.C.; Brig. (Acting) A. Swindale, O.B.E., T.D.; Col. (Temp.) J. J. O'Dwyer, R.A.M.C. Brig. (Local) M. K. Alfridi, O.B.E., I.M.S.

O.B.E. (Military Division).—Lieut.-Col. (Temp.) D. J. Lawless, W. C. Mitchell, C. E. Moorhead, H. G. Page, M.B.E., W. Serle, and W. G. Sutcliffe, R.A.M.C. Col. (Temp.) J. L. Mewton; Lieut.-Cols. (Temp.) S. M. Basu, A. S. Rao, F. W. Snedden, and B. P. Srivastava, I.M.S. Col. (Acting) A. L. Craddock, M.B.E., Army in Burma Reserve of Officers.

M.B.E. (Military Division).—Majors (Temp.) A. B. Cook, B. H. Ellis, N. S. Martin, W. Minns, J. McD. Simpson, W. T. Walker,

D. B. Watson, and J. D. Younghusband; Major (Acting) H. D. Thompson; Capt. H. Acton and M. F. Ronayne, R.A.M.C. Majors (Temp.) S. Prakash and S. D. Singh; Capt. Hafiz-ur-Rahman and S. B. H. Gardezi, I.M.S. Majors (Temp.) S. F. Thomas and C. J. Todd; Capt. B. Singh and B. M. R. Choudhury; Capt. (Acting) V. P. Batra; Subadar C. Mani, I.A.M.C.

M.C.—Major (Temp.) J. Jacobs; Capt. D. R. Evans and G. H. Pimblett, R.A.M.C. Capt. H. N. Roy and S. A. Wadud, I.M.S.

Mentioned in Dispatches.—Capt. B. Bernstein, R.C.A.M.C. The following appointments and mentions in dispatches have been announced for distinguished service during the war in the Far East:

M.B.E. (Military Division).—Temp. Surg. Lieuts. T. W. G. Kinnear, S.A.N.F.(V.) and I. F. K. Muir, R.N.V.R.

Mentioned in Dispatches.—Surg. Cmdr. D. F. Walsh and Surg. Lieut.-Cmdr. E. B. Bradbury, R.N., Acting Surg. Cmdr. R. D. Bradshaw, Surg. Lieut.-Cmdr. W. P. G. Dickson, Temp. Acting Surg. Lieut.-Cmdr. J. Watt, and Temp. Surg. Lieuts. R. D. Maclean, I. S. Bergius, R. R. H. Lovell, and B. J. Webb, R.N.V.R.

Medical News

The annual general meeting of the Paddington Medical Society will be held at St. Mary's Hospital, W., on Tuesday, June 25, at 8.45 p.m., when films on gas-air analgesia in midwifery and on the production and distribution of medical gases will be shown.

A meeting of the Medical Society of the L.C.C. will be held at County Hall, S.E., on Wednesday, June 26, at 4.30 p.m., when Mr. W. Ritchie Young will open a discussion on "Dental Disease in its Relation to Ill-health."

The annual general meeting of the British Empire Leprosy Relief Association will be held at the India Office, Whitehall, at 3 p.m., on Wednesday, June 26, when addresses will be given by Sir Bernard Bourdillon, chairman of the executive committee, and Dr. T. E. Davey, medical superintendent of the Uzuakoli Leper Settlement in S.E. Nigeria.

A meeting of the Medico-Legal Society will be held at 26, Portland Place, W., on Thursday, June 27, at 8.15 p.m., when a paper will be read by Mr. T. Paterson Owens on "Approved Schools and Remand Homes."

The annual meeting of the Royal Society of Medicine will be held on Tuesday, July 2, at 1.30 p.m., when diplomas of Honorary Fellowship will be presented to Group Capt. Antoni Fiumel, late D.G.M.S., Polish Forces, and Col. Carel Frederick Koch, late D.G.M.S., Netherlands Forces, and the officers and council of the society for 1946-7 will be elected.

A final programme has now been issued for the National Conference on Maternity and Child Welfare to be held at Friends House, Euston Road, N.W., on Thursday and Friday, June 27 and 28. There are three main subjects for discussion: (1) planning a home, making a home, running a home; (2) incidence of dental disease and the care of the teeth of expectant and nursing mothers and children under 5 years; (3) care and treatment of the handicapped child. There will also be a show of films dealing with the care of the teeth. Dr. Jane H. Turnbull, chairman of the National Association of Maternity and Child Welfare Centres and for the Prevention of Infant Mortality, will open the conference at 10.30 a.m. on June 27. Mr. Aneurin Bevan, Minister of Health, will give his presidential address on June 28 at 10.30 a.m. Tickets (10s. 6d. each for two days, 6s. each for one day, or one session) may be had from the secretary, Miss M. R. Lovelock, 117, Piccadilly, W.1.

A Swiss doctor is offering free board and lodging to an English male student for three months beginning July 1. The student should be studying medicine or natural science, 22 years of age or older. If possible he should be a research worker or studying for a higher degree. For full details apply to the Secretary, British Medical Students Association, B.M.A. House, Tavistock Square, London, W.C.1.

A new and revised list of the names and addresses of all members of the British Institute of Radiology is very shortly to be published. Members are asked to take immediate steps to let the Institute know their present permanent address should this differ from that published in the yearbook for the session 1943-4. They should write to 32, Welbeck Street, London, W.1.

A notice was published in the *London and Edinburgh Gazettes* dated June 14, 1946, of the Secretary of State's intention to make Rules amending the Poisons Rules, 1935, and an Order amending the Poisons List. Copies of the proposed amending Rules and Order may be obtained from H.M. Stationery Office or through any bookseller, price 2d. and 1d. respectively.

Dr. Cyril Burt, professor of psychology at University College, London, received a Knighthood in the Birthday Honours List.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

At a Congregation held on June 3 the following medical degrees were conferred:

MD—J. N. Mills (by incorporation), J. Metcalf, R. L. Lancaster, S. C. Trelove.

MChir—A. G. Leacock (by proxy).

MB, BChir—J. G. Bentside, F. J. Conway.

UNIVERSITY OF LONDON

Sir Edward Peacock will present the prizes at the London Hospital Medical College in the Library on Thursday, June 27, at 3 p.m.

The Senate has decided to confer the honorary degree of D.Sc. on Prof. E. D. Adrian, O.M., M.D., F.R.S., F.R.C.P., and Sir Henry Dale, O.M., G.B.E., M.D., F.R.S., F.R.C.P., at a ceremony in November next, in connexion with the celebration of Foundation Day.

UNIVERSITY OF SHEFFIELD

At a meeting of the University Council, held on June 14; M. F. A. Woodruff, M.D., M.S., was appointed full-time tutor in surgery. The Council received the resignation of Dr. C. E. Davies of the post of part-time assistant tutor in medicine, and thanked him for his services.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The President and members of the Council entertained to dinner at the College on June 11 various overseas delegates to the Imperial Press Conference.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In England and Wales there were 644 more cases of measles than in the preceding week. The only other changes were decreases in diphtheria 67, and dysentery 37.

The largest variations in the returns for whooping-cough were increases in Carmarthenshire 31 and Essex 25, and a decrease in Staffordshire 43. Only 304 cases of diphtheria were notified—the smallest ever recorded; the largest decreases were Yorkshire West Riding 22, Durham 18, and Lancashire 11. In contrast to the general trend of diphtheria an increase of 17 was recorded in London.

The rise in measles was mainly confined to the counties surrounding London, though the incidence in London decreased by 67. The largest increases were Middlesex 144, Lancashire 131, Essex 90, Kent 54, Surrey 52, and Hertfordshire 43. Anglesey had 66 more cases in an outbreak which began last week with 101 cases.

The only new outbreak of dysentery was in Kent (Malling R.D. 17 and Cranbrook R.D. 11). Other large returns were Lancashire 28, London 15, and Warwickshire 11.

In Scotland rises occurred in the notifications of scarlet fever 33, whooping-cough 23, and diphtheria 12. The increase in scarlet fever was mainly contributed by Glasgow, where the notifications rose from 47 to 68. The largest rises in diphtheria were Glasgow 7 and Edinburgh 6.

In Eire the only changes were increases in measles 54, and scarlet fever 13. The rise in scarlet fever was general, while the rise in measles was mainly due to an outbreak in Wicklow, Rathdrum R.D. 40.

Quarterly Returns for Scotland

During the March quarter the births were equivalent to a rate of 18.1 per 1,000, which was 0.5 above the average of the five preceding first quarters. Infant mortality was 69 per 1,000 registered live births and was 15 below the five-years average. The general death rate was 16.3 per 1,000, being 0.1 below the average for the five preceding March quarters. The death rate from all forms of tuberculosis was 82 per 100,000, and from respiratory tuberculosis 66; these rates were 8 and 3, respectively, below the five-years average. Deaths from epidemic diseases included diphtheria 40, cerebrospinal fever 32, whooping-cough 24, and measles 19.

Week Ending June 8

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 987, whooping-cough 1,749, diphtheria 304, measles 3,896, acute pneumonia 546, cerebrospinal fever 47, dysentery 149, poliomyelitis 9, paratyphoid 2, typhoid 4, smallpox 3.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 1.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Articology Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate Westcent, London*.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Sycosis Barbae

Q.—How does one prepare an autogenous vaccine for sycosis barbae? How long does this take and how much would it cost?

A.—The stages in the preparation of an autogenous vaccine are the making of a primary culture, thence of a pure culture if necessary, the suspension of the growth in 0.5% phenol saline and its sterilization by heat, a test for sterility, and dispensing in ampoules or bottles. The whole process need not occupy more than three or four days unless the organism is of exceptionally slow growth, and this would not be so in the present case, since sycosis barbae is due to one of the most freely growing of common bacteria—*Staphylococcus aureus*. The preparation of such vaccines is undertaken by all practising clinical pathologists and laboratories who engage in work for fees; charges vary widely, but a reasonable fee would be between two and a half and five guineas.

The treatment of sycosis barbae with an autogenous vaccine alone is not usually successful. Penicillin in the form of a cream or spray has given excellent results in some cases, although relapse may follow. A test of the sensitivity of the staphylococcus to penicillin is advisable before this treatment is begun.

Artificial Pneumoperitoneum

Q.—Please describe the technique, results, and dangers of artificial pneumoperitoneum.

A.—This question is difficult to answer briefly. Artificial pneumoperitoneum has been used in the treatment of certain cases of mainly unilateral pulmonary tuberculosis in which artificial pneumothorax is either impossible because of adhesions or regarded as dangerous because of the acuteness of the disease and the consequent liability to pleural effusion or empyema. It is customarily combined with temporary or permanent phrenic nerve interruption, and its effect is to reinforce the rise of the diaphragm produced by this procedure. The puncture is usually made through the anterior abdominal wall, a little below the costal margin and just lateral to the rectus abdominis muscle. After the pneumoperitoneum has become established, refills may be more conveniently given through one of the lowest intercostal spaces in the flank. At the induction, and sometimes at the refills, no reading of pressure is obtained before the air is introduced, and the finding of the space is therefore a matter of skill and experience. The quantities of air usually introduced are much higher than in artificial pneumothorax, and average about 800 to 1,000 ml. When the pneumoperitoneum is established this quantity may be required at intervals of a week to a fortnight. The dangers of the procedure include air embolism, which does not appear to be more frequent than with artificial pneumothorax, and peritoneal effusion and tuberculous peritonitis, which are very much less common than the corresponding affections of the pleura in artificial pneumothorax. In addition, less serious complications, such as discomfort and dyspepsia from abdominal distension, and the production of inguinal and other hernias which may contain air, have been recorded.

So far as the results are concerned, the procedure is a relatively recently introduced one about which no agreed opinion has been reached. Some authorities have gone so far as to

claim that the results obtained have been so favourable, and the complications so few, that they recommend pneumoperitoneum even in cases which are suitable for artificial pneumothorax. Others feel that the procedure has certain limited indications—for instance, for the treatment of cavitating lesions situated in the lower lobe, especially in its dorsal segment, or in the treatment of acute pneumonic tuberculosis. In these latter cases a combination of phrenic nerve interruption and artificial pneumoperitoneum may tide the patient over the acute stage of the disease and enable an artificial pneumothorax, which would be dangerous at the onset on account of the risk of pleural complications, to be induced safely later on. Others are more sceptical still and regard pneumoperitoneum merely as a means of reinforcing the effect of, and having the same rather limited indications as, phrenic nerve interruption.

Remissions in Peptic Ulcer

Q.—What is the explanation of remissions in peptic ulcer? Why are these remissions usually so regular in their periodicity in any one case?

A.—In the present state of knowledge it is not possible to express dogmatically the reasons for remissions in cases of peptic ulcer. It must always be remembered that peptic ulcer may be present without symptoms. A huge ulcer becomes symptomless after treatment for a few days and, similarly, many patients adopt treatment only when pain recurs. In many cases, if not in all, "remissions" are merely the result of treatment, which the patient half-consciously adopts when pain returns.

Brow Presentation

Q.—Is Caesarean section the best treatment for brow presentations?

A.—The treatment of brow presentation naturally varies with its cause and other circumstances of the case. Thus, if the cause is a pelvic deformity there is little question that Caesarean section is the best treatment. The same is usually true when the patient is a primigravida. Sometimes, however, in multiparous patients there is a place for other lines of treatment, such as internal version. It is impossible to lay down a general rule, but there is no doubt that there has been an increased use of Caesarean section in these cases during recent years. This is largely on account of the adoption of the lower-segment technique, which can be carried out with reasonable safety for the mother, even when labour has been prolonged, and which offers the best chance to the child.

Benzyl Benzoate in Pregnancy

Q.—Is there any evidence for the statement that benzyl benzoate causes abortion in scabetic expectant mothers?

A.—There is no evidence that benzyl benzoate treatment for scabies has any effect on expectant mothers. The correct treatment is to give one application, which is left for twenty-four hours and then washed off in a bath. If necessary, and only if necessary, a second application is made one week later. Some doctors, however, do not realize that one application, or at most two, is sufficient treatment, and they give several applications, which causes dermatitis. This is certainly bad for anyone, including expectant mothers. Otherwise there is no connexion whatever between the treatment and the uterus.

Disorders of Calcium and Phosphorus Metabolism

Q.—What are the modern views regarding the relationship of blood calcium levels, blood phosphorus levels, and the calcium-phosphorus ratio, to (a) the muscular twitchings of uraemia, (b) infantile spasmodophilia, (c) hypoparathyroidism, and (d) the clinical state of "alkalosis"?

A.—In uraemia the serum calcium falls to extremely low levels (5 mg. per 100 ml. and less), the phosphate at the same time rising greatly, and the increased muscular irritability may reasonably be attributed to this reduction in calcium. In alkalosis, on the other hand, whether due to hyperpnoea, vomiting, or overdosage with alkalis, the level of the serum calcium is normal; but it is believed that owing to the change in reaction towards increased alkalinity a reduction in ionized active calcium occurs. Tetany is seen especially in the hyperpnoeic type and is relatively rare in overdosage. In hypoparathyroidism

the serum calcium shows a gross reduction and there is a considerable rise in the serum phosphate, to a level of 6 or 7 mg. per 100 ml. (normal 3 to 4 mg.). The primary disturbance would seem to be a fall in the excretion of phosphate by the kidney. Tetany appears with the fall in calcium, and can be relieved by the administration of calcium orally or by the parenteral route, or by raising the serum calcium by injection of parathormone or by very large doses of vitamin D. In infantile spasmodophilia appearing in connexion with rickets the calcium is also reduced, owing to defective absorption. Though the primary blood change in human rickets is a fall in the phosphate, believed by some to be due to overaction by the parathyroids in an attempt to compensate for the reduction in absorbed calcium, later the serum calcium may also fall and spasmodophilic symptoms appear.

Mycosis Fungoides

Q.—An unmarried woman of 37 has been suffering for the last seven years from mycosis fungoides. Is any treatment likely to effect improvement at this stage?

A.—Mycosis fungoides, like the leukaemias and Hodgkin's disease, is one of the reticulo-endothelioses, and, though sometimes responsive to natural or artificial shock therapy, in the majority of cases it is controlled only by radiotherapy. Presuming that the blood picture and sternal puncture reveal no abnormality in white cells and that clinical and x-ray investigation show no infiltrations in lungs or viscera, x-ray therapy should be given in small dosage (150 r units, unfiltered, at about 90 kV) to the whole body, and should be repeated every three or four weeks until the condition is controlled, the treatment being resumed if there is a relapse. A watch must be kept for the possibility of damage to blood-forming organs. In most cases a point is ultimately reached where the condition becomes unresponsive, and then there is little more that can be done. Internal treatment and local applications are of no avail.

Dermatitis in Concrete Workers

Q.—Please discuss the cause, treatment, and prevention of dermatitis contracted in the concrete industry (wet and dry processes).

A.—Dermatitis in this industry may be caused (1) by contact with cement, sand, and lime, with or without friction, or (2) from oiling or cleaning moulds. Measures for prevention are in the lines generally advocated—viz., selection of workers and their protection at work; supervision and inspection to detect early cases of skin irritation and to ensure cleanliness. Amplification of the scope of these preventive measures is given in P. 330 issued by the Factory Department of the Ministry of Labour and National Service, obtainable from H.M. Stationery Office. Treatment of cases of dermatitis in the concrete industry differs in no way from that from other industrial causes.

Burckhardt (*Schweiz. med. Wschr.*, 1938, 68, 783, and *Arch. f. Derm. u. Syph.*, 1938, 178, 1); J. G. Downing (*Arch. Derm. Syph.*, Chicago, 1939, 39, 12); L. Schwartz and L. Tulipan (*Occupational Diseases of the Skin*, 1939, p. 128, Philadelphia).

Subacute Combined Degeneration

Q.—A man of 51 has had pernicious anaemia for fifteen years, and for three years has received doses of liver extract. The symptoms of subacute combined degeneration have improved under treatment. His blood count is now 5 millions and his colour index 1.16. Is it wise to continue with 4 ml. of liver extract weekly?

A.—There is a good case for continuing with big doses of liver extract. Spinal degeneration responds only to unusually large amounts. There is some clinical support for the employment of vitamin preparations at the same time, and especially injections of B₁₂. One would be wise in also prescribing by mouth whole liver, liver extract, and desiccated hog's stomach. Polycythaemia is the most usual complication of excessive liver usage, and can be detected by periodic red cell counts. Sensitivity to liver extract is not likely to develop later in the course of treatment.

After-effects of Undulant Fever

Q.—Is there any useful treatment for the lassitude, arthralgia, myalgia, and fibrositis which still persist four years after undulant fever? Is it permissible to take amphetamine?

A.—No particular line of treatment for the pains described can be recommended with confidence. It would be worth while to make a meticulous search for one of the commoner sources of chronic infection which might be associated with chronic fibrositic pain, to investigate the possibility of some nutritional defect, or of degeneration or infection of the central or peripheral nervous system, and to exclude any abnormal vascular condition. The routine and prolonged use of amphetamine is not recommended, because of its occasional side-effects, the possibility of developing addiction, and its failure to remove the fundamental cause of lassitude. Chronic lassitude is usually infective or psychological in origin, and treatment should be directed at the cause.

INCOME TAX

Medical Officer: Car Expenses

J. M. bought a car on April 3, 1946, while seeking an assistantship. Shortly afterwards he accepted an engagement as medical officer to an industrial concern. The firm would supply the use of a car if J. M. didn't possess one. Can he claim a deduction for the use of his car?

A.—The rule is a rigid one: to be allowable an expense must be incurred wholly, exclusively, and necessarily in the performance of the duties of the office. If the facts are that J. M. can at any time call for the use of one of the firm's cars but in fact uses his own, the element of necessity seems to be eliminated and the claim would fail. If, on the other hand, a firm's car is not available in present circumstances but one would be made available if J. M. did not have one, there are some grounds for the claim. But in that case one would expect the firm to recognize the existing saving in their own transport service by making J. M. an allowance for using his own car.

Expenses: Domestic Servant; Car Replacements

"Q. Q." asks: (a) Is a practitioner entitled to treat as an allowable expense part of the cost of keeping a domestic servant, the servant having to take telephone messages, etc.; and if no servant is available may payment be made to a wife and charged as an expense? (b) A car was bought in 1940 for £50 and sold in 1941 for £75. In January, 1946, another car was bought for £294. "Q. Q." intends to buy a new car yearly and will probably expend about £400 on a new car in January, 1947. Can he claim as deductions the differences between what he receives and what he pays on each transaction?

A.—(a) Yes; but the claim must be reasonable having regard to the proportion of time spent on dealing with professional calls, and the amounts claimed must have been actually paid for the service in question. (b) The cost of renewal of a car can be claimed as an expense, but in so far as the payments made relate to improvement rather than to mere replacement they represent capital outlay and are not allowable. In the long run "Q. Q." will probably gain by claiming the initial and depreciation allowances now authorized for 1946-7 and future years.

Sale of Car: "Balancing Charge"

D. O. bought a car in 1939 for £140; wear-and-tear allowances have reduced the written-down value to £25. What will be the position if he now sells the car for £600?

A.—(It is assumed that D. O. will continue to practise after the sale of the car.) As the sale will take place after April 5, 1945, D. O. will be liable to a "balancing charge," but the maximum amount will be £140 - £25 = £115—i.e., the aggregate of the wear-and-tear allowances given in respect of the car.

Employment in 1943-4: Expenses

B. worked as a locum tenent from February, 1943, to January, 1944, in sole charge for an absent owner, and was required to live in the house formerly occupied by the latter. B. started practice on his own account in 1944. Can he claim: (a) some cancellation of the 1943-4 tax under the "P.A.Y.E." regulations; (b) "salary of wife and maid as allowed to the owner"; and (c) cost of running and maintaining car over and above an inadequate allowance?

A.—(a) As B. apparently was not "employed" after April 5, 1944, he did not in fact come under the "P.A.Y.E." system of tax deduction. He is accordingly not entitled to any cancellation of the tax assessed for 1943-4. (b) and (c) These expenses can be claimed in so far as it was necessary to incur them to fulfil the

conditions of service—and only if the payments were in fact made. The production of satisfactory evidence in support of the claim may, however, be a matter of some difficulty.

Non-resident Appointment: Travelling Expenses

"FUMUS" holds a full-time non-resident hospital appointment. He has to attend emergency cases at night and consequently some form of transport is necessary. Can he claim in respect of the cost of keeping a bicycle or car?

* We fear that the special circumstances would not be regarded as taking the case out of the general rule, which is that the expense of travelling between the residence and the place where the duties of an office are performed are not incurred in carrying out the duties and are therefore inadmissible.

Cash Basis or Earnings Basis

"DEMOBBED" restarted practice at May, 1945. Can he make his return for 1945-6 on the cash receipt basis?

* No; cash receipts during the early years of restarting a practice will not fully reflect the gross earnings or, consequently, the true profit earned. (It is assumed that tax was not paid by our correspondent on cash coming to hand from his former civil practice after he had ceased civilian work.)

Uniform Allowance: Territorial Army

E. W. was demobilized in 1945 but is on the active list as a major in the R.A.M.C. Territorial Army. Can he claim an allowance for upkeep of uniform, etc.?

* We understand that in such circumstances an allowance of £7 10s. is made from the pay issued in the course of each financial year.

LETTERS, NOTES, ETC.

Teaching of Surgery in Scotland

Dr. ARTHUR TURNBULL writes from Glasgow: Mr. Aneurin Bevan now states that the national health administration wants "the power to create new teaching hospitals." Does this mean the Ministry seeks a special brand of medical students to carry out the provisions of the Act? If the Minister has not enough doctors to run his show are the conditions of service such as to attract the best men? Army doctors are emigrating to the Colonies in batches. What is the trouble: poor pay or deprivation of freedom? Mr. Lloyd George set up treatment to the patient through the Government, the approved societies, and the doctors, and left the medical colleges to paddle their own canoes. He failed to correlate the training of the surgeon with the application of surgical technique to any one patient. He also failed to provide prompt benefits to the patient, and entirely failed to keep the Act up to date. The Ministry, simply moulder on, and the medical schools were left to provide curricula as best they might. To-day this process is to continue. What is the point in the process—a professor invited to describe surgical methods and technique to a student who is in effect debarred from carrying out an operation on his own patient after graduation?

Unless the Scottish universities move at once and provide a Scottish surgical service, the London Ministry will simply take over the training and so imperil and undermine the quality and status from the Scottish colleges. Replaced by drilled yes-men and routine quacks the Scottish degree will lose its value. Health will be commercialized, and many invaluable lives lost in practice. Therefore the principals of the four Scottish universities should draw up a scheme

Additional Qualifications of Dentists

In his address from the chair at the opening of the 49th session of the Dental Board Dr. E. W. Fish brought forward a minor problem, that of additional qualifications in the *Dentists Register*. Under the Dentists Act, 1878, it is laid down that medical qualifications granted in the United Kingdom or Ireland which are registrable in the *Medical Register* as primary or additional qualifications in medicine, surgery, or midwifery may be also placed in the *Dentists Register* as additional qualifications, and practitioners who are doubly qualified have been able for more than sixty years to register their medical qualifications as dental qualifications. But with the prospective amendment of the Dentists Acts on other grounds Dr. Fish suggested that some questions might arise as to the extension of additional qualifications which are registrable. At present the General Medical Council must be satisfied that (1) the additional qualification was granted after examination, (2) that the examination was held by one of the universities and corporations which choose members of the G.M.C., and (3) that the qualification was granted in respect of a higher degree of knowledge than is required to obtain a licence in dental surgery or dentistry. To take any of these requirements, would it be desirable in any amendment of the Acts to perpetuate the present exclusion of honorary

degrees from the *Register*? Further, should the "examination" requirement be waived, ought honorary degrees in subjects other than dentistry to be included? As to the second requirement, that the examination must have been held by one of the medical authorities in this kingdom, might not the right now be extended, so far as concerns additional qualifications, to diplomates of bodies of equivalent standing in imperial or even in foreign territories? Then there is the perplexing requirement that the qualification must have been granted in respect of "a higher degree of knowledge." What is a higher degree of knowledge? Is it sufficient to include general medicine and surgery, as has been done since the early 'eighties; or may the knowledge of which it is necessary to take account include the biological and physical sciences or, indeed, any other branch of learning? These seem to be minor matters, but they may have on occasion much importance. At present the whole question of the registration of additional qualifications is the business of the General Medical Council, which is bound by the conditions imposed on it by the Dentists Act of 1878, but it will become the business of the Dental Board or its successor if the unanimous recommendation of both bodies to the Interdepartmental Committee is translated into law, and in that event some re-interpretation of these old rules more in conformity with modern conditions may be expected.

Prevention of Baldness

Dr. E. GALLOP (London, S.W.1) writes: The aetiology of the rarer forms of baldness is not clear, but I do not think this applies wholly to the common form that embraces the great majority of cases—the bald vertex of the adult male. It is too familiar to need description. Yet there are certain points about it, obvious as they are, that deserve notice. It is confined to the crown of the head of the adult man. It does not occur in women or children. The body hair remains unaffected. In what way does the hair of the man's scalp receive treatment different from the rest of his body and from that of his sisters? The answer is so obvious that it attracts no attention. For countless years he has applied various substances to it. Our contemporary young man favours mucilage. His father preferred a scented grease, a brilliantine it was called; his great-grandfather a more frank oil, as his granny's antimacassars, protecting the furniture, indicated. The effect of these and others was the same. They smarmed down the hair, kept it in regulation order, but did not allow the individual hairs to breathe, and in due course they gave up the unequal struggle and fell out. Efforts were sometimes made to restore them. So-called stimulating hair lotions were employed. As well whip a dying horse. An irreversible change was in progress. It is all very curious. There is no intrinsic attractiveness in the well-pomaded head. Rather the reverse, in fact. The explanation, I think, lies far back—very far back, and is connected with the imperfectly understood objects and provenance of the custom of anointing the head for religious purposes. We are dealing, I believe, with a survival of a custom which has lost its functional meaning, but because of a deep innate conservatism, which makes us cling to the maintenance of old forms, remains now only for decorative purposes. One could give other examples of the same thing happening. But baldness is much to pay for the *status quo*, and occasionally unruly hair is better than none at all. To preserve it, perhaps all that is necessary is to refuse to be overrun by the minor tyrannies of fashion and to put *nothing* on it. This includes leaving the hair wet with water to keep it smoothly in place and, of course, it must be before the falling-out process has gone too far. Other factors are probably involved, but I believe that much the most important has been considered.

Treatment at Spas

Dr. G. D. KERSLEY (Bath) writes: Since publication of my letter (June 1, p. 848) it has been pointed out to me that, in addition to the three larger spa hospitals I mentioned in my original letter, there is a 30-bedded hospital for similar treatment at Woodhall Spa. I should like to apologize for this omission.

Varicella Herpetiformis

Dr. H. ANGELL LANE (Abbots Langley) writes: In the very interesting article by Drs. P. H. Peterson and S. A. B. Black (May 18, p. 762) it might be useful—as a prophylactic measure—to examine the blood for the presence of Türk cells. These are found (3 to 9%) in a great majority of cases of chicken-pox from the second until the sixth or eighth day of the rash. I have not found them in any of the cases of herpes that had no relation to chicken-pox.

Corrigendum

Mr. STANLEY WAY (Newcastle-upon-Tyne) writes: In a report of a paper on the lower-segment Caesarean section read by me to the North of England Obstetrical and Gynaecological Society (June 15, p. 926) the gross mortality for 500 cases is stated to be 3.4%. This figure is incorrect. There were seven deaths in the series and the gross mortality rate should therefore be 1.4%.

LONDON SATURDAY JUNE 29 1946

TYPHUS: EXPERIENCES IN THE CENTRAL MEDITERRANEAN FORCE

BY

HERBERT D. CHALKE, O.B.E., M.A., M.R.C.S., L.R.C.P., D.P.H.

Colonel, Late R.A.M.C.; Late Senior Hygiene Officer, Allied Armies in Italy

PART I

It is well known that the presence of communicable diseases among the civilian population of an occupied country may seriously affect the health of an army in the field. This is particularly true in modern warfare, in which large-scale destruction of towns takes place, with disruption of water, lighting, and sewage systems, and general disorganization of the municipal services. There is considerable movement of refugee civilians from place to place. Shortages of food, fuel, and soap affecting large bodies of people, under no sanitary supervision, still further increase the risks of outbreaks of disease. The breakdown of civilian medical arrangements—general medical practice, public health services, and hospitals—is another factor of much importance. One of the first results of this is the cessation of notification of cases of infectious disease; small foci of infection are thus undetected and unchecked until they have swollen into epidemic form. The Army hygienists, in particular those whose sphere of control is in the forward areas, have considerable responsibilities with regard to civilian preventive medicine. How important these are, and how vital it is to realize their importance quickly, was well demonstrated during the campaign in the Mediterranean theatre. It was soon brought home to hygiene officers that their energies had often to be directed largely towards civilian hygiene matters, otherwise the health of the troops under their care inevitably suffered.

It is not possible to prevent a good deal of close association between troops and civilians. Large numbers of the latter are employed by the armies in docks, depots, and workshops, and also as cooks and mess-waiters. Very many troops are billeted in houses, some of which are still occupied by adults and children. Regulations prohibiting contact with the local populace can only be partially enforced; this is also the case with regard to the use of eating-houses and the purchase of food and drink. As a consequence of this inability to segregate the military and civil populations, outbreaks of infectious disease often threatened to spread to the Allied armies. The diseases that caused chief concern were smallpox, typhoid, dysentery, diphtheria, venereal disease, and typhus, all of which had an epidemic incidence among civilians. Malaria came into this category when large civilian reservoirs of infection added to the risk to the troops operating in the area.

A great deal of the work of tackling these problems fell on the shoulders of Field Hygiene Section officers and Deputy Assistant Directors of Hygiene, especially in the battle zones. In the rear area, too, these officers did excellent work in full co-operation with the medical branches of the Allied Military Government and the Allied Control Commission. The energetic way in which they set about the task, under the most difficult conditions, often with the scantiest of assistance, has perhaps not been fully appreciated. It was a factor of no small import in the successful conclusion of the campaign.

Typhus was extremely prevalent in North Africa, Italy, and Yugoslavia. The dangers of the disease spreading to the troops, and the occurrence of severe outbreaks among them, were well appreciated. The number of cases that actually occurred was, however, negligible. The factors influencing this escape are discussed in this paper. History is full of examples of how this grimly dramatic disease has devastated armies in the field; the lay officer is thus deeply impressed by its dangers. Fuller

co-operation can generally be looked for from him than is the case with less "spectacular" diseases such as malaria, typhoid, and dysentery. It is a matter for surmise whether, if equal collaboration had been forthcoming in the prevention of those other diseases, a similar degree of success would not have been achieved and an enormous loss of man-power avoided.

NORTH AFRICA

The projected Allied landing in North Africa in November, 1942, was a closely kept secret, which undoubtedly contributed to its initial success. Senior hygiene staff officers were not admitted to the preliminary discussions (although many junior "A" and "Q" officers were), and it was, to them, an unknown venture, both geographically and epidemiologically. This omission was unfortunate and unnecessary. It served to confirm the fact that the role of the Army hygiene organization as an essential factor in the success of a campaign had not yet been properly appreciated. Indeed, it was only the stark reality of heavy casualty rates from preventable sickness that, in the months and years to come, gradually brought the lesson home.

Anti-typhus measures in the British Force consisted in the provision of adequate quantities of anti-louse powder (A.L.63) and the inclusion of portable disinfectors as part of the equipment of regimental medical officers, field hygiene sections, and mobile bath units. The portable apparatus is capable of dealing with nearly 100,000 blankets or 13,000 sets of clothing per division each week. Inoculation with anti-typhus vaccine (Cox's) was confined to medical staff officers. Before embarkation, and particularly during the sea voyage after the destination had been made known, propaganda talks to officers and men were given as often as possible. Some at least of this and previous hygiene education fell on responsive ears, as was shown by the fact that some units had a much lower sick rate than others exposed to the same conditions.

As soon as possible after landing a visit was paid to the Chief Public Health Officer for Algeria. Dr. Grenouilleau was very helpful throughout. He placed at our disposal all available epidemiological data, giving advice on malaria control and other public health problems. Dr. Émile Sergeant and the other officers of the Pasteur Institute, Algiers, were also extremely co-operative. It was only occasionally that the political tension which was such an unfortunate feature of the Algerian venture affected the happy relations between British and French doctors. There were, however, a few instances in which doctors with strong Vichy sympathies failed to co-operate: their attitude of prevarication and indifference was in marked contrast to that of their colleagues.

Incidence of Civilian Typhus

It was at once evident that a large-scale typhus epidemic had swept through Algeria during the previous four years. There were indications that it would increase in intensity during the winter of 1942 and the spring of 1943. The statistics given by Dr. Grenouilleau were as follows:

Number of Typhus Cases, Algeria

Oct., 1939 to Sept., 1940	Arabs, 2,016; Europeans, 37
" 1940 " " 1941	" 9,767; " 509
" 1941 " " 1942	" 35,059; " 2,837

He was of the opinion that this did not represent the true incidence, and the actual numbers were at least six times the

recorded. The estimated numbers during the three previous years were: 1939-40, 11,000; 1940-1, 55,000; 1941-2, 300,000. Graphs showed that each year the number of cases rose rapidly until May/June. A sharp fall did not begin until July/August. The continuance of the epidemic during the hot Algerian summer seemed to be very significant.

The death rate was not easy to compute in the case of Arabs. Among cases in hospital it was 29% in Europeans of all ages and 22% in Arabs. During 1942, 700 Europeans and 40,000 Arabs died of typhus in Algeria. There was also information that typhus was present in Tunisia, but exact details as to the extent of this outbreak were not obtained until much later.

Control measures were not put into operation by the French authorities until late in the year 1941. These consisted of:

- (a) Systematic vaccination, using chiefly living vaccines.
- (b) Restriction of movement.
- (c) Rounding up of destitute and infested people, and delousing them.
- (d) Surveying affected communities and paying attention to the people in prisons and hospitals, the members of the Youth Movement (*Chantier de Jeunesse*), etc.

Of these measures vaccination was considered to be the most important. It is probable that measures *b* and *c* did not operate to any great extent. The Arab population had an extremely high infestation rate. The depredations of the Italian and German Armistice Commissions had resulted in a severe shortage of food; soap and fuel were almost unobtainable. The Arab population was literally in rags, and material for clothing was completely wanting. Disinfestation apparatus was very limited even in the port of Algiers. The cleansing of the infested Arab population must therefore have been a problem incapable of solution with the means at the disposal of the French authorities.

Vaccination against Typhus

This was begun at the end of 1941. The living vaccine of Blanc and Baltazard was used for the Arab population alone. Two million doses were distributed. Blanc vaccine consists of the dried faeces of fleas infected with murine typhus, dissolved at the time of inoculation in a bile-salt solution—1 mg. in 100 ml. It is given in a single dose of 1 ml. Inoculation must be completed in half an hour. After that time the vaccine increases in virulence appreciably. Those vaccinated first do not, therefore, receive the same type of dose as those injected at the end. It was stated that ill effects were rare, but that up to 5 or 6% got murine typhus (as compared with Blanc's figure of 1.5%). All the murine cases recovered. The vaccine was said to be an excellent collective prophylactic but not an ideal individual one. It was not contended that all persons receiving the "virus-vaccin" escaped typhus—many had unmodified attacks—but mass vaccination *did* "break the chain of infection," and it caused "local extinction of the epidemic." A large proportion of the people in a community must be inoculated; 60% of these acquire a "durable and solid immunity." The aged and those with cardiac, renal, or pulmonary disease were excluded. The value of a one-shot method of vaccinating an Arab population is obvious, and from the records shown by Dr. Grenouilleau the results were excellent.

Mass vaccination was always followed by a dramatic fall in typhus cases—particularly so in communities where cases were on the increase. The morbidity rate fell in April, whereas it persisted in control unvaccinated towns until the end of June. In Tebessa, for example, a widespread outbreak was extinguished after 95% of the Arab population had been vaccinated. Similar results were obtained in the native quarter of Algiers (the Kasbah) and many other places where the epidemic was spreading with alarming rapidity.

It was noticeable that during 1943 practically no cases of typhus occurred in towns where vaccination had been carried out during the previous two years. This was of importance to us, for troops stationed there ran no risk.

The killed vaccine of Durand and Giroud was also used, but only to a limited extent. Owing to shortage of materials, such as phials, ampoules, and packing, only 71,000 doses could be distributed between the end of 1941 and the time of the Allied occupation. When the necessary requirements were made available the Pasteur Institute at Algiers was able to produce this

vaccine in very large quantities. A large amount was obtained by us for use in Algeria, and also Italy and Yugoslavia. Prior to November, 1942, doctors and other exposed persons, such as policemen and railway and prison employees, were the only groups given this vaccine. It is of interest to record that the Algerian doctors did not regard this vaccine with enthusiasm; many were frankly sceptical. (This was also the case in Naples at a later date, when Cox's vaccine was made available to members of the Italian medical and nursing professions and the response in both groups was poor.) At that time 29 Algerian doctors contracted typhus. Eleven of these had been vaccinated; they all recovered. Of 18 who were unvaccinated 13 died. There were many cases of typhus among the 71,000 vaccinated, but I was informed that there were no deaths. These vaccines are prepared from mouse or rabbit lungs, and are formal-killed. Three doses are given at weekly intervals—0.5 ml., 1 ml., and 1.5 ml. A febrile reaction follows the first injection in about 40% of cases.

By the end of 1942 two millions out of a population of eight to nine millions had been inoculated, most of them with the living vaccine of Blanc. Since the vaccine gives immunity in only about 60% of cases this meant that 1,200,000 people were immunized. This was a magnificent achievement in view of the enormous difficulties to be overcome under wartime conditions.

Position of the Allied Armies

Mention has already been made of the preparedness of the British Army against a typhus risk. The American Forces were all inoculated, but for the first few months British troops were entirely unprotected. Conditions were favourable for the spreading of typhus to the armies: the weather on the Atlas plateau was cold, bathing and laundry arrangements were difficult, and soap and fuel were not plentiful; the war was mobile, and troops occupied or passed through overcrowded Arab villages; the natives thronged railway stations and staging points; Arabs were recruited for labour companies for employment in docks and railway stations; a good deal of casual labour was also engaged. Billeting in Arab houses, too, proved a great danger. One small unit had 90 cases of heavy louse infestation after a short period of billeting in some of these houses.

The first preventive action taken was the publication of routine orders pointing out the typhus danger and the risks attendant on close contact with Arabs. The regular use of A.L.63 powder, by hand-dusting, was ordered in the case of all troops in affected areas, and those, such as dock and railway workers, military and traffic police, who were exposed to special risks.

Propaganda was intensified. Roadside notices, painted by field hygiene sections, were affixed to the walls of houses in towns, and to telegraph poles along the main highways. Wood and paint were in theory unobtainable, but the signs appeared notwithstanding. The road from Algiers to the Tunisian frontier presented a strange sight: along its 500 miles of tortuous length were to be seen thousands of notices giving warning of the dangers of typhus, malaria, dysentery, and venereal disease. Some were crude and couched in terms that offended the fastidious, others were clever and well executed, but the propaganda value of all was undoubted. These signs played a leading part in the campaign against infection. The wooden signs were regularly torn down by the Arabs for use as firewood. They required constant replacement, and even when corrugated-iron squares superseded them these also disappeared. The Services newspaper, the *Union Jack*, which was started later, was always willing to give us some of its limited space for propaganda. This took the shape of leading articles, daily "health hints," and cartoons. Posters were produced by many formations, and some of the ideas were excellent. Until such time as we had facilities for printing, duplicating machines of the signal services were used. Many hundreds of coloured posters were produced in this way. Films on the louse were shown to base troops, but there were few projectors. The Royal Navy helped us in this. Civilian apparatus was also borrowed, and even the regimental depot of the Zouave regiment was able to lend us a projector. Lectures and talks by hygiene and regimental officers were given whenever possible, and courses of instruction were started

by the hygiene sections. Stress has been laid on the propaganda aspect of prevention because it is believed that this played a conspicuous part in the prevention of typhus and other diseases.

Orders were issued concerning personal cleanliness and bathing; regimental bath discipline was closely watched, and regular medical inspection of all troops insisted upon. A large number of shower-baths and Serbian barrel disinfestors were improvised and distributed by the hygiene sections. Although authority was given for the triplication of portable disinfestors, the supply position never permitted this to be carried out except to a limited extent.

Native Labour Companies

The decision to form these companies imposed heavy additional tasks on the overworked hygiene section staffs. All the recruits were heavily infested, and they were a dangerous potential source of typhus. All were bathed, disinfested, and examined before being drafted away. There were many practical and administrative difficulties, and the keenest supervision was necessary. For instance, the Arab is loath to part with his turban. But since the head louse was a possible source of danger, he could not be allowed to retain it unless it had passed through the disinfestor. These and many other problems were overcome. In view of the typhus danger, it was decided to inoculate all the recruits. The only vaccine procurable in any quantity was the living vaccine of Blanc and Baltazard. This was used in many thousands of doses with no serious sequelae; a number of febrile reactions occurred but no definite cases of typhus. There was regular medical inspection of these labourers, and A.L.63 powder was used by them periodically. Casual Arab labour was also a problem. These men lived in their own homes, and it was impossible to keep them free from infestation. Cases of typhus occurred in many of these workers. In one town occupied by a large number of troops the French authorities would not admit these cases to the local hospital. Since it was essential to isolate them, the A.D.M.S. took over a building in the town, which was staffed with the help of French Red Cross nurses. The cases were admitted there under the care of an Arab doctor. This doctor worked with a will throughout, and gave us all the assistance in his power. In this town the French health officer was not co-operative; attempts to get him replaced were unavailing.

French and Arab physicians suggested many different methods of treatment. The French favoured the administration of massive doses of NaCl. This was found to be ineffective when tried on British cases. The turpentine blister was strongly advocated by the Arabs, and remarkable successes were attributed to its use. I was assured by an Arab physician that out of 71 cases so treated 62 developed a fixation abscess and recovered. Nine did not develop abscesses, and five of these died. The four who recovered were stated to have produced abscesses "spontaneously as a complication." British Army cases were not given this treatment.

Lethane belts were available in fairly large quantity, but they were never found to be practicable for use, even by natives, in the hot weather; they were therefore seldom employed in Algeria or Italy.

Typhus in the British Forces

There were about 40 cases of typhus in 1943, but at least six of these were not louse-borne (see Table). Many of the

Table showing Typhus Cases in the British Forces

		Sicily	N Africa	Italy	Total	Deaths
1943	Louse-borne ..	—	36	3	39	
	Other forms ..	—	6	5	11	
	Total ..	—	42	8	50	8
1944	Louse-borne ..	1	0	2	3	
	Other forms ..	1	4	7	12	
	Total ..	2	4	9	15	3

cases were brought into association with Arabs in the course of their work, but in others all contact with natives was denied.

Only two were found to be lousy or showed evidence of louse bites on admission to hospital. Bath discipline was good in all the units concerned, but A.L.63 was often being used haphazardly or not at all. Two officers were affected. Both had lived in premises occupied by Arabs a short time before. Prompt civilian notification records were not being received in some districts; the M.O.H. of an area from which many of our cases came professed little knowledge of a severe Arab outbreak near the town concerned.

One of the British cases was fully inoculated; three had received one injection, 60, 26, and 22 days before the onset respectively. All of these recovered. Records of 25 cases occurring between January and April, all louse-borne, show the death rate to have been 32%. The cases were severe in type and clinically suggestive of classical typhus. Rashes were typical and constant. The Weil-Felix reaction was consistently useful in diagnosis, but agglutination was not usually appreciable until the end of the first week. Between the 7th and 21st days the titre rose from 1:250 to 1:10,000. On an average our cases were diagnosed on the 10th day of illness. Deafness was a noticeable symptom in most of them.

A case of murine typhus occurred in a member of the R.A.F. He was stationed in an isolated post. The local French doctor prevailed upon him to have an injection of the living vaccine of Blanc. He became ill on the 12th day, but not seriously. The illness was suggestive of mild enteric, but agglutination tests were negative. His rash was scanty, and not typical of typhus. Profuse sweating was a marked feature. His case was diagnosed as murine typhus in retrospect, as a result of Weil-Felix agglutination. Later in the year, and the following year in Italy, there were a few cases of *fièvre boutonneuse*, most of which were probably infected in Sicily or Southern Italy. About 20 cases occurred among American troops, none of which is said to have been fatal. It is significant that all the Americans were inoculated with Cox's vaccine.

Many Algerian doctors subscribed to the belief that air-borne transmission by way of the mouth or conjunctivae was a not uncommon source of infection. In my experience there was little evidence to support this theory, though conditions were very favourable for the spread of a disease which is capable of transmission by this means. The streets of towns and villages occupied by troops were generally dense with Arabs, whose robes were billowed out by the breezes of the windy Atlas plateau. The Arab delouses himself by hand-picking the lice and dropping them alive to the ground. In the case of children the disease may be symptomless, and many ambulatory cases occur; these nevertheless infect the louse. The air of the dusty Algerian highways must have been well charged with dried louse faeces! Had transmission in this way been even remotely possible the uninoculated British Forces must have suffered heavily.

TUNISIA

Details as to the prevalence of typhus in Tunisia were not at first obtainable, but it was understood that the Algerian outbreak had also affected Tunisia. It soon became evident that this was a fact. When official returns from "Free Tunisia" were furnished they showed 200 reported cases during the last week in February, about 500 in March, and 300 in the first ten days of April. These figures represented only a part of the actual total. A few First Army troops were infected in Tunisia. Vaccination and disinfestation of the Arabs were begun. This was a difficult and dangerous undertaking in the forward areas, frequently interrupted by Axis dive-bombers and often concluded in slit-trenches. Field hygiene sections and civilian doctors both played a leading part in this work.

After the fall of Tunis it was learned that many cases had occurred in the Axis Armies; the Germans, it was said, suffered to a greater degree than the Italians, which is surprising. Anti-typhus inoculation (? Cox type) was started in the German Army, but no Italian units were inoculated. At least six prisoners of war developed typhus after capture. There was a grave danger of this, owing to the high infestation rate in the German and Italian prisoners: 40% of German and nearly 80% of Italian prisoners were lousy. Bathing and delousing schemes were put into operation at once, but the disorganization following such a massive capitulation, and the shortage of

water, fuel, and equipment, made it a herculean task. It was a blessing that the typhus season was well advanced by this time. The weather was hot, and the prisoners wore the minimum of clothing. As organized prisoner-of-war cages were established, and satisfactory arrangements were made, the danger passed.

Relapsing Fever

The presence of this disease in North Africa has a bearing on this discussion. Relapsing fever is endemic in Algeria, and during 1943 twelve British troops were affected. The disease increased to epidemic form at the end of 1944 and early in 1945. It spread quickly from Algeria to Tunisia, where 1,746 cases occurred during the last two weeks of February. In January, 1945, there were 6,000, and in February 7,400 cases, including 80 weekly in a civil prison. It was reported that the epidemic was assuming enormous proportions in the Saharan towns and those of the Tel plateau. This disease is spread in epidemic form by lice; it is thus evident that the native infestation rate was still very great. One would therefore have expected the incidence of typhus to remain at a high level. The fact that a large number of the Arabs had already had typhus is not sufficient to account for the dramatic fall in morbidity in 1943, 1944, and 1945 in a heavily infested and economically depressed people. Vaccination was therefore effective despite the fact that infestation remained.

Reasons for the Low Incidence of Typhus among Allied Troops

Of first importance was the fall in the number of Arab cases in 1943, when the anticipated increase did not occur. This was probably the result of the mass vaccination scheme of the previous two years. Vaccination was continued in 1943, when notices appeared in the towns and in the Press stating that it was compulsory. All persons between 10 and 70 years were required to present themselves for inoculation; fines ranging from 100 to 1,000 francs were payable in default.

The fear of typhus, stimulated by intensive propaganda, made a great impression on the troops, and was a potent reason for our escape. The military police, despite their numerous other commitments, gave great help in enforcing orders and in ensuring that "out of bounds" notices were not ignored. Bath discipline was good. A.L.63 powder, although often used carelessly and irregularly, was extremely effective. The wide dispersion of units and the careful selection of camps probably helped also. Inoculation was not a factor of any importance, for until the late spring and summer the number protected was negligible.

(Part II will appear in next week's issue.)

DUODENAL ULCERATION: A GASTROSCOPIC STUDY OF THE GASTRIC MUCOSA AND ITS SURGICAL SIGNIFICANCE

BY

HARRY FREEMAN, F.R.C.S.

Surgical Registrar, National Temperance Hospital; Surgeon, E.M.S.; Assoc. Lecturer on Surgery, North-East London Postgraduate College

The problems associated with the surgical treatment of duodenal ulceration and of some of the complications which follow in its wake in a very large proportion of cases have for many years occupied the mind of the profession, yet it seems that little universal progress has been made in the past quarter of a century in the treatment of a disease which still produces much physical and mental suffering in the individual and much economic loss to the community at large. With these problems in mind, I have made an intensive gastroscopic study of the mucosa of the stomach in the presence of duodenal ulceration, as well as a study of the mucosa in cases following operations for this malady, with a view to eliciting the relationship of the anatomy and physiology of the morbid mucosa and its transmutation as a result of surgical treatment, and its bearing upon the subsequent condition of the patient.

A close study of the aetiological factors said to be associated with duodenal ulceration reveals that a definite relationship

exists between this pathology and a deranged physiology of the stomach and, indeed, that of the greater part of the alimentary tract. It would therefore be as well to give consideration to the individual who presents himself with established ulceration or, on the other hand, merely with symptoms suggesting the outlines of the image, which, as time goes on, gradually evolves itself into the completed picture of a subject with duodenal ulceration. He is an extremely sensitive and hyper-irritable type, in a constant state of nervous tension and emotional instability; vasomotor disturbances are present and, above all, he is stomach-conscious. These nervous influences play a very important part by virtue of the fact that they are referred to his alimentary tract and can be readily demonstrated by the radiologist during an x-ray examination after a barium meal. They further manifest themselves in certain spastic phenomena, of which spasm of the pylorus and duodenum and of the descending colon are typical examples. So very often little importance is attached to these phenomena at the time of the examination or, indeed, to any subsequent report of these radiological findings or their possible interpretation. When spasm occurs in a vascular structure a temporary impairment of the blood supply to the part concerned results, with local loss of viability. These changes commonly occur in the duodenum, and the local loss of viability produces a condition in which the mucosa becomes vulnerable to injury by contact with irritant or insufficiently digested food; if in addition local necrosis occurs it is not difficult to visualize the possibility of ulceration in the presence of a high acid-pepsin content of the gastric juice. The duodenum houses a mechanism which is stimulated by the presence of food into liberating the hormone enterogastrone, which itself controls gastric secretion and peristalsis. When spasm and local loss of viability occur this mechanism fails, and the normal gastric function is now replaced by hypermotility and rapid emptying of insufficiently digested food, which may damage the vulnerable duodenal mucosa; such injury is aggravated by the high acid secretion which is a constant factor in the type of individual described.

The surgeon is frequently called upon to deal with a perforation of or haemorrhage from a peptic ulcer, but a precise history of gastric symptoms is very often lacking in these examples of "silent ulcer"; later inquiry into the health and habits of these patients reveals that the various nervous phenomena did however exist, and even at an early age a test-meal examination would show a marked increase in the amount and acid content of the gastric juice.

Normal Gastric Mucosa

As seen through the gastroscope the gastric mucosa consists of a thick transparent smooth orange-red lining thrown into many folds throughout the greater part of the stomach. These folds are tortuous in some areas and resemble the convolutions of the cerebral cortex. The folds can be straightened out or made to disappear altogether when the stomach is distended with air, and this is an important point in differentiating the normal from the hyperplastic type of mucosa, in which the folds in

FIG. 1.—Normal mucosa on anterior wall (left of picture) and greater curvature.

FIG. 2.—Normal mucosa on posterior wall and greater curvature with little inflation.

certain areas remain tortuous even with full inflation. The smoothest part of the mucosa is found along the lesser curvature of the stomach, but occasionally one or two very thin parallel folds may be seen here. Both the greater curvature and the posterior wall of the stomach present a network of many folds, parallel and slightly tortuous in the former situation, but much

more tortuous and thicker on the posterior wall (Figs. 1 and 2). A few thin parallel folds are present in the pyloric antrum, but these readily disappear with very little inflation and are not often observed. The surface of the mucosa is very smooth and glistening in all areas of the stomach; many high lights are sprinkled over the gastroscopic picture, and these are due to the diffused glow of the lamp over the moist surface. When secretion is excessive the number of high lights is correspondingly increased; if gastritis is present and some of the ducts become blocked, secretion into the cavity of the stomach is diminished and the number of high lights seen is very small, or they may be absent altogether.

Gastric Mucosa in the Presence of Duodenal Ulcer

In a series of 50 gastroscopic examinations of cases of duodenal ulceration I found that in 76% the mucosa was of the hyperplastic type; the mucosa of the remainder varied a little in the development of the folds, but was considered to be within normal limits. This hyperplasia manifests itself in the formation of very many crowded, thickened, and extremely tortuous folds which cannot be straightened out even after full inflation of the stomach, and which certainly cannot be made to disappear. These crowded folds are most marked upon the posterior wall of the stomach; they develop along the greater curvature and may replace the straight folds normally present on the anterior wall. There is thus found a more or less generalized hyperplasia or hypertrophy of the gastric mucosa, with an increased complement of glandular elements which is capable of producing an excessive secretion of a hyper-acid juice.

Gastric Mucosa in Non-obstructive Cases

In addition to generalized hyperplasia gastritis may be present, and this manifests itself by areas of oedematous folds and scattered patches of viscid adherent greyish-yellow secretion, which occupies chiefly the valleys between these folds; high lights are markedly diminished over these areas of superficial gastritis, and the mucosa is vulnerable and may readily bleed during the examination. Gastritis is not necessarily an accompaniment of duodenal ulceration, but, when present, disappears with adequate medical treatment although the ulcer itself may still remain. When an ulcer has healed under a medical regime the hyperplastic nature of the mucosa does not change. Sometimes a gastric ulcer may also be present in addition to the duodenal ulcer, and I have observed three such cases in the series. The incidence of this phenomenon varies, and has no relation to the mucosa of the stomach; Carey and Ylvisaker (1942) have reported as many as 9 out of a series of 70 cases of duodenal ulceration in which gastric ulcer was also present.

Mucosa in Obstructive Cases

It is not sufficiently appreciated that obstructive symptoms following upon ulceration may be entirely due to local oedema and spasm of the pylorus. First, this is borne out by the fact that cases in which the radiologist reports a delayed emptying of the stomach will improve with adequate medical treatment and a little patience if the cause is essentially one of oedema and spasm, and it is always worth while repeating the x-ray examination two or three times after intervals of three weeks. Secondly, a large number of these cases are operated upon following the report of obstruction, and a gastro-enterostomy performed. When these patients are subsequently seen because of a recurrence of symptoms, and a fresh x-ray examination is carried out, it may surprise the surgeon when the radiologist reports that "a large portion of the meal passes through the pylorus." Obviously, then, these were cases where the obstruction was non-fibrous and purely transient.

The condition of the mucosa in these obstructive cases varies considerably; viscid adherent secretion and a dulling of or granular change in the surface of the mucosa constantly take place over large areas, but these mucosal phenomena disappear when the obstruction is relieved. If, however, obstruction has periodically occurred, or if the obstruction is of the fibrous variety and progressive, the changes seen in the mucosa are very much more marked: not only is there an increase of the pathological secretion but the folds are very oedematous and eventually become broken up into raised nodular segments which resemble pavement or cobble stones closely packed together.

These changes occur in the valleys between the folds as well as on the folds themselves. This condition is sometimes known by the name of "chronic hypertrophic gastritis," and must not be confused with simple hyperplasia of the mucosa. Occasionally the pyloric antrum becomes the seat of these changes, but only after the onset of true fibrous obstruction.

Fifty Cases of Duodenal Ulcer

Hyperplastic mucosa	38 cases	76%
Hyperplasia with no other changes	14 cases	38%
and superficial gastritis	15	30%
" " nodular gastritis	7	18%
" " antral gastritis	2	5%
Normal mucosa	12 cases	24%
Superficial gastritis	3 cases	25%

Post-operative Recurrence of Symptoms

It is not my intention to enumerate the many causes of recurrence of symptoms after operation for duodenal ulceration. Patients often present themselves with symptoms similar to those for which they were operated upon. These symptoms may be due to inflammatory changes which were present in the gastric mucosa before operation, and which persist after operation. It may be well worth while to gastroscopically examine the patient before any operation is contemplated, in order to visualize the gastric mucosa and its condition. With the failure of the short-circuit operation in many instances—for this had become a disease in itself rather than an intended cure—more radical measures were resorted to. Although advocates of gastro-duodenectomy and partial gastrectomy have shown individually results which should be very convincing, yet it is a fact that these formidable procedures still have a high mortality in some hands, and even a great degree of morbidity in others. Stomal ulceration may occur after partial gastrectomy (Fig. 3), and I have observed such cases; doubtless more

Fig. 3.—Stomal ulcer 18 months after partial gastrectomy.

cases will be recorded as gastroscopic examinations are increased. Inflammatory changes in the mucosa of the gastric stump must also be included in this category, so that this operation is not altogether a solution for a very important problem in surgery. In addition, the creation of a very grossly distorted anatomy and a grossly deranged physiological function of the stomach does not seem rational in the quest for a cure of a condition the aetiology of which is still unknown. The initial success of partial gastrectomy may be hailed by both patient and surgeon, but the morbidity is not quite appreciated because with a recurrence of symptoms a large number of these patients change their hospital. Even at the best the patient fails to regain weight or to admit of being comfortable; he remains stomach-conscious.

To ensure success of any medical regime in the treatment of duodenal ulceration it is essential that the amount of gastric juice and the degree of acidity be considerably reduced; whichever method achieves its object in healing the ulcer, the lowered acid content of the gastric juice is but a passing phase. When surgical measures are indicated it is desirable not only to obtain a physiological reduction in the activity of the stomach but to ensure that this reduction is permanent or at least prolonged, because very real risks of complications ensue on any surgical procedure if the original high acidity remains. The high-acid-secreting hyperplastic type of mucosa is very liable to stomal ulceration after the operation of gastro-enterostomy, and indeed after any surgical procedure if the high acidity is allowed to remain. Of those cases of stomal ulcer observed by me in the course of gastroscopic examinations, 65% occurred in the

presence of hyperplasia of the gastric mucosa. This operation alone should clearly be avoided when the mucosa of the stomach is of this type. Bearing this all-important problem in mind, it may be more rational to adopt a simpler and apparently surer method of attaining what the more formidable methods have failed to do, and in this respect we have seen some excellent results which have been obtained by Somervell (1942), who advocates ligation of a large proportion of the arteries which supply the stomach. The hypersecretion and acidity are immediately reduced, and remain so for a very long time.

In order to evaluate the results of ligation, I have observed the changes in the mucosa of the stomach in which I myself carried out this operation. It was seen that the mucosa in simple hyperplasia had undergone a marked transmutation from the hyperplastic state to one which could be considered as being well within normal limits. These cases were gastroscopied before (Fig. 4) and six months after (Fig. 5) gastric arterial ligation

FIG. 4.—Case of duodenal ulceration: hyperplastic mucosa with crowded folds.

FIG. 5.—Same case as in Fig. 4 six months after arterial ligation. Note regression of folds.

had been performed; the folds were now far less crowded and tortuous, and inflation straightened many of them. In the presence of fibrous obstruction, posterior gastro-enterostomy was performed in addition to ligation, but where nodular changes in the mucosa had occurred these remained unchanged after an interval of six months. It is possible that earlier treatment would have prevented these nodular changes from developing.

Although these conclusions have been drawn from a limited number of cases, it is possible to correlate the reduction of gastric acidity with the changes in the nature of the mucosa following upon ligation. This regression must be part of an inherent power peculiar to the mucosa, in which reverse changes—namely, regeneration under certain conditions—may also take

Chart of a case of duodenal ulcer.

place: the thinned atrophic mucosa associated with pernicious anaemia will regenerate and regain its thickness with suitable liver therapy, and the reappearance of folds will produce a picture which is difficult to distinguish from the normal.

It is thus reasonable to conclude that there is sufficient justification to look upon these more conservative surgical measures in the treatment of duodenal ulceration as heralding a tremen-

dous field of opportunity for further work in this direction. The clinical and physiological results, as well as the gastroscopic findings following upon arterial ligation alone, or in conjunction with gastro-enterostomy (see accompanying Chart of a case) if fibrous obstruction is present, are such that even the most sceptical would agree on the value of, and the desirability for pursuing, measures less drastic than partial gastrectomy if these measures attain their object in reducing the high acid content of the gastric secretion without a gross distortion of the anatomy and physiology of the stomach.

THEORY AND NOMENCLATURE OF THE Rh TYPES, SUBTYPES, AND GENOTYPES

BY

ALEXANDER S. WIENER, M.D., F.A.C.P.

The Rh blood types have been the subject of many communications to the *Journal*. The purpose of this article is to correct several statements which have appeared in some of these reports, in order to prevent widespread confusion in an already highly complicated subject.

In a recent letter to *Nature* Fisher and Race state: "The notation has been frequently changed, and we feel that only a notation which designates unambiguously the antibodies, the genes or gene-complexes, and the antigens with which these antibodies react, can avoid widespread confusion." With the latter part of this statement I agree wholeheartedly, but would add that the notations should be made as simple as possible to favour their fluent use, both orally and in print, by medical men and geneticists, in order to further the work in the field. This has been my aim ever since my first work^{1,2} on the Rh types was done in 1940-2, at which time only the anti-Rh₀ and anti-Rh' agglutinins were available. Changes were made only when advances in knowledge, such as the discovery of the agglutinin anti-Rh" and the Hr agglutinins, made slight revisions and additions to the nomenclature necessary. As explained by me⁴ in a historical article presented before the New York Academy of Sciences, and also by Taylor and Race,⁵ these new findings did not change our previous results but merely added to them, and in revising the nomenclature as many of the old names as possible were always retained. The new findings required the creation of some new names, but at all times the principle of keeping the designations as simple as possible and unambiguous guided my actions. Some confusion has been created by the attempt of other workers⁶ to introduce numbered nomenclatures which fail to take into account the established genetic and serologic knowledge of the subject. Considering only the four agglutinins—anti-Rh', anti-Rh", anti-Rh₀, and anti-Hr—4×3×2×1 or 24 such possible numberings can be devised, so if the use of numbers were encouraged a far worse confusion would result than the Moss-Jansky jumble. Luckily, such numbered systems have found favour only in the laboratories of their originators, and so have caused little or no harm to date.

The letter by Fisher and Race continues: "Six of the gene designations here adopted are due to Wiener, but for the antibodies his notation seems arbitrary. While Cappell's names, such as anti-C, anti-D, anti-E, and anti-c, are unambiguous, Wiener's do not seem satisfactory, since, for example, the 85% reacting serum is called anti-Rh₀ whereas besides Rh₀ it reacts with the genes Rh₁, Rh₂, and Rh₃." As can be seen from Table I.

also states that the relative frequency of gene R'' to gene R_1 as compared with R' to R_1 indicates that his mythical gene locus c lies between d and e . However, these statements are based entirely on the findings in England and disregard the findings in other countries. In America, for example, the relative frequency of R' to R'' is reversed, while in negroes the frequency of r^0 (42.1%) is quite different from the sum of R' (2.7%) and R'' (none found).¹⁷ As a result Fisher's theory leads to a contradiction. In my opinion a much more plausible explanation is that the genes r^0 , R' , and R'' arose by mutation. Thus the high frequency of gene r^0 and of the intermediate R genes, as well as the intermediate gene A_1 ,² suggests that the peculiar distribution among negroes is due to a higher mutation rate in this race.

The argument that the discovery of the so-called c^w factor¹⁸ supports Fisher's theory does not seem correct, because this factor appears to have the characteristic predicted by me^{12} for factor Rh'' .

In this connexion I should like to point to a recent attempt¹⁹ to develop an elaborate theory of inheritance of the four blood groups by means of four gene couplets. On the basis of this theory, Myslivec derives formulae for the gene frequencies involving the square root of the difference 0-2 AB. Since populations exist in this world where the frequency of group O is less than twice the frequency of group AB, the theory leads to an obvious contradiction.

In conclusion I should like to take this opportunity to answer the rather academic attack²⁰ on my use²¹ of the term "conglutination" in connexion with the Rh antibody reactions. Recent findings²² have all sought to justify my use of this term. The term "co-agglutination," used by other workers, applies to a phenomenon obviously identical with mixed agglutination, and one would expect this to occur in conglutination where the second stage is non-specific.²³ In agglutination, involving bivalent antibodies, where the second stage is specific, co-ideas and findings concerning univalent (blocking antibodies or agglutinins) and bivalent antibodies (agglutinins) have led me to the theory²⁴ that erythroblastosis foetalis actually comprises three separate entities instead of a single disease. According to my proposed nomenclature, these three entities are as follows: (1) Congenital haemolytic disease (with anaemia and hydrops), usually due to univalent Rh antibodies; (2) icterus gravis with kernicterus, usually due to bivalent Rh antibodies; and (3) icterus praecox (formerly confused with "physiologic" icterus, usually due to A-B sensitization. Further details will be given in papers now in the press and in preparation.

From a world starved of all types of scientific and surgical equipment by six years of war, inquiries and orders are pouring into Britain for products in this field. To cope with this new demand, a group of leading manufacturers announce the formation of a new company, "SCIEX" (Scientific Exports (Great Britain) Ltd.), with offices at Buckingham House, Buckingham Street, London, W.C.2. Their plans include group selling in overseas markets by a wide development of the existing agency organization of individual members. New agents are also being appointed in territories where member companies had no previous export business.

THE Rh FACTOR AND HEPATOMEGALY AND SPLENOMEGALY IN CHILDREN AND ADOLESCENTS

BY

R. J. DRUMMOND, M.R.C.S., L.R.C.P.

Transfusion Officer, National Blood Transfusion Service,
Wales Region

AND

A. G. WATKINS, M.D., F.R.C.P.

Physician in Charge of Children's Department,
Cardiff Royal Infirmary

Infants affected with congenital haemolytic disease may sustain damage to liver or spleen, or both, as manifested by jaundice and hepatomegaly, or splenomegaly, during early infancy. It seemed, therefore, of interest to apply Rh factor investigations in families in which there were children or adolescents suffering from enlargement of liver or spleen, on the ground that the aforementioned damage might become manifest in childhood by enlargement of these organs. Accordingly, three families were investigated and data concerning them are given below. The affected children were referred for diagnosis to the paediatric department of the Cardiff Royal Infirmary. Rh factor investigations were carried out in the laboratory of the Welsh Regional Transfusion Service. In two of the three families rhesus-immunization of the mothers was proved, but in the third family this was definitely excluded. The method of proof was the biological test, as the usual *in vitro* tests failed to reveal Rh iso-antibodies in the sera of the mothers. These cases are of much interest, since the affected children had enlargement of the liver or spleen, and such diagnoses as von Gierke's disease (glycogen disease), Gaucher's splenomegaly, Banti's disease, familial cirrhosis of the liver, etc., had been considered from time to time. Before giving an account of the families and investigations, the biological test may here be reviewed.

Oehlecker (1921, 1924) originally devised the biological test to determine whether blood was compatible for transfusion. The test was the rapid intravenous injection of 20 ml. of the proposed donor's blood, and a further similar quantity if after an interval of several minutes there were no symptoms. If the second injection caused no symptoms the donor's blood was regarded as compatible and its transfusion proceeded with. The donor's blood was considered incompatible if symptoms such as tingling, chill, nausea, etc., were caused by the small trial injection. This test, however, is not entirely reliable, because transfusion of incompatible blood may cause no symptoms (Drummond, 1944). Oehlecker's test, which in effect is simply a trial transfusion of blood, was subsequently adapted by Wiener, Wexler, and Gamrin (1944) for determining whether a particular individual had been previously sensitized to the Rh factor. It was known that *in vitro* tests might fail to demonstrate Rh agglutinins or blocking antibody in the sera of a small percentage of Rh-negative mothers who had had erythroblastotic infants, and in such cases the biological test was successfully used to demonstrate previous rhesus-immunization of the mother.

The biological test (see Wiener, Silverman, and Aronson, 1942) is carried out as follows: The mother to be investigated for previous immunization to the Rh factor is transfused with 50 ml. of fresh blood from a known Rh-positive donor. The ideal donor is the husband. The red cells of the donor must be compatible in the A-B-O system with the recipient's serum. Immediately before transfusion a 10-ml. sample of venous blood is taken from the mother with a clean, dry sterile syringe and divided between two tubes, one dry and the other containing 1 ml. of sodium citrate solution. One hour after the transfusion a further 10 ml. of the recipient's venous blood is taken and treated in the same way as the first sample. The serum and plasma of the pre- and post-transfusion samples of the recipient's blood are then compared. If the donor's blood is compatible the pre- and post-transfusion samples of the recipient's serum and plasma will be of the same colour—usually a pale straw colour. Hyperbilirubinaemia in the post-transfusion serum sample, along with its absence from the pre-transfusion serum sample, indicates that the donor's red cells are incompatible and have undergone rapid destruction in the recipient. When the biological test is positive the transfusion is usually, but not always, complicated by a febrile reaction with chill, rigor, etc. A cross-matching test by a reliable tube technique before transfusion should,

of course, have shown the donor's red cells to be compatible with the recipient's serum; it is a positive biological test which demonstrates the incompatibility. It has been pointed out by Mollison (1943) that even though an Rh-negative woman has, many years previously, been immunized to the Rh factor by bearing an Rh-positive foetus, and the Rh antibodies have long since disappeared from her serum, yet transfusion of Rh-positive blood will rapidly erode the Rh agglutinins, with consequent haemolysis of the donor's blood.

Case Report: First Family

Mrs. M., aged 47, had never had a blood transfusion and has had the following pregnancies:—First: 1923, male (Ll.); no history of jaundice—further data below. Second: 1925, female (Els.); normal. Third: 1927, male (Rbt.); no history of jaundice—further data below. Fourth: 1930, male (On.); normal. Fifth: 1933, female (Jy.); slight jaundice soon after birth, which persisted three days. Sixth: 1936, male (Gd.); died intensely jaundiced, aged 3 days. Seventh: 1939, male (Gl.); apparently normal. Eighth: 1940, female (Jan.); moderately jaundiced for a few days after birth; now apparently normal.

The first child (Ll.) weighed 9 lb. (4.08 kg.) at birth. When 3 years old he underwent inguinal herniotomy. His abdomen has always been large, and he did not walk until 3 years old. He was stated to be a trifle slow mentally, though he attended an ordinary school. He occasionally had loose pale stools. The third child (Rbt.) weighed 8½ lb. (3.85 kg.) at birth and had a similar history, including operation for hernia. Neither of these boys was ever jaundiced.

Both boys were referred for diagnosis in December, 1936, because of much-enlarged bellies since birth. The first (Ll.) was at this time 13 years old and was slightly stunted in growth: height 4 ft. 3½ in. (131 cm.) (normal for age, 4 ft. 10 in. or 147 cm.); weight, 5 st. 5 lb. (34 kg.) (normal for age, 6 st. or 38 kg.). When standing his abdomen was protuberant and there was slight genu valgum (Fig. 1). Some telangiectases were present on the limbs and face.

FIG. 1.—First family. Left to right: First child (Ll.) and third child (Rbt.), with liver areas mapped out. The boy standing on the right is the fourth child (On.), who was apparently normal.

The liver was grossly enlarged, its lower border being down to the level of the umbilicus, and smooth and firm on palpation. Spleen not palpable. Mentally he seemed normal, but the I.Q. was not estimated. The condition of the third child (Rbt.), then aged 9 years, was similar to that of Ll. but his liver was much larger, for its lower border was felt well below the umbilicus. The spleen was just palpable, and there was a well-marked genu valgum (Fig. 1). There was some degree of infantilism, his height being 3 ft. 7½ in. (111 cm.) (normal for age, 4 ft. 2 in. or 127 cm.) and weight 3 st. 10 lb. (23.6 kg.) (normal for age, 4 st. 2 lb. or 26.3 kg.). The parents were healthy, and the second, fourth, and fifth children (then aged respectively 11, 7, and 3 years) were normal, while the remaining sixth child had died, intensely jaundiced, when aged 3 days.

The Wassermann reactions of the parents and Ll. and Rbt. were negative. In both boys the red cells showed slight decreased fragility. The blood-sugar curve was normal in the case of Ll., but there was some delay in return to normal in the case of Rbt. A leucocyte-tolerance test on Ll. was normal. In both boys the van den Bergh test was negative. Each boy had a Hb of 74%; neither had a leucopenia. At this time (December, 1936) a diagnosis of familial cirrhosis of the liver was made. The other children were reported as normal at this time, and had no liver or splenic enlargement. Nothing further was heard of these two boys until 1945, when it was decided to apply Rh factor investigations. Ll. was examined in January, 1946; he was then of about average height, and his liver and spleen were no longer palpable. It will be noted that since the examination of the first and third children, in 1936, two further children (seventh and eighth, both Rh-positive) were born, the last of which had jaundice and recovered, whilst the other was apparently normal.

Rh Factor Investigations (July, 1945).—The mother was group O (IV) Rh-negative, and her serum contained neither Rh agglutinins nor blocking antibody. The Diamond-Abelson (1945) slide test was negative. Wiener's (1945) so-called conglutination test was difficult to interpret because of rouleaux formation, but the reaction was in all probability negative. The father was group B Rh+ (heterozygous). The children's groups were: Ll., O Rh+; Els., B Rh+; Rbt., B Rh+; On., B Rh+; Jy., O Rh-negative; Gl., O Rh+; Jan., O Rh+. On Jan. 14, 1946, the biological test was performed. The donor was Ll., the first child (group O Rh+). The father could not be the donor, as he was group B. The donor's red cells were compatible with the recipient's serum, and vice versa. Fifty ml. of the donor's blood was taken into 350 ml. of sodium citrate solution and at once transfused. The recipient, of phlegmatic temperament, became restless, anxious, and flushed when about half the blood had been transfused. Transfusion was completed in 30 minutes. The temperature was normal throughout, but an hour after transfusion it rose to 100.2° F. (37.9° C.). Thirty minutes after transfusion the recipient had a moderately severe rigor lasting 20 minutes. After five hours the patient's condition was normal. The pre-transfusion samples of the recipient's serum were a pale straw colour, but post-transfusion samples taken 1½ hours and 2½ hours after transfusion were deeply icteric. A catheter sample of urine collected an hour after transfusion was orange-coloured; there were no casts. A sample of the recipient's serum was collected on the 18th day after transfusion; it contained Rh agglutinins (anti-D) of titre 1/16. The Coombs *et al.* (1945a, 1945b) anti-human-globulin test, using a pre-transfusion sample of the mother's serum, gave a negative reaction.

Case Report: Second Family

Mrs. I., aged 42, had never had a blood transfusion and has had the following pregnancies:—First: 1934, male (Wm.); normal. Second: 1937, male; died of pertussis aged 5 weeks. Third: 1939, female (Pt.); full-term and normal at birth; no jaundice—further data below. Fourth: 1940, female; stillbirth at full term, but foetus was alive one week before delivery. Fifth: 1941, female; stillbirth at 28th week. Sixth: 1943, male; stillbirth at 26th week.

The third child (Pt.) was first seen in June, 1945, because of herpes zoster. Two years previously a school medical officer noted that she had an enlarged spleen. Apparently the child was not jaundiced at birth, nor at any time subsequently, but her abdomen had always been noticeably enlarged. Examination (in 1945) revealed a considerably enlarged spleen extending almost to the umbilicus. The liver also was enlarged, its lower border being 3 in. (7.6 cm.) below the costal margin (Fig. 2). The patient was a trifle undersized for her age. The haemoglobin was 76% and leucocytes 6,400. Fragility of red cells, normal. A tentative diagnosis of Banti's syndrome with cirrhosis of the liver was made. In January, 1946, the condition of the spleen and liver was unaltered. The parents are healthy, and the mother's Wassermann reaction is negative.

Rh Factor Investigations (July, 1945).—Mother, group O Rh-negative; no Rh agglutinins or blocking antibody detected in her serum. The third child (Pt.) was O Rh+, and her cells were not agglutinated by her mother's serum. Husband, O Rh+. First child (Wm.), O Rh+. The Diamond-Abelson (1945) slide test was negative, but the so-called conglutination test of Wiener (1945) gave a positive reaction.

It was decided to obtain more certain evidence of rhesus-immunization of the mother by applying the biological test. The husband of Mrs. I. was not available (being abroad), so a group O R_h donor was used (in case the mother was immunized to either the R_h or the R_h antigen). On Dec. 11, 1945, 50 ml. of the donor's blood was taken into 350 ml. of sodium citrate solution and at once transfused into the mother. Preliminary cross-matching tests showed that the donor's cells were compatible with the recipient's serum. Transfusion was given slowly over one hour because the recipient soon became restless and alarmed and experienced tingling sensations, throbbing in the head, nausea, vomiting, and pain in the lumbar

region. The reaction was fairly severe, and included rigor and rise of temperature from normal to 102° F. (38.95° C.). Samples of the recipient's serum collected one hour and four hours after the transfusion were markedly icteric compared with the pre-transfusion serum sample. A catheter sample of urine taken before transfusion was water-clear, but a similar sample taken one hour after transfusion was orange-amber in colour; no urinary casts were found.

FIG 2.—Second family. Third child (Pt.). Area of liver and spleen mapped out.

On the ninth day after the biological test strong Rh agglutinins of titre 1/64 (anti-D) were found in the recipient's serum. Finally, in January, 1946, the Coombs anti-human-globulin test was carried out on a pre-transfusion sample of the recipient's serum, and a positive reaction was obtained.

Case Report: Third Family

Mrs. L., aged 42, had never had a blood transfusion. She has a cleft palate, and has had the following pregnancies:—First: 1930, female, one month premature; moderately jaundiced for two weeks and died of pneumonia aged 16 months. Second: 1932; abortion at seventh week. Third: 1933, twins; one was of undetermined sex and died soon after birth; the other, a female, had convulsions and died, intensely jaundiced, on the eighth day. Fourth: 1935, male (M.I.); two weeks premature; never jaundiced; surviving and normal. Fifth: 1938, female (J.I.); became moderately jaundiced a day or two after birth, and jaundice persisted three months. Enlargement of liver detected when the child was a month old.

The fifth child (J.I.) has been under observation intermittently since infancy for hepatomegaly and splenomegaly. In December, 1945, her abdomen was very protuberant. The spleen was much enlarged and extended 3 in. (7.6 cm.) medially from beneath the left costal margin. The lower border of the liver was palpable two fingerbreadths below the right costal margin. In recent months epistaxes have occurred. A blood examination revealed slight secondary anaemia and a leucopenia. The child was intelligent and of about normal size. The mother's Wassermann reaction is negative. The clinical diagnosis was considered to be Banti's disease or splenic anaemia.

Rh Factor Investigations.—Mother, A, Rh+ (R,R⁺), and no irregular antibodies detected in her serum. Husband, O Rh+ (R,r). M.I. (fourth child), A, Rh+ (R⁺r). J.I. (fifth child), A, Rh+ (R,R⁺). Wiener's conglutination test was negative. The Coombs anti-human-globulin test, using the red cells of the children, was negative. The biological test, using the husband as donor, gave a negative reaction. Subsequent to the biological test no irregular agglutinins appeared in the mother's serum. There was therefore no evidence of iso-immunization of the mother to an antigen in the red cells of her foetuses.

Discussion

In some infants affected with congenital haemolytic disease, when Rh agglutinins or an incomplete antibody has been demonstrated in the maternal serum, we have observed liver or

splenic enlargement, or both, in addition to jaundice. Occasionally such enlargement of liver or spleen persisted for several weeks after jaundice had disappeared. Other investigators—for instance, Wiener and Wexler (1943), Wiener (1944), Wiener, Wexler, and Gamrin (1944), and Langley and Stratton (1944)—have also observed jaundice, hepatomegaly, and splenomegaly in newborn infants affected with haemolytic disease. The relationship between neonatal jaundice and liver damage and the Rh factor has recently been dealt with by Skelton and Tovey (1945).

There are not, apparently, any reports on Rh factor investigations in families in which there were older children or adolescents with liver or splenic enlargement. Since previous rhesus-immunization of the mothers was clearly proved in the first and second families in this report, it is possible that the hepatomegaly and splenomegaly in these children is a late manifestation of damage caused by the noxious action of Rh iso-antibodies. In this connexion it is to be noted that Rh group-specific substances have been demonstrated in the liver, spleen, kidney, etc., by Boorman and Dodd (1943). Cappell (1944) states: "The severity of foetal liver damage in some cases of haemolytic disease is an indication that harmful effects are by no means confined to the blood and haemopoietic organs."

If damage by Rh iso-antibodies was the cause of the liver and splenic enlargement in the affected children of the first and second families, it then becomes intriguing to know why, in the first family, the second, fourth, and seventh children, who were all Rh-positive, were not affected with jaundice, hepatomegaly, or splenomegaly, whereas the sixth infant died jaundiced and the eighth had a moderate degree of jaundice but recovered spontaneously. The Rh-negative child in family No. 1 has always been normal. That the first child in family No. 2 was not affected, although Rh-positive, is understandable, for it is well known that in haemolytic disease the firstborn is frequently unaffected. However, since rhesus-immunization of the mothers was proved in the first two families, it seems likely that congenital haemolytic disease was the cause of the liver and splenic enlargement. The cases of the children affected with splenomegaly and hepatomegaly in the first two families are unusual in that jaundice apparently never occurred. It is, however, well known that some infants affected with congenital haemolytic disease may be profoundly anaemic though never jaundiced. On the other hand, in the third family the affected child was jaundiced for several weeks, but the possibility of rhesus-immunization of the mother was definitely excluded.

Familial cirrhosis of the liver has long been recognized clinically, and our findings in the first family suggest that in such cases Rh factor investigations are essential in a search for the true cause. It would also seem, from our findings in the second and third families, that Rh factor investigations should be applied in cases diagnosed clinically as Banti's disease or splenic anaemia in children. Liver and splenic enlargement in children may, apparently, in some cases be attributable to congenital haemolytic disease, and, if this is so, Rh factor investigations are essential in the differential diagnosis of unexplained forms of hepatomegaly and splenomegaly occurring in children or adolescents.

We wish to thank Dr. T. R. Davies, Dr. G. S. Lewis, and Dr. F. Pearson for their co-operation in securing the investigation of the families reported in this paper. We desire also to thank Dr. R. R. Race of the M.R.C. Serum Unit, Cambridge, for carrying out Rh genotyping and the Coombs test in the third family, and for supplying rabbit sera for the Coombs test in the first two families.

TUBERCULOSIS IN SERVICE MEN: PRELIMINARY REPORT

BY

H. C. MUKERJI, M.Sc., M.R.C.S.

Senior Medical Officer, Preston Hall, Maidstone

So much has been said on the subject of tuberculosis that it is almost impossible to write anything new, except about the specific drug that remains to be discovered. But while I was analysing the Service cases of this war, nearly 3,000 of which have passed through the tuberculosis section of this hospital, I felt that there was ample room for rearrangement of emphasis on different factors of this disease within the framework of what is already known.

Tuberculosis is still one of the major causes of death and disablement among young people in this country, but it is doubtful if in any other disease so many avoidable and grievous mistakes are made. It would be futile to blame the M.O.s and general practitioners for these lapses. The teaching of this disease in most of our general and teaching hospitals is very inadequate. It is astonishing that a state of affairs should be allowed to exist in which tuberculosis services are almost completely dissociated from the general hospitals. After all, it is through these general hospitals that most of our young doctors pass into practice. Osler's fear that tuberculosis will become an overspecialized subject has come true. It is important to realize that specialists, with all their knowledge, are powerless to help the patients unless the M.O.s and general practitioners can recognize the disease in time, and refer the cases to them.

I hope to publish a full and detailed analysis of these cases in the near future, but here I will try to give, as a preliminary report, only the broad conclusions which have emerged from the analysis.

More Important Groups of Presenting Symptoms

1. *No Symptoms*.—The person feels quite fit and does his normal Service duties without any apparent ill effect. Routine or incidental x-ray examination reveals pulmonary tuberculosis. It is worth noting that cases with fairly extensive disease may be found in this group.

2. *Vague Symptoms*.—A large number of patients belong to this group. Feeling "out of sorts," general malaise and lassitude, lack of concentration and interest in their jobs, etc., are the common symptoms. These may be persistent or periodic.

3. *More Definite Symptoms*.—Cough with or without sputum, loss of weight, night sweats, pleuritic pain, and dyspnoea are some of the common symptoms in this group.

4. *Haemoptysis*.

5. *Gastric Symptoms*.—Symptoms simulate gastritis and/or peptic ulcer. Pulmonary tuberculosis is diagnosed when preliminary screening of chest is done before a barium meal test.

6. *Influenzal Symptoms*.—In a certain number of cases the presenting symptoms may be indistinguishable from those of influenza and very often they are diagnosed as such. At a future date, when tuberculosis is recognized, it is said that the attack of influenza "flared up" a latent lesion. It is more true to say that influenza was wrongly diagnosed and that those symptoms were the expression of the tuberculous pathological process itself. It may be further said that it is unusual for true attacks of influenza in a tuberculous person to flare up the disease if the proper precautions are taken.

Diagnosis

For the purpose of diagnosis, reliance on physical signs may be so misleading as to be almost dangerous. It is surprising that a large number of these Service patients, who reported sick with definite symptoms such as persistent cough, expectoration, loss of weight, general lassitude, and in some cases even haemoptysis, were given "medicine and duty" because physical examination of the chest was negative. Despite persistent symptoms, skiagrams were not advised for the same reason—viz., absence of physical signs. The effect of such an attitude on the early diagnosis of tuberculosis is obvious. Here again it will be wrong to blame the M.O.s. For generations the importance of physical signs in chest diseases has been drummed into us, and it has been copied from edition to edition of textbooks.

To-day, when x-ray films have shown the inadequacy of physical signs over and over again, we are loath to accord to physical examination second place, as if to do so would be to renounce the supremacy of man over machine.

The physical sign in its proper perspective is of great value, but careful analysis and evaluation of a good history should be the basis of every diagnosis. If history and symptomatology, however remotely, suggest tuberculosis the case must be x-rayed. It should not be loosely labelled as "idiopathic," "functional," "bronchitis," "influenza," etc., without proper investigation. In a doubtful case it is better to err on the side of "too many" rather than "too few" skiagrams.

Treatment

1. Rest is still the most important measure in the treatment of tuberculosis.

2. Collapse therapy is only ancillary and never a substitute for rest. I know of a few instances in which the patient was allowed to go home on the same day as, or within two to three weeks of, induction of an artificial pneumothorax. This practice is fraught with danger and has little to recommend it.

3. In the acute exudative type of lesion a preliminary period of bed rest should precede any attempt at artificial pneumothorax. In suitable cases phrenic crush and/or artificial pneumoperitoneum may with advantage be considered during this period of rest.

4. When radiologically the lesion is close to the hilum it is advisable to carry out bronchoscopy before inducing an artificial pneumothorax. In this type of case a main bronchus is very often involved, in which event artificial pneumothorax is contraindicated.

5. In certain cases it is justifiable to continue an artificial pneumothorax for a limited period of time even when the artificial pneumothorax is unsatisfactory in the commonly accepted sense of the word. Needless to say, these cases need very careful handling, and should be done only by those "who know what they are doing."

6. Abandonment of artificial pneumothorax should always be gradual.

7. Artificial pneumoperitoneum has a greater scope than is accorded to it to-day.

It is interesting to note that collapse of the lung, varying from small areas to whole lobes, occurs far more frequently in tuberculosis, especially in association with artificial pneumothorax, than is generally realized. There appears to be a high correlation between collapse and fluid formation in the case of artificial pneumothorax.

The Age Factor in Assessment

The importance of age in assessing a case of tuberculosis is very often overlooked. It is not fully appreciated that a radiological lesion in a person 20 years old has a very different significance from a similar one in a person of 40. In a patient under the age of 25-27 years a tuberculous lesion, however innocuous it may appear on clinical and radiological examination, should never be declared inactive unless the patient has been under close observation for a fairly long time, during which period his exercise tolerance has been satisfactory. Even then it is desirable for him to have a radiological examination from time to time.

Rehabilitation

There is no other disease for which the statement "you treat the person and not the disease" is more true. Hence for proper management of a tuberculous case not only do you need the full clinical data, but due note must be accorded to the sociological and temperamental aspects of the patient. The importance of rehabilitation in the treatment of tuberculosis cannot be overestimated. During this period the patient is gradually hardened off through occupational therapy and sheltered employment under medical supervision. Moreover, in the present state of our knowledge, by this method alone it is possible to judge what sort of life he will be able to lead outside. Furthermore, the patients themselves learn what they can and what they cannot do.

Strict exercises—viz., measured walks, etc.—are of great value in the beginning, but these are too artificial when compared

with the ordinary routine of life. Whenever possible they should be followed up by observing the patient while he works and lives under conditions approximating to those prevailing outside the sanatorium.

Conclusion

If the history, however remotely, suggests tuberculosis the patient must be x-rayed.

If the patient is below the age of 25-27 no lesion should be declared inactive unless he has been under observation for a period of time. During this period his clinical examination, skiagrams, and exercise tolerance should be satisfactory.

There must be close co-ordination between general hospitals and tuberculosis services.

My thanks are due to Dr. F. R. G. Heaf, Hon. Medical Director, for his help and kind permission to analyse these cases.

Medical Memoranda

Amoeboma of the Hepatic Flexure

The following case illustrates the importance of keeping amoebiasis in mind in the Tropics and of carrying out a sigmoidoscopy even when stools are entirely negative.

CASE RECORD

A well-nourished Gurkha sepoy aged 23 was admitted to hospital on Dec. 14, 1945, having complained of pain in the right chest and hypochondrium with an evening pyrexia for three weeks. There was no history of previous ill-health, the patient being questioned particularly regarding bowel disorders.

On examination a few rhonchi were found at the right base, and in the right hypochondrium a rounded swelling, $3\frac{1}{2}$ in. (8.9 cm.) in diameter; it was rather hard, not fluctuant, not hot, slightly resonant, and tender but not exceedingly so. It appeared not to be continuous with the liver, and to be attached to the rectus abdominis. The stools contained no blood or mucus on naked-eye inspection, and were repeatedly negative for exudate, cysts, and ova. The white cells numbered 14,000 per c.mm., of which 80% were polymorphs. The urine was normal. By Dec. 18 the swelling was becoming more definitely adherent to the abdominal wall, and indeed appeared to be an abscess within the wall about to involve the skin. Sigmoidoscopy showed many patches of ulceration typical of amoebic infection; unfortunately no scraping was taken.

The radiological report on the 19th was as follows: "*Straight skiagrams in upright and right decubitus positions*:—Multiple fluid levels in the small and large intestines proximal to hepatic flexure. *Barium enema*:—Screening; passage of enema normal up to proximal end of transverse colon, which became distended as the enema proceeded. The patient had a desire to return the enema, and some escaped around the nozzle. After a delay of several seconds a narrowed stream of barium passed onwards into the ascending colon and caecum. The appearances suggested a constriction $2\frac{1}{2}$ in. (6.3 cm.) long and about $1\frac{1}{6}$ in. (0.4 cm.) in width. The site of constriction corresponded with the site of the tumour and of tenderness. *First skiagram after enema*:—Gut filled from caecum to rectum; haustrations normal; hepatic flexure ill-defined, proximal end of transverse colon showing an abrupt ending. *Skiagram after evacuation*:—No change in amount or density of barium shadow in caecum and ascending colon; rest of large intestine partly emptied. *Skiagram of lateral view in supine position*:—No barium shadow extending anteriorly into region of tumour. *Conclusion*: Appearances suggestive of chronic obstruction at or near hepatic flexure."

A diagnosis of amoeboma involving the tissues of the anterior abdominal wall was made, and on Dec. 19 emetine (1 gr.—65 mg.—daily \times 6) and penicillin (100,000 units daily \times 8) were started. A dramatic reduction in size and tenderness of the swelling resulted: on the 9th day of treatment it was only the size of a hazel nut, and was hard and free from tenderness. The total white cells had fallen to 11,400 per c.mm. After three days' rest a further 4 gr. (0.25 g.) of emetine was given, together with a course of chiniofon retention enemas. The patient was afebrile throughout his stay in hospital except for a rise to 100° F. (37.8° C.) on Dec. 18.

On Jan. 14, 1946, the radiologist reported: "*Barium enema*:—Filling of whole of large intestine now normal. No evidence of any intestinal lesion or spasm." Sigmoidoscopy on Feb. 2 showed a normal mucosa except for a very few minute flat-topped "warts" characteristic of healing pin-point craters. Nothing abnormal could be palpated in the abdomen.

In this case the criteria of amoebic stenosis as distinct from carcinomatous stenosis were fairly well fulfilled, the narrowing being of considerable length and width.

I desire to express my thanks to Lieut.-Col. H. R. S. Hartley, I.A.M.C., surgical specialist, and to Lieut.-Col. R. Heathcote, I.A.M.C., radiologist, for their great interest in this case; and to Lieut.-Col. H. M. Salamat Ullah, I.A.M.C., for permission to publish this report.

C. F. J. CROPPER, M.R.C.P.,
Lieut.-Col., I.A.M.C.

Reviews

CLINICAL NEUROLOGY

Introduction to Clinical Neurology. By Gordon Holmes, M.D., F.R.S. (Pp. 183; illustrated. 12s. 6d., plus 6d. postage.) Edinburgh: E. and S. Livingstone. 1946.

The contributions to the literature of their subject which we owe to great clinicians fall easily into two categories. There are those papers and communications in which they place on record their original contributions to knowledge, and there are the textbooks and monographs in which they present to the general body of their professional brethren the sum of their experience, in a part or over the whole of their own field, and thus take their due place as teachers. Gowers, one of the master builders of modern clinical neurology, wrote numerous monographs and one great textbook, in them displaying the intimate familiarity with his material which is the foundation of that clinical wisdom in which he was so pre-eminent. Of original papers in the strict sense his sum was relatively small. Dr. Gordon Holmes, a one-time pupil and now a worthy successor of Gowers, can claim a long and distinguished bibliography of original contributions to neuropathology and clinical neurology, but hitherto he has not summed up his experience in a book or monograph for the benefit of those who have not had the privilege of following his teaching by the bedside and in the out-patient clinic. There can be few neurologists of the present time who have not listened to this teaching in the wards at Queen Square, but to those who have as well as to those who have not, this "Introduction" will be welcome.

Often believed to be the most complex field of medicine, assuredly one in which the British school of medicine has been pre-eminent, neurology is certainly one calling for logical and sustained thinking and, at least in its higher reaches, for a sound basis of anatomy and physiology. It is thus an excellent training discipline for anyone who wishes to graduate into medical science with a view to teaching and research, or even to teaching alone, in any branch of medicine. Therefore this "Introduction" should prove of value to a wide circle of readers, for it is in fact an introduction to the clinical method in its most rigorous aspect. It is not a textbook of clinical neurology and does not deal with diseases, but discusses and analyses the symptoms and abnormal signs that may be presented by any case of nervous disorder on clinical examination. It is, in fact, an exposition of first principles in clinical neurology.

The plan of the book is one familiar to all who have studied at Queen Square. The "systems"—motor, sensory, and reflex—vision and the ocular movements, the speech function and its disorders, and visceral neurology are all dealt with in turn. Each section—e.g., that on the motor system—contains a brief statement of the relevant anatomical and physiological factors, and chapters on methods of examination and on the various categories of disordered function that the clinician recognizes under the heading of "signs and symptoms." Here, lucidly presented, and displaying that balance of emphasis that comes from an intimate knowledge of the methods and needs of clinical study, are those foundations of clinical neurology upon which alone the student of the subject can hope to build with the aid of experience a sound edifice of theoretical and practical knowledge, of clinical wisdom.

This little book will recall to those who have been Dr. Gordon Holmes's clinical assistants and clerks at Queen Square those strenuous and stimulating ward rounds that have helped to mould so many of the leading neurologists of to-day in all countries, and from them as from a younger generation of readers this "Introduction" will be sure of the warm welcome it deserves, for indeed no physician living has contributed more to the international prestige of British medicine at this time than its author.

MODERN PSYCHIATRY

Modern Psychiatry. By William S. Sadler, M.D. (Pp. 896. 50s.) London: Henry Kimpton.

In this large volume the author has attempted to construct a reference book of what he calls "personology," in which the practitioner may find information about the diagnosis and treatment of disturbances of the patient as a whole. Psychosomatic

medicine is dealt with briefly in the very forefront of the book, in an introduction, in order to stress the need for satisfying the patient who, having been to hospital, may, with great justification, say, "If this is the place where you come to find out what is not the matter with you, where do I go to find out what is the matter with me, for I am a most miserable and unhappy woman?"

The first part of the book is concerned with the meaning, structure, and maladjustments of personality at all ages. Next the psychoneuroses are taken up in considerable detail, reference being made to people who are merely difficult and queer as well as to those presenting frank manifestations of accepted psychoneurotic diseases. Thirdly the psychoses are similarly dealt with, and also mental defect. The chapter on this is termed "defective reaction types," among which are classed not only mental deficiencies but epileptics and endocrine deficiency cases as well. In the final part all forms of treatment are considered, including physical methods. This section has an interesting chapter on the influence of philosophy and religion. A brief description of the various schools of psychiatry is given in an appendix. Among these the author includes an "American School" which is evolving out of the others. The book is rounded off with an adequate bibliography and a full index.

This volume is too bulky to be recommended for general reading, but as a reference book it should be invaluable. The practitioner will find it difficult not to get from the ripe experience of the author some useful and stimulating information on any subject connected with the mind in health or disease.

MEDICAL PROGRESS IN THE ALLIED COUNTRIES

Acquisitions Médicales récentes dans les Pays Alliés. By A. Abaza. (Pp. 706, 1,000 francs.) Paris: G. Doin et Cie, 8, Place de l'Odéon. 1946.

Dr. Alphonse Abaza, a member of the medical staff of U.N.R.R.A., has attempted in this book nothing less than a general account of medical progress, mainly in Great Britain and the U.S.A., during the enemy occupation of France. In performing this colossal task his industry must have been prodigious, and the result is a comprehensive series of monographs which should be of great service to those who have been cut off from contact with the rest of the world, and find it difficult to grasp what has been happening there. Penicillin and other antibiotics and new forms of sulphonamide treatment occupy nearly half the book; the choice of subjects for the rest is an interesting reminder to anyone of the advances of the past five years. They include epidemic hepatitis, atypical pneumonia, D.D.T., B.C.G., methods of immunization against diphtheria, pertussis, typhus, and enteric fever, air sterilization, oestrogens, alloxan diabetes, new forms of insulin, dicumarol, fluorescence microscopy, thiouracil, thymectomy, and ligation of the ductus arteriosus. Large lists of references are given, many of which, especially in an appendix, are quite recent. The medical profession in France will find this work invaluable, and others in more fortunate countries may find it a useful source of information.

SURGERY OF THE OESOPHAGUS

Injuries and Diseases of the Oesophagus. By G. Grey Turner. Being the George Haliburton Hume Memorial Lectures. (Pp. 100; illustrated. 15s.) London: Cassell and Co.

Prof. Grey Turner in 1943 paid tribute to the memory of his former teacher and chief in the George Haliburton Hume Memorial Lectures delivered at Newcastle-upon-Tyne. These lectures on injuries and diseases of the oesophagus have now been republished in book form and are thus made available to a larger circle of readers. Prof. Grey Turner relates that his interest in the surgery of the oesophagus was first aroused by a clinical lecture on cancer of the gullet delivered by Hume to his pupils and by cases under his care. That interest has never flagged and, although an extensive acquaintance with the relevant literature is displayed, it has provided the author with a vast personal experience, upon which he has drawn in order to present a clinical picture from the point of view of a general surgeon. In consequence he has something, but not very much, to say about endoscopic methods of examination and treatment, but rather he describes those conditions which demand something more than endoscopy and lie in the territory

where the throat specialist and the general surgeon must co-operate. The second chapter, on examination and diagnosis, is an example of this, for it is shown how much can be learnt from a proper clinical examination apart from the use of the oesophagoscope, which of course is not ignored. How deeply Prof. Grey Turner has pondered over the difficulties of the surgery of this elusive and rather defenceless tube is shown in the third chapter, on congenital anomalies; and while allowing himself the liberty of indulging in some reasoned speculation he gives a fascinating account of what has been attempted for the relief of infants so afflicted and foretells the lines along which further progress is possible.

The oesophagus still presents more than an average share of unsolved, or at any rate partially solved, problems, and among these the management of achalasia and of malignant disease are prominent. The views of the author on these debatable matters must command the respect due to one who has had great experience and some remarkable success, due largely to careful preliminary investigation and independence of thought. He is sceptical, like some others, about the short oesophagus, and there are other points which he has not attempted to discuss fully. His readers and many admirers of his work will be none the less grateful for what he has to say, and will be fascinated by the graphic description of his clinical experiences, and the accounts of some of his disappointments and impressive successes, so faithfully related.

Notes on Books

The March of Medicine in Western Ontario, by Dr. EDWIN SEABORN (Toronto: The Ryerson Press; London: Hatchards, Ltd., 30s.) falls naturally into three phases: the Indian period, the French, and the British. The first period chiefly, though not entirely, is a record of witchcraft and folklore; the second is concerned with medicine from the days when French explorers first set foot in Canada and found strange herbs as curative agencies. The French brought to Canada the first physician from Europe, François Guitault. The main bulk of the book, however, deals with the steady progress of British medicine in Western Ontario from humble beginnings to its present state of high efficiency. Dr. Seaborn has searched available records and for the later phases has drawn upon personal recollections and correspondence, bringing to life in an interesting manner the pioneers in a medical world who came from Britain and from the United States. His position is such that he can speak with authority, and he has brought to his task great enthusiasm and industry. The result is a work invaluable as a reference for the medical historian. The book is copiously illustrated and well documented.

A twelfth edition, revised and enlarged, of the *NAPT Handbook of Tuberculosis Activities* has been published, with a Commonwealth and Empire supplement, by the National Association for the Prevention of Tuberculosis, Tavistock House North, Tavistock Square, London, W.C.1. It is a complete directory of tuberculosis dispensaries, clinics, sanatoria, etc. The main contents are grouped under local authority tuberculosis schemes, mass radiography units, centres for thoracic surgery, sanatoria and hospitals for the treatment of tuberculosis. The editor, Dr. Harley Williams, in his foreword notes that the years since the publication of the last regular edition have seen many changes, but the British system of tuberculosis control has survived them, and remains substantially unaltered. Since the first edition appeared some thirty years ago enormous progress has been made, but the NAPT is still conscious of what remains to be done both at home and over-seas. The price of this very useful handbook is 7s. 6d.

Outline of Industrial Welfare and Personnel Management is published by the Industrial Welfare Society, 14, Hobart Place, London, S.W.1, at 1s. post free. This booklet has been produced as a convenient introduction to the functions of a personnel department. It is written to help those who may wish to have a summary of the scope and content of personnel work. A full list of sources of reference is included as an appendix, together with a list of voluntary organizations and Government departments concerned with different aspects of social and industrial welfare activities.

The 102nd edition of the *Medical Directory*, for the year 1946, has been published by Messrs. J. and A. Churchill Ltd. The number of entries in the main section is 70,461, not counting the names of 4,070 temporarily registered practitioners which appear without addresses near the end of the book. The total 70,461 is larger by 1,458 than the figure for 1945 and nearly twice as large as that for 1900.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JUNE 29 1946

REHABILITATION

The treatment of a patient is not completed until that patient is back at work and able to support himself. This is obvious enough, but it is an idea which has been widely realized only during the last five years, and perhaps even at the present day it is not generally accepted by the medical profession. The Council of the British Medical Association in 1945 took the initiative and set up a committee to consider and report on rehabilitation as it was practised and to make recommendations for the future. Its report appears in our *Supplement* this week, and the subject is considered from two aspects: first, the facilities that exist at the present time are described and reviewed, and then planned rehabilitation is discussed. Of disabled persons, 25% are surgical, mostly accident or orthopaedic, 25% are neurotic, and 50% are medical patients. Surgical rehabilitation is not as a rule difficult, because common sense indicates, to a large extent, what a man without a leg or an arm can and cannot do; and, further, the disease is normally not progressive. It is easy, therefore, to explain the facts to the management, and once the problem is settled it usually does not require further attention. The limitations of the neurotic, the tuberculous, or the patient with heart disease are much more difficult to assess and explain. Most attempts at rehabilitation therefore have up to now been made by orthopaedic surgeons, and this is well shown in the first part of the report, dealing with present facilities, but other branches of medicine must follow their lead even though the path will be more difficult.

The first recommendation is that the medical services of industry should be part of a comprehensive health service, administered by a single Government Department under a Minister responsible to Parliament. This is fundamental, and until it happens no rehabilitation scheme will work smoothly; when it happens the physician and social service in hospital will be able to work with the industrial medical officer and welfare officer in industry, as occurs at present with the large firms who have established such services with great success. Unfortunately for rehabilitation, though fortunately for the nation, the bulk of industry is carried on by small firms, and the only way for these to achieve the desired results is for groups to combine in local areas and employ doctors and welfare officers. Doubtless in this way there will be a variety of employment within the group, so that jobs may be found for people with all types of disablement. At the present time, however, between the individual health service and the industrial health service comes a third party—the Ministry of Labour—whose inten-

tions are good, but since it cannot possibly have an understanding of the problems it serves only to obstruct the project and prevent the two services getting together. A great example of this lack of understanding was the plan, reasonable to the lay mind but extremely foolish to anyone with a knowledge of medicine, of rehabilitating silicotic coal-miners in South Wales as electric arc welders. In its attempt to achieve satisfactory employment for the disabled the Ministry of Labour has decreed that a register shall be kept, and that the labour of firms who do not have 2% of their employees on this register shall be controlled; that is a typical Civil Service approach to the problem, but what is wanted is that work within their capabilities shall be found for the grossly disabled. The former approach does not even achieve its object, since it merely means that the 2% will be made up of those with flat feet and subject to bronchitis, while nothing is done for those grossly incapacitated. Let it be stressed again that success can be achieved only by doctors in hospital with social service staff working together as a team with industrial medical officers and their welfare officers.

Another thorny aspect of the problem is the question of who directs the intermediate part of the treatment—exercises, gymnastics, and occupational therapy. In most hospitals in Great Britain there has been developed a department of physical medicine, a department which seems to cover a group of unrelated subjects—a study of rheumatic diseases, treatment by radiation, and medical gymnastics. This is undoubtedly a bad division of medicine, but it is so firmly established that it would be difficult to undo; further, it is impossible for each physician and surgeon in a hospital to have his own gymnastic and occupational therapy department, so that it seems inevitable that these should be under the general direction of one member of the staff, even if there is no clear reason why that member should be the physician who is a specialist in rheumatic diseases. The orthopaedic surgeons would undoubtedly like to control these departments, but common sense seems to suggest that they will be very much better under the care of a physician. Manifestly, this physician must work in the closest touch with the physician or surgeon under whose care the patient was for his initial complaint, and later they must together co-operate with the industrial medical officer. The report insists on the need for continuity of care and the overall responsibility by the specialist in charge, and supervision at all stages by a qualified medical practitioner responsible to him.

Many groups of people are disabled during childhood as a result of congenital abnormalities or of diseases such as rheumatic fever or poliomyelitis. It is important that these individuals are trained for suitable jobs in life and that they should be properly placed. At the present time the situation for them is most unsatisfactory. Theoretically and on paper the facilities for training them are there; they come under another Government Department—the Ministry of Education—but in practice the achievement of them is difficult, particularly in country areas. This,

however, draws attention to the fact that the placement of the disabled is only a part of a much bigger problem—the satisfactory placement of all individuals. Much harm, not only physical but usually psychological, is done by bad placement. Perhaps industrial medicine will be judged more on its success or failure in placing individuals in industry than on any other aspect of its work.

THE FATALITY RATE OF MEASLES

Measles is a familiar but important problem in child health. Despite the success which has been achieved in lowering the mortality from this disease it remains one of the largest causes of death among children. That the clearly defined characteristics of the trend of the mortality from measles—the seasonal rise, the definite periodicity, the marked progression with urbanization, the sensitiveness to social and environmental conditions—have had a fascination for the epidemiologists and workers in public health is clearly evident from the large number of articles on these subjects. The relation between degrees of urbanization and measles mortality can be easily demonstrated from the statistics of the inter-war period: during 1921–38 the mortality per 100,000 living was 140 in the county boroughs, 79 in the urban districts, and only 41 in the rural districts. The association between social conditions and measles mortality was equally striking: the mortality at ages 1–2 in 1930–2 by social class of father was 25, 70, 194, 246, 469 for social classes I to V. The apparent simplicity of the epidemic curve of measles has given rise to many hypotheses concerning the spread of infection. These give a fair description of an outbreak, but since most were of necessity based on mortality, as the incidence was unknown, they could not be rigidly tested. The chief difficulty in obtaining a simple mathematical expression for the trend of measles is that of spatial distribution. The spread of infection through a city from the one or more foci in which it begins is comparatively slow and variable, and the disease may take several months to cover the whole area. If as sometimes happens the first appearance of the outbreak is postponed, then the disease dies down as usual in the summer months, leaving districts unattacked, and as a consequence the number of susceptibles is unduly high in the next outbreak.

Extensive data on the incidence of measles have been scarce and most of the work in England has been confined to deaths, since measles was not generally notifiable before 1940, although in some areas notification or a modified form of notification—e.g., the first case in a household—had been made for varying periods. During the first two years of notification, 1940 and 1941, over 800,000 cases were notified. The death rates for these years were 21 and 29 per million and were less than one-twelfth of the rates of 30 years earlier. Some cases of measles escape notification because medical aid is not sought, measles being regarded by the parents as a mild disease. If allowance is made for these cases it is evident that the fall in mortality was not due to any decrease in prevalence. The surprisingly large reduction that must have taken place in the

case fatality led Lieut.-Col. William Butler¹ to review the recent trend of measles. For the first time it was possible to compare the trend of mortality with that of incidence for London and the large towns. It is well known that for many infectious diseases the fatality rate varies not only between epidemics but during an epidemic. Col. Butler has attempted to relate the deaths to the appropriate cases from which they were derived by means of a smoothed moving average which he termed the "batch fatality rate." The calculation of this rate was based on a nine-weeks period, and is found by dividing the deaths during the last five weeks by half the cases in the first four weeks plus all the cases in the middle (5th) week plus half the cases in the last four weeks. Though all the assumptions on which this index is based may not be justified the batch fatality rate does give a good approximation to the trend of fatality.

Col. Butler has in the April and May issues of the *Monthly Bulletin* of the Ministry of Health and the Emergency Public Health Laboratory Service extended the application of his index up to early 1946. The batch fatality rate during the six years 1940–5 showed a winter maximum and a summer minimum. The maximum ranged from 4.2 to 6.4 and occurred once in October, twice in November, once in January, and twice in February. The minimum value varied from 0.2 to 1.4 and appeared once in July, three times in August, and twice in September. An interesting feature of the maximum values is that they do not occur in the winters which contain the peaks of the epidemics—e.g., the peak of notifications in the 1940–1 epidemic occurred ten months after the maximum batch fatality rate of 1940 and eleven months before the maximum batch fatality rate of 1941. This may be partly due to the fact that notifications tend to be more complete in periods when the disease is very prevalent than when the incidence is low and slight attacks are more likely to pass unsuspected. The batch fatality rates for the first nine weeks of 1946 were exceptionally high, with a maximum of 7.6. The largest value for the preceding six years, 6.4, was exceeded three times, and on seven occasions higher values were found than the yearly maxima of 1941–4. That the case fatality during the first weeks of this year was large could have been shown by the customary method of relating the deaths in the period to the number of notifications. The usual approximation to the fatality rate gives, for the first nine weeks, a rate of 4.6 per 1,000 in the great towns, whereas for the corresponding period in the six preceding years the rate ranged from 1.3 to 4.1. If short periods are used the method of relating deaths and cases in the same time-interval will understate the actual case fatality when the incidence is increasing rapidly, and conversely it will overstate the actual rate when the incidence is falling rapidly, and a rapid change is a feature of measles—e.g., in 1945 the notifications ten weeks either side of the maximum differed from the maximum by about 15,000. Col. Butler's batch fatality rate overcomes to a certain extent the effect of rapid changes in the trend of notifications, though his index has the properties of a moving average which tends to smooth out the peaks in a curve by spreading any abrupt change over a period.

FOOD-BORNE OUTBREAK OF STREPTOCOCCAL SORE THROAT

Milk-borne streptococcal infections are common enough, and numerous epidemics have been recorded in practically every country in which close attention has been paid to milk hygiene, but well-documented accounts of streptococcal food-poisoning due to other vehicles are uncommon. In the outbreak of tonsillitis and pharyngitis recorded by a team of American Army workers¹ at Fort Bragg, North Carolina, infection appears to have resulted from the consumption of creamed eggs served for breakfast. The mode of preparation of the eggs could not be ascertained accurately, nor was the way in which they became contaminated at all clear; but the eggs had been boiled, sliced by hand, and left, presumably at kitchen temperature, for ten hours before being served. Of 228 men who ate in the same messroom, 86 (37.7%) were attacked within three days, most of them within two days. There were 18 (14.7%) secondary cases among those who had escaped primary infection. Accompanying the 86 primary cases were 9 symptomless carriers, and 22 symptomless carriers accompanied the 18 secondary cases. Clinically the cases were exactly like those met with in air-borne infections. Patients whose tonsils had been removed had less exudate in the throat, harboured smaller numbers of streptococci, and rid themselves of the infecting organisms more rapidly than those whose tonsils were still intact. For example, only 19% of the tonsillectomized group were still carrying streptococci after six weeks as opposed to 57% of patients with tonsils.

The effect of sulphadiazine, in ordinary dosage, was studied under controlled conditions on 110 patients admitted to hospital. Apart from alleviating the subjective symptom of sore throat, the drug had apparently little effect. No significant change was noticeable in the objective signs, nor was the incidence of non-suppurative complications any less in the treated group. The number of streptococci in the throat diminished during the period of treatment, but returned to "normal" as soon as the drug was stopped. Non-suppurative complications affected 13 patients—3 had acute rheumatic fever, 2 suspected rheumatic fever, 4 febrile relapses without localizing signs, and 4 an afebrile cardiac disturbance associated with electrocardiographic changes detected during convalescence. Once more, therefore, the association between haemolytic streptococcal infection and acute rheumatism is manifested.

For the diagnosis of streptococcal infection, the authors insist not only on the presence of haemolytic streptococci in a throat swab, but also on the demonstration of a rise in the serum content of streptococcal antibodies. Extensive experience of upper respiratory infections at Fort Bragg has shown that about half of all patients admitted to hospital with an exudate in the throat do not harbour haemolytic streptococci; and that many patients suffering from a sore throat from which haemolytic streptococci are isolated have no rise in streptococcal antibody titre and are merely fortuitous carriers suffering from some other form of respiratory disease. In the present outbreak 80% of all patients admitted to hospital showed a rise in the antistreptolysin content of the serum, and 20% in the antifibrinolysin content. Altogether 85% of patients had a rise in one or other, or both, antibody titres. It is of interest that although the infecting organism belonged to group A, type 5, none of the patients developed a rash. In many milk-borne outbreaks cases of scarlet fever and of septic sore throat have appeared side by side, but in spite of a normal proportion of Dick-positive subjects at risk in the exposed population at Fort Bragg no scarlet fever cases were observed.

HUMORAL TRANSMISSION OF NERVE IMPULSES

Dr. Otto Loewi has discussed in the Janeway Lectures,¹ given in New York, the present position of the theory of the humoral transmission of nerve impulses, which has been built upon the demonstration he first made in 1921. He showed that when the vagus nerve to the frog heart is stimulated, acetylcholine is liberated and is responsible for the cardiac arrest. The theory supposes that, in general, nerve impulses are transmitted to the end organ they supply, or to another nerve, by the mediation of a chemical substance and not by the passage of an electrical current. So far we know of only two substances which serve this function, acetylcholine and adrenaline.

Acetylcholine itself has had little application because of its instability. Belgian physicians use it, however, to terminate paroxysmal tachycardia; it is given by intravenous injection and the initial dose is as much as 10 mg. If this amount is ineffective the dose is doubled, and up to 160 mg. has been injected at once. Acetylcholine is destroyed in the body so rapidly that there is no record of a fatality, though these large amounts cause momentary cardiac arrest. More stable esters of choline, notably the carbaminoyl ester known as carbachol ("doryl" and "moryl" are the proprietary names), are used in atony of the bladder or intestine. Two fatalities are on record, one at Oxford² in 1942 and one at Croydon a few months ago (p. 1002), both of which were due to an overdose of the "moryl" preparation. The value of carbachol in treating urinary retention is widely accepted; its value in preventing or relieving paralytic ileus has not yet received the widespread investigation it deserves, though Marden and Williamson³ describe its use.

The effects of acetylcholine are prolonged by the administration of physostigmine and still more by prostigmine, and for this reason these substances antagonize the action of curare on skeletal muscle. The resemblance between the symptoms of myasthenia gravis and those of curare poisoning led Mary Walker⁴ to use physostigmine in myasthenia. The success attending this treatment led to a closer analysis of the pathology of the disease. Walker's evidence⁵ that the skeletal muscles of these patients release a curare-like substance into the blood has recently been confirmed by Wilson and Stoner.⁶ Harvey,⁷ on the other hand, believes that in myasthenia the nerve liberates less acetylcholine than usual, for when acetylcholine is injected intra-arterially the muscles are much more than normally sensitive to its action. Myasthenic muscles react like muscles which have been denervated. Intra-arterial injection of acetylcholine, or of prostigmine, furnishes a useful diagnostic test; in myasthenia it produces contraction, while in the normal subject it causes temporary paralysis.

Loewi now puts forward a new theory to explain the great increase—as much as one thousand-fold—in the sensitiveness of muscle to acetylcholine which follows denervation. He suggests that the hypersensitivity of the denervated cell represents its true sensitivity, but that the nerve-fibre normally controls and reduces this sensitivity. Loewi proposes this as a second function of nerve fibres, in addition to their primary function of conducting nerve impulses. If the theory suggests a new experimental approach to this problem, which was revealed by Auer and Meltzer as long ago as 1904, it will indeed be useful.

OTITIS IN THE NEWBORN

Infections in the newborn are one of the most important causes of neonatal mortality; they probably rank next on the list after intracranial birth trauma and prematurity. In a series of 499 infants dying in the first month of life Macgregor¹ found infection at necropsy in 36.5%, and in no less than 73.6% in those dying between the second and fourth weeks. Much of this is the result of cross-infection in the nurseries of maternity wards and hospitals. Epidemics are not uncommon, and outbreaks of pemphigus, diarrhoea, and pneumonia are still too frequent. The late Prof. McKim Marriott used to stress that any infant properly and adequately fed (especially if on the breast) and without constitutional disease must, if losing weight, be suffering from some infection. That this might be true even in the neonatal period has often been overlooked. In the newborn, acute infections may run a very rapid course and cause death in a matter of hours; in the absence of a necropsy death may be wrongly attributed to intracranial birth injury.

When infection has been suspected attention has been focused particularly on the nasopharynx, skin, kidney, and bowel, and the ears have not been specially investigated, partly because of the difficulty of routine inspection of the eardrums at this age. The importance of regular examination of the ears in older infants suffering from gastro-enteritis and unexplained fever is recognized and otitis is known to be a common cause of failure to thrive.

Two recent papers stress the importance of otitis in the newborn. The first, by Couper,² deals with the empirical use of penicillin in a small series of 20 infants who were going downhill: 8 were premature and 12 full term, and all of the latter had acute otitis. No myringotomies were performed and 11 of the 12 infants recovered. Clinical improvement followed promptly on penicillin treatment, but weight gain was sometimes delayed. The second paper, by Lévy-Solal, Lelong, Joseph, and Debain,³ deals with 11 newborn infants seen during a nine months' period at the St. Vincent de Paul Hospital in Paris. In this series penicillin was not used, but results similar to those obtained by Couper followed myringotomy in every case. All the infants were breast-fed. In 5, the infection occurred between the tenth and twelfth days, in 2 on the fifteenth day, and in 4 between the fifteenth and twenty-first days. Symptoms were somewhat indefinite, but when looked for a recognizable syndrome was observed—taking the breast less well, not gaining weight, slight pallor, occasional vomiting, and some alteration in the character of the stools. The temperature varied but was never high; indeed it was sometimes normal, and in one case subnormal. The clinical picture suggested otitis, and although the drums often showed little change, myringotomy resulted in prompt improvement and gain in weight. In some cases the diagnosis was made *a posteriori* by the fact that immediately after myringotomy the weight began to increase. Of the 11 infants reported, 7 were cured by a single paracentesis and the other 4 required two or three. The authors further contend that an unrecognized otitis originating in the first fifteen days of life may be the cause of subsequent marasmus. Certainly it is the experience of most paediatricians that in a high proportion of necropsies on infants dying of marasmus there is found an otitis or mastoiditis that had been overlooked during life. The question arises whether, as is suggested in this paper, every infant who goes off his feeds and ceases to gain weight on two consecutive days should have a myringotomy forthwith (unless

there is an evident cause for the upset) or whether chemotherapy should be instituted. Further experience may provide the right answer; in the meanwhile the authors have done a service in recording their experiences, and paediatricians and obstetricians alike should bear in mind the possibility of otitis as a clinical entity in the newborn.

SOCIAL MEDICINE AT OXFORD

The Institute of Social Medicine at Oxford—the first of its kind—describes in its brief annual report a number of investigations now in progress under its auspices. It must be borne in mind that the observations and researches of such a body are in connexion with groups and populations rather than with individuals, and that they require different methods and collaborations from those undertaken in clinical medicine. One of the investigations is a child health survey in Oxford, using eight welfare centres in the city. The purpose is to study and compare the health, development, and sickness experience of children in all social groups from the first weeks of life to the age of five. Another investigation is a statistical analysis of sickness absence at a great industrial works near Oxford, including correlations of the main causes of sickness with such factors as age, sex, trade, and season. It is hoped later to take particular causes of sickness absence, such as peptic ulcer and the chronic rheumatic diseases, for a more detailed inquiry. A third investigation is an extensive survey of school-children at ages 11–15, in several districts of England and Scotland, to determine the varying incidence of thyroid hyperplasia in relation to the iodine content of drinking-water. An x-ray department has been set up at the Institute and is carrying out skeletal studies of several hundreds of children, including Dutch children in this country, with a view to discovering evidences of nutritional deficiency and the incidence of other abnormalities and also information, at present lacking, on the range of variability within the "normal" of bony characters at different years in the period of growth. A "pilot survey" has also been made of 42 pairs of twins of school age, with a record of face, eye, and hair colour, radiographical resemblances, and heights and weights, and a much wider inquiry with an extended range of anatomical and physiological observations is contemplated. It is thought that while human genetic studies in their medical bearings have been largely based on family trees, much might be learned from a continuing follow-up study of the growth, health, and sickness of individuals of the same age and parentage and living under identical nutritional and environmental conditions. A statistical analysis of still-birth rates and neonatal death rates in the counties and county boroughs of England and Wales, in relation to such factors as urban and rural conditions, population density, and local employment of women, is another useful enterprise. If some "black spots" are revealed by such an analysis a specific local survey will be undertaken. In addition to all this, the Institute has undertaken at the Radcliffe Infirmary a course of instruction in social medicine for students in the clinical period and has also issued a number of publications. Prof. John A. Ryle, the director, and his staff have had a very promising first two years of work.

Viscount Addison, M.D., F.R.C.S., Secretary of State for Dominion Affairs and Leader of the House of Lords, was entertained to lunch on his 77th birthday (June 19) by the other Labour peers, when the Lord Chancellor handed him an inscribed silver cigarette box.

BRITISH LEGION RHEUMATOLOGY UNIT

The British Legion unit of rheumatology at the Three Counties Emergency Hospital, Arlesey, Beds, has begun work, and the first patients, all ex-Service men and women, have arrived. It is a one-year scheme for the intensive treatment of arthritis, rheumatism, and allied diseases, under the direction of Dr. C. B. Heald, who has written a note on what is available or will be possible at this special unit.

The doctors in charge of the patients will be men who have made, or are making, rheumatology their special interest and work. The majority of the nurses have volunteered to work for the British Legion, to help ex-Service personnel suffering from these diseases. The physiotherapists have all been chosen because they possess some advantage in training or experience that helps to fit them into the team. The hospital is in the country, surrounded by a home farm, thus ensuring the quiet and sense of peace so essential in all forms of arthritis. Any question of isolation and inaccessibility to London as a result of this situation has been met by the Joint Council of St. John and the British Red Cross Society providing an almost daily "ferry service" in order that contact with friends and relatives may be kept alive and active. Since the patients will all be resident in the hospital, but not necessarily confined to bed, daily treatment will be available.

The first period of each patient's stay will be concentrated on an accurate basic diagnosis and assessment of his or her condition. During this time one of the advantages the unit has secured becomes most actively operative. It is maintaining close liaison with the Royal Free Hospital, and all general medical and surgical departments are continuously available, with their expert visiting consultant staff from London. The special departments have also signified their desire to support this investigation; for example, the professor of pathology lives near the hospital, and the senior throat and ear, skin and nerve specialists visit weekly. This is the first time that any London teaching hospital has so clearly associated itself with a scheme of this size and scope in an intensive attack on arthritis and rheumatism. The British Legion has also secured as its consultant observer Lord Horder, chairman of the Empire Rheumatism Council.

A feature of the scheme will be the steady and progressive attack on the patient's condition in an atmosphere of "no hurry, no worry, and we shall see you back into the wage-earning ranks if possible." For this aspect of the work, a rehabilitation supervisor has been appointed. Here the New Zealand Division has been most helpful, and has seconded its chief physiotherapist, Capt. Guyton, a medical corps officer, with extensive experience at the hot springs of Rotorua and Hanmer. His duties will range from supervision of the diversional and recreational needs to the replacement of patients in industry. The Ministry of Health has also shown support and collaboration by approving the unit as suitable for the appointment of a specializing resident medical officer.

ROYAL MEDICAL BENEVOLENT FUND Projected Homes for the Aged

Sir Arnold Lawson, in his address from the chair at the annual general meeting of the Royal Medical Benevolent Fund on June 12, referred to a proposal, which was assuming practical shape, for the provision by the Fund of homes for old and infirm members of the medical profession or their dependants. As a beginning, a house had been found in Putney which admirably fulfilled the ideas which the committee had in mind, and it was hoped in a month or so to announce the completion of the purchase. It would provide accommodation at an extremely small rental for about a dozen elderly ladies, each of whom would have a comfortable bed-sitting room, and there would be communal sitting and dining rooms and access to the garden. If this initial scheme was a success it was hoped to extend it by providing other houses for married couples or for a larger number of single people of either sex. The project was an ambitious one, but to carry out the complete scheme would cost a great deal of money, and the extent to which it could be enlarged by buying more property, and building perhaps a small nursing home, depended upon the generous support of the profession. He added that the residences would not be called "homes" or given any label which signified that the occupants were recipients of charity.

Position of the Fund

In reviewing the general position of the Fund Sir Arnold Lawson said that the number of subscribers was now in excess of all previous records; legacies had been more abundant than ever; the Christmas gifts appeal had risen to a new level of over £2,000, and "on all sides there are indications that our profession increasingly recognizes what we stand for and is desirous of taking part in our efforts." Those who were concerned with a charitable fund must necessarily

be very much aware of the present tendencies towards State control and the taking over of endowments. It would be a tragedy if the Fund were to be merged into the general structure of a national social service or made subject to the whims of a Government Department. The nationalization of charity meant inevitably the restriction of private giving.

Sir Arnold Lawson was re-elected president of the Fund, with Dr. C. L. Bateson as treasurer, and Mr. R. M. Handfield-Jones as honorary secretary. The resignations of Sir Alfred Webb-Johnson, Dr. N. G. Horner, and Dr. Z. Mennell from the Committee of Management were accepted with regret, and Prof. G. Grey Turner and (representing the Medical Women's Federation) Dr. Frances Huxley were elected to the committee. Thanks for continuing help were expressed to the Ladies Guild, the British Medical Association, and its Charities Trust Fund, the Medical Insurance Agency, and the medical press.

MEDICAL BIRTHDAY HONOURS

The names of the following members of the medical profession were omitted from the list of Birthday Honours printed last week at page 961: Robert Benedict Bourdillon, M.C., A.F.C., D.M., Director, Electromedical Research Unit, Stoke Mandeville Hospital, Medical Research Council, was appointed C.B.E. (Civil Division); Surg. Capt. James White Thomson, M.B., Ch.B., British Guiana Garrison, M.B.E. (Military Division); and Rai Bahadur Kanan Bihari Sen Roy, M.B., B.S., Deputy Inspector-General of Civil Hospitals, United Provinces, M.B.E. (Civil Division).

Correspondence

The Population of India

SIR,—Dr. B. H. Kirman (June 8, p. 890) states that it appears to him "at once fantastic, inhuman, and unscientific to describe India's problem as an excess of population." A few years ago only a very small number of persons would have come within the scope of this scathing indictment, but recently there has been a remarkably rapid change in the outlook on the population problem, so that to-day most of the leading experts in public health, economics, and sociology in India are committing the offence which has aroused such feelings of indignation.

Startling evidence of this change of outlook is found in the very important report just issued by the Health Survey and Development Committee, which was appointed by the Government of India in October, 1943. A distinguished Indian, Sir Joseph Bhore, was the chairman of the committee; 19 of the 25 members were Indians, the rest were Europeans. Most of the members were prominent experts in medicine and public health, but seven, including the chairman, were laymen. The Indian members were fully representative of all the great religious communities and of every shade of political opinion. After more than two years spent on intensive survey and inquiry, the committee have now produced a comprehensive report on every aspect of health conditions in India. In the section dealing with the population problem the following passages occur:

"The question of the need for a continued adjustment between the population and the resources that are available cannot be ignored and should receive serious consideration." . . . "It has been the experience in more than one community that, under favourable conditions, the population doubled itself in about 20 to 25 years." . . . "If our proposals are carried out there is every reason to believe that there will be a saving of at least three million lives every year in British India." . . . "Under such conditions the very large increase of 83 millions which took place between 1921 and 1941 is likely to be reached within half that time. A purposeful control of mortality without a corresponding fall in the fertility rate of the community can thus have far-reaching consequences." . . . "A limit to economic productivity will be reached, sooner or later, and uncontrolled growth of population must, as far as we can see, outstrip the productive capacity of the country." . . . "We feel that the only practical steps that can be taken are: (1) a relentless pursuit of the measures that are now being proposed for the reconstruction of the national life in order to raise the standard of living, and (2) the spreading of the knowledge of birth control, as far as the limitations imposed by the peculiar circumstances of the country, to which we have referred, will permit." . . . "We consider it highly desirable that the population problem should be the subject of continuous study."

A remarkable feature of this momentous report is that it was almost unanimous; of the 19 Indian members of the committee only one found himself "unable to subscribe to some of the recommendations," and of the 6 European members only one dissented from the recommendations on the population problem. Neither of these two dissenters has given any reasons for his disagreement. No further comment is needed on the letter of Dr. Kirman or on the other recent letters from writers who have argued either that there is no population problem in India or that, even if the problem does exist, it must not be discussed lest the susceptibilities of the people of India should be offended.—I am, etc.,

Hawthorn, Kent.

J. W. MEGAW.

Fibrositis and Prolapsed Disk

SIR.—Following the paper by Prof. Arnold Sorshy and Dr. A. Gormaz (April 20, p. 597) I wrote a letter (May 18, p. 774) in which the main plea was for the abolition of the term "rheumatism" or for a more limited definition. In his reply to my letter Mr. J. S. Maxwell (June 8, p. 889) was taken up by two side issues—namely, "fibrositis" and prolapsed intervertebral disk, though, in fact, prolapsed intervertebral disk was never mentioned by me. With regard to his remarks on "fibrositis," Mr. Maxwell is an orthopaedic surgeon, and in that stormy torrent of medical practice there is perhaps little or no time to devote to the careful study of many painful conditions, especially those whose pathology is unknown and whose recovery is invariable. Like him, I have suffered from pain about the right shoulder which recovered spontaneously, though, unlike him, I would not be prepared to say that it was limited to or in any way related to the trapezius muscle, nor, in my case, was it connected with temperature changes or open windows. Whether or not this constitutes a "clinical entity" I do not know, but I suggest that there is no proof that such a pain is in any way related to fibrous tissue, nor indeed that it has an inflammatory basis. I would not go so far as to suggest that my pain, still less his, was psychogenic, but I notice that Mr. Maxwell does not comment on my statement that the bulk of cases labelled "fibrositis" are, in fact, examples of psychogenic pain. Like him, we have all seen people with sciatica, or almost any other malady, who attribute their troubles to sitting in a draught, though this aetiological "fact" is probably more often than not in the same class as being "dropped on the head when a baby," or being "scratched by a rusty nail," and the absence of abnormal signs, and the spontaneous recovery, do not, to my mind, in any way prove the patient's contention.

I should not have thought that there was any fashionable tendency to label conditions "prolapsed intervertebral disk" which were previously labelled "fibrositis," with the sole exceptions of those complaining of sciatic pain or "brachial neuritis" with their almost invariable accompanying signs. I understand that one of the commonest sites for "fibrositis" is the scalp, and I have never heard of a scalp pain being attributed to a prolapsed cervical disk. I would agree that a prolapsed disk has not always been found at operation in cases of sciatica, though I think such negative exploration has become increasingly infrequent during the past few years; such a state of affairs has probably applied in the past to every pathological condition which has become amenable to surgery. In both sciatica and so-called "brachial neuritis" the importance of a prolapsed disk as causative factor is now well established.—I am, etc.,

Leeds.

HUGH G. GARLAND.

The Spread of Infection

SIR.—The article on nasopharyngeal infections by Dr. Ronald Hare and Miss Dorothy Mackenzie (June 8, p. 865) and the letter on influenza and cholera by Dr. J. Walker Tomb (p. 887) show a commendably alert attitude to epidemiological problems. The writers contend that there is much more to understand in the variation of virulence in bacteria and viruses and the alterations of resistance in the tissues than has yet been realized. The rather simple belief that epidemics can be equated in terms of a species of organism known to produce disease in some circumstances and a human being lacking in antibodies to that species has been given too much assent because the two factors mentioned are comparatively easily ascertained. Latent infection and the rise from it of endogenous disease in

the carrier and exogenous disease in others are subjects which may be better understood by extensions of Shope's work on the non-infective form of the swine influenza virus found in the lung worm. These results are quoted by Hare and Mackenzie and by Tomb, who also refers to his own published conclusions that the alteration of cholera vibrios in the human intestine from a non-infective to an infective form is important in the cause of epidemic cholera. Systematic study of bacteria and viruses will be needed with a receptive and critical outlook, and it is hoped that this will be hastened by the Society for General Microbiology which was formed last year. There have been for some years carefully prepared results in this field which are too much ignored. One of these is the occurrence of the G forms of certain organisms (P. Hadley, *J. Infect. Dis.*, 1931, 48, 1), which vary so much from the forms usually recognized that they have been left out of account in the study of diseases caused by better-known forms. Confirmation of much of this work has been given by other workers, including, in this country, A. Haddow (*J. Infect. Dis.*, 1938, 63, 129). Another result is the conversion of pneumococci from one type to another *in vivo* and *in vitro*; this fact needs special consideration because the change is made from an avirulent pneumococcus to a virulent one of another type. The beginning of this latter work was made by the late Fred Griffith (*J. Hyg.*, 1928, 27, 113) in this country, but the development of it has been left to American bacteriologists. The occurrence in your *Journal* of the article and letter to which I have referred indicates, I hope, that fresh knowledge will soon be sought and welcomed in studies of epidemiology.—I am, etc.,

London, N 19.

J. M. ALSTON.

Spread of Nasopharyngeal Infections

SIR.—St. Kilda provides further and earlier evidence in support of the theory of indirect transfer of nasopharyngeal infections discussed by Dr. Ronald Hare and Miss Dorothy Mackenzie (June 8, p. 865). In 1697 Martin Martin, a native of Skye, M.A. of Edinburgh University and later M.D. of Leyden, visited the island. In his *Voyage to St. Kilda* he records that the inhabitants always contracted a cough when the steward and his retinue from Skye paid their yearly visit, and whenever any strangers landed and stayed for any time. The cough, very productive of sputum and lasting ten to fourteen days, affected all the islanders. Infants at the breast were very subject to this cough, a fact brought forward to convince Martin, who at first considered the notion of infection fanciful. When any foreign goods were brought there the cough was of longer duration than otherwise. Martin does not say that the visitors were free from cough, but in view of his reluctance to admit that the islanders' theory was correct it is probable that they were, in fact, free, for elsewhere he says that if the fever had been among those of the steward's retinue, even before their arrival in St. Kilda, some of the islanders were infected. After the infected cough was over, neither young nor old among the strangers and inhabitants of St. Kilda did so much as cough once more, though frequently assembled for divine service.—I am, etc.,

Southampton.

W. P. CARRILL.

Smallpox in the Vaccinated

SIR.—Dr. C. Killick Millard (June 8, p. 890) is correct about the soldier. He had been successfully vaccinated and revaccinated and he was the cause of the outbreak. Though it does not necessarily follow that this was because he was a mild case, for cases in Southend were caused by a virulent unvaccinated case to whom no doctor was called as it was thought to be a case of chicken-pox.

Dr. Killick Millard appears to advocate no vaccination until cases occur. Surely he would not include troops going to India. If he considers these should be vaccinated I cannot follow his reasoning, as if troops for India should be vaccinated so should civilians going to India, so that always there will be a risk of the missed, mild, modified case of variola. Perhaps Dr. Killick Millard will agree with this, but holds that people in Great Britain should not be vaccinated until an outbreak starts, on the grounds that an immediate virulent case or two will readily be diagnosed and so a widespread epidemic will be prevented at the cost of only a few deaths. Surely, recent outbreaks have proved this contention to be incorrect. Mild modified

cases in a number of instances recently have been readily diagnosed and outbreaks have not been widespread. The alternative appears to be between an unvaccinated population and a risk of some deaths and *perhaps* a very limited outbreak. That seems to be Dr. Killick Millard's choice.

On the contrary, I prefer a vaccinated population, even without revaccination (though this should be advised), few deaths, if any, and *perhaps* a rather more widespread outbreak of modified cases. I do not agree that the size of the outbreak at all necessarily depends upon the type of the first cases. I wonder if Dr. Killick Millard would apply the same reasoning to immunization against diphtheria?—I am, etc.,

Health Department, Colchester.

W. F. CORFIELD.

Naples Typhus Epidemic

SIR,—Your issues for April 13 (p. 579) and May 4 (p. 700) contain, respectively, an article by Lieut.-Col. H. J. Craufurd-Benson and a letter by Col. H. D. Chalke on the Naples typhus epidemic in which certain inaccuracies occur which I am anxious to correct.

It will be appreciated in the first place that the epidemic was a civilian affair and, as such, the first brunt of it fell on the Allied Military Government organization of the Fifth Army, then established in Region III with H.Q. at Naples. I took over as colonel, Public Health and Welfare, on Dec. 3. Lieut.-Col. Chalke was then A.D.H. at Adv. Admin. Echelon, A.A.I., and was neither the "Senior Hygiene Officer in Naples" nor directly concerned with the epidemic.

Drs. Soper and Davis of the Rockefeller Foundation, to whom the greatest part of the credit for the control of the epidemic is due, were sent over to me by N.A.T.O.U.S.A. At no time did they "work alone." I had the privilege of having them working with me as part of the organization I was then building up in A.M.G. to fight the epidemic.

Col. Chalke refers to "the whole-hearted co-operation of British and American medical services" and to "the pooling of resources." For the sake of accuracy it should be known that everything A.M.G. required to fight the epidemic in those early December weeks had to be begged for, or borrowed (with difficulty), or even stolen! A request made by me for insecticidal powders on Dec. 3 was refused—if not treated with scorn. Other than the few decrepit cars obtained from the Italian authorities (who played 100%), I found it impossible to get any transport for the dusting and case-finding team from the Army. As another example of "whole-hearted co-operation" a reference had to be made to the highest possible authority to get the R.A.F. out of the only infectious diseases hospital in Naples. It was not until the U.S. Typhus Commission came in armed with full authority to demand anything they wanted that the resources of the Armies in men, transport, and material were placed at their disposal. The U.S. Commission took over the organization established by A.M.G. on Jan. 3, and expanded it, but the epidemic had already been checked by A.M.G., as the drop in incidence on Jan. 9 and the subsequent steady decline showed.

Because of the refusal of insecticidal powder in the beginning steam disinfection was used—but only on a minor scale because of the immense difficulties met with in finding the required materials in the shattered city. We did succeed in opening centres at the Albergo dei Poveri, at the Pace Hospital, and at the Ospedali Riuniti. They were used until the dusting powders became available.

The first public dusting centre was opened at the railway station on Dec. 15. MYL was used merely because of the difficulties experienced in finding grinding and mixing machinery. D.D.T. was brought into use about ten days after the first dusting, scarcely "relatively late" in the epidemic. D.D.T. is the insecticide of choice because of its prolonged action. MYL was a useful stop-gap which was backed soon after by D.D.T.

If there is one lesson to be learnt from the Naples epidemic it is the absolute need for Military Government in the field to have an equal priority in bidding for men, transport, and material as any other organization in the field. This lesson had not been fully appreciated in N.W. Europe, where I was Director, Public Health, A.M.G., 21 Army Group. It would have saved valuable time in both theatres of war.—I am, etc.,

Nagpur, India.

W. H. CRICHTON.

Hernia and Strain

SIR,—Mr. Stephen Power (June 8, p. 888) adds his testimony to the growing belief that the transversalis fascia is of primary importance in the aetiology of inguinal hernia. He implies that in young men the repair of these herniae should be limited to removal of the sac and suture of the torn fascia, deploring the "building up" of "a barrier at an anterior level." His wording is a trifle ambiguous, and that the operation should be limited to suture of the transversalis fascia and reconstitution of the remaining structures may not be his meaning. For my purpose this ambiguity is of little importance. What is important is that Mr. Power gives operative advice based on anatomical observations without reference to his results. I submit that this is not good enough. In this matter one cannot hope to carry conviction without figures. I do hope he will repair this omission.

That the "barrier at an anterior level" can be an effective barrier was, I think, demonstrated by the late results reported by Mr. J. T. Morrison and myself at the recent meeting of the Association of Surgeons. We quoted 230 unselected adult inguinal herniae of great variety, with recurrence in 4. In all of these cases the sac was removed and the canal repaired (without previous suture of the transversalis fascia) with a strip of aponeurosis taken from the external oblique in the manner strongly advocated these many years by my collaborator.—I am, etc.,

Liverpool.

CHARLES WELLS.

SIR,—Mr. Stephen Power (June 8, p. 888) has described a very important factor in the anatomy of hernia. He points out the existence of a hole in the fascia transversalis at the internal ring, and stresses the importance of its closure after the sac has been ligated and removed. I feel sure that if this procedure is not carried out during the repair of a hernia the chances of recurrence are very much increased. If this opening in the fascia transversalis is left patent the stump at the sac directly behind it has no barrier to prevent it bulging through the opening when the patient strains, and so extending itself forward and becoming elongated to give rise to a new sac formation.

I feel that the existence of the hole in the fascia transversalis in inguinal hernia has not been described fully in the textbooks on hernia. In fact, many herniotomists are not aware of its existence. During the meeting of the Association of Surgeons in London in May, when a discussion on hernia took place, no mention was made by any of the many speakers of the existence of a hole in the fascia transversalis and the importance of its proper closure. While performing a radical cure on hernia, I always make it a practice to point out the opening to my assistant by placing my forefinger into the opening prior to sewing it up. The size of the hole is very variable. In some cases it can admit two fingers, and one can see how far medially the deep epigastric vessels are displaced. The opening in the fascia should be closed by means of a continuous suture, just enough room being left for the cord to emerge.

As regards the suture materials used in the repair, I am of the opinion that this is not so important. I have used Chinese twist, floss silk, fascia lata, buried nylon in the form of a filigree, and even skin strips. It is the method of repair that counts and not which suturing is used.

Lastly, I should like to mention one other point which I consider important in order to prevent recurrence. This is to alter the course of the cord after it emerges from the internal ring. Normally the cord after its emergence passes down the canal medially and caudally. It is advisable, I consider, to make the cord pass upwards and laterally before passing downwards and medially. In this way a hernia, should it attempt to recur, finds its path of exit from the internal ring more difficult. I learnt this tip from Mr. Rodney Maingot, and I think the principle of it is very sound.—I am, etc.,

London, W.1.

MAURICE LEE.

Old Age and Calories

SIR,—Among the problems connected with the subject of old age there is one that seems to me worthy, so far as possible, of special investigation. I refer to calorie value of the diet during the prime of life. It has been suspected that a very high calorie value—especially excess of meat—tends to shorten life, death

occurring at between, say, 60 to 70 years of age instead of between 70 and 80. It would be very interesting if dietetic investigations could throw light on this subject. Even during my life-time habits seem to have changed considerably, much less meat being consumed by well-to-do men in the prime of life (I refer, of course, to ordinary times of peace). The metabolic and excretory organs (especially the kidneys) are presumably less constantly overworked, and maintain their proper functional activity to a later period of life; this may partly account for the modern increase of old persons with normal mental powers.

Is there any reason for endeavouring to increase the number of old persons? Yes, I think so. One of the chief advantages of healthy old persons in a community consists, I believe, in their accumulated knowledge and resultant *doubt*. "Doubt grows with knowledge" (Goethe), and knowledge should increase with age. Old persons, owing to their knowledge and *doubt*, should be less prone than the young to that kind of "fanatical certitude" which provokes enmity, aggression, and war.

As to the effects on the chances of longevity of a relatively low calorie value of diet during early and middle life very little, I believe, known, though unfortunately, especially at the present time, much is known about the immediate disastrous results of grave undernutrition.—I am, etc.,

London, W.1.

F. PARKES WEBER.

Artificial Respiration

SIR,—Prof. R. R. Macintosh and Dr. W. W. Mushin (June 15, p. 908), comparing the efficiency of different methods of artificial respiration, state that too much stress has been laid on details and not enough on essentials, such as a clear airway. They say that the choice of method is relatively unimportant. This is true, with one qualification—that the method is properly carried out. This sounds foolishly obvious, but there is one method which is often used badly and inefficiently.

In respiratory failure during or after anaesthesia the patient is normally lying on his back and the most convenient method is Schäfer's (direct pressure on the chest). If this pressure is applied too low, which is a very easy mistake if the surgeon is doing it from his normal position, it falls entirely on the liver and the effect on the lungs is practically *nil*.

Illustrative Case.—A stone in the ureter was removed from a soldier in a German prisoner-of-war hospital. He stopped breathing after his return to the ward. The cause was probably the combined depressant effects of morphine, evipan, and ether. (The only available apparatus for dealing with these tough male adults was an open ether mask, which is rather like shooting elephants with an air-gun, so we often gave undesirably large doses of preliminary drugs.) It was not my case, but I was called in. I found the surgeon energetically using Schäfer's method, but no air was entering or leaving the lungs. Putting in an airway made no difference. The oxygen apparatus arrived from the theatre at this moment. Now the German Army portable *Sauerstoffgerät*, though fitted with multiple breathing tubes and face-pieces for treating four patients at once, has no provision for giving oxygen under pressure. The bag of the apparatus confirmed the absence of pulmonary ventilation. So, telling the surgeon to do a rapid wash-up for a cardiac massage, I continued the artificial respiration by pressing with one hand on the sternum. This immediately caused a free flow of oxygen in and out.

The anaesthetist's normal position at the patient's head makes it practically impossible for him to make the mistake of pressing too low down. Pressure on the lower ribs may be all right if the patient is lying prone, but it is certainly useless when the patient is lying on his back. It would be interesting to have this point confirmed by spirometer readings during anaesthesia.—I am, etc.,

Leeds.

W. STANLEY SYKES.

The Catheter and the Prostate

SIR,—The letters from Dr. Seymour Edelman (June 1) show that the abstract of my paper was too condensed to be lucid. The acute prostatic retention should be operated upon as an urgency and the pain immediately relieved by morphine; or, if the waiting interval is too long—as in a patient who travelled last week from Devon to Manchester—by the suprapubic insertion of an aseptic lumbar-puncture needle attached by a

rubber tube led into a sterile bottle. These methods are less painful than catheterization and do no damage to the delicate urethra. The preparatory chemotherapy is intramuscular.

There are no more misleading statistics in medicine than those in connexion with prostatectomy. I refused to operate upon 8 out of 573 cases (1.4%), and there were no pre-operative drainage deaths because I do no pre-operative drainage. This suggests a higher standard of operability than any yet recorded. Mr. H. P. Winsbury-White (June 1) refused (so far) at least 18 cases out of 113 (15.9%). If one were to pick one's cases I presume that the mortality might be *nil*. Mr. Clifford Morson (June 8) makes comparisons between my figures and those of the late Sir Peter Freyer which are misleading because they are incomplete: he is unaware of the number of cases Freyer refused and left to die, but he is well aware of the appalling mortality of simple suprapubic drainage in those days, before even slow decompression came into practice. Until we know the numbers of cases refused, the mortality of the preliminary drainage, and the ultimate after-condition of the patient, we can form no opinion of the value of the various methods of prostatectomy; and the simple prostatectomy mortality figures with the pre-operative drainage mortality statistics concealed are valueless. If Mr. Winsbury-White will do his prostatectomies aseptically he will see absolutely clear urine every day, though not in every case.

My removal of the greater portion of the trigone is described as a "physiological mutilation of the trigger of micturition." Well, I do not know of any old man, passing urine many times at night, who would not be glad to get rid of his "trigger." I strongly suspect that the absence of the trigone is the reason for the lesser frequency of micturition after my operation than after those done by me by the retropubic route.

History will show that the catheter and suprapubic drainage, and the shibboleth of slow decompression, have put back the clock of prostatectomy by thirty years, and have caused the birth and spread of septic transurethral resection with its imperfections and complications.—I am, etc.,

Manchester.

WILSON H. HEY.

SIR,—The mortality rate for simple suprapubic cystostomy in my recently mentioned prostate cases was 2 in 73 cases (2.7%) not 11.1%. Dr. Terence McCall (June 15, p. 931) seems to have overlooked the 55 cases of cystostomy which proceeded later to the second stage of prostatectomy.—I am, etc.,

London, W.1.

H. P. WINSBURY-WHITE.

Treatment of Sterility in Women

SIR,—Many women are now seeking help because of sterility, and the investigations of this complaint have now reached a high standard of efficiency, but is it possible that the investigation is outdistancing treatment? I find that patients all over the country are having their tubes inflated or made opaque by lipiodol, and then being sent away under the impression that pregnancy will shortly follow. Surely all the gynaecologist can say after such a manoeuvre is, "Provided I have not done any damage, you are just the same as you were before." It is amazing how many people seem to forget that the operation of dilatation of the cervix is still the most important factor in the treatment of sterility.—I am, etc.,

Leeds.

DAVID CURRIE.

Notification of Venereal Disease

SIR,—A full system of notification and compulsory examination and treatment, as Dr. C. M. Ockwell (June 15, p. 929) reminds us, still awaits official acceptance in this country. Although Regulation 33B is an inadequate compromise, its introduction implies Government recognition of the need for compulsion in certain circumstances. This Regulation has proved useful, but its value in V.D. control could be augmented greatly by extending its provisions so that official action could follow the receipt of one notification. This step would, in my opinion, be more simple and effective than seeking the inclusion of the venereal diseases among the notifiable infectious diseases referred to in the Public Health Act.—I am, etc.,

Ipswich.

S. M. LAIRD.

Industrial Medicine

SIR,—Whatever views may be held on the merits of artificial sunlight in industry, surely no informed person will claim that physical methods are anything but ancillary to the more radical methods of preventing sickness and absenteeism to which you refer in your leading article (June 8, p. 882). The primary function of industrial medicine is research, directed to the detection and elimination of industrial hazards.—I am, etc.,

Derby.

GERALD F. KEATINGE.

Psychology in the Child's Education

SIR,—The letter from Dr. E. Stungo (June 15, p. 930) stimulates me to make comment. We can easily agree that children are the citizens of the future and deserve the best we can give them, but why is it that when we start planning we so easily start on the wrong foot?

The main suggestion in the letter is to the effect that children should be taught as the Nazi children were taught, only taught citizenship. How easy to say, and how difficult to put into practice! Dr. Stungo leaves out the real source of good citizenship, which is in the life of the child in his own home, including the first relationship, that between infant and mother. On the basis of a good first relationship, more complex relationships can be developed gradually at home, and if all goes well the wider world is approached through the family's external relationships. If these things fail, citizenship (or something else) has to be taught, and a job it is.

If doctors are to interest themselves in this business of producing citizens they can start immediately by refraining from all avoidable interference with infants and small children. Neither should any physical treatment be undertaken that can possibly be avoided, nor should infants and small children be taken from home except in case of dire necessity. Small children in hospitals should be visited so frequently that they never cease to be sad, which means that they do not lose the thread of home life; and they should be sent home as quickly as possible. Moreover, there should be a stop to the general practice of taking over responsibility from parents who would like to retain responsibility: it is possible to give help without in any way making parents feel they are not fit to act on their own judgment.

Doctors and psychiatrists should remember that parents and teachers cannot wait for psychology to get to know everything. Parents and teachers have to deal with whole problems, and this is specially true of mothers with their infants. We understand some very important things about emotional development, but there is very much we do not yet know, or but dimly see. Let us not imagine we can tell a mother how to be a mother or a teacher how to teach. We can help each to understand this and that, and we can make their mothering and teaching jobs more conscious and more interesting; but all the time parents and teachers will have to carry on intuitively and without being able to account for all that they do.

Dr. Stungo says "children learn something of love, charity, sacrifice, humility, modesty, good and evil from religious instruction . . . they should be taught to appreciate the nature of hate, envy, greed, spite, guilt, and temper. . . ." In my opinion children know more about all these things than we do, and we could spend our time letting them teach us with a good deal of profit.—I am, etc.,

London, W.1.

D. W. WINNICOTT.

SIR,—Dr. E. Stungo deserves credit for drawing attention to educational affairs of utmost importance, both national and international. Surely, the medical profession must not lose sight of its long-established educational function within the community. While child psychiatrists will find themselves in hearty agreement with the general line of Dr. Stungo's striking observations and far-sighted demands, there are, on the other hand, some points in relation to his statements which require further elucidation. Modern child psychology distinguishes certain "phases" in the normal development of the child, each of them having great biological importance. It is, therefore, not quite appropriate to use the slogan "A child ought to be taught . . ." unless one refers to a certain phase or age in the child's development. Unfortunately, this point of view has been omitted from Dr. Stungo's remarks. There are phases in the

child's development in which psychological enlightenment in the sense of training would be entirely out of place. Nature has provided the child, for a certain span of his life, with a precious gift—viz., "naivety" (but for processes in his unconscious). It would be unwelcome to all concerned to deprive the child of this gift by guiding him towards precocious introspection and assessment of "fellow men." Child psychiatrists know how often the untimely destruction of a child's naivety by events in his home—or outside it, for that matter—can lead to a neurotic development. I had to utter a similar warning a few years ago, when a psychologist in a book on children's development recommended some sort of "confession," which the child had to make every night to his father or mother sitting at his bedside, on wrongs he had done during the day. It should be realized what a "neurotizing" effect a surplus of introspection at an early age can have. No harm can be done by guiding children aged 10 to 13 to a correct and alert observation of people, by ways and means for which the Boy Scout system can be an example. The first approach of the child to "systematic" psychology should be, to use a modern term in psychology, "behaviouristic." With the approach of puberty the child becomes naturally introspective and at the same time very much concerned with the motives of people's actions and conduct. It is at this stage that terms of structural and deeper psychology can be brought, gradually and unobtrusively, to the child's mind. This is the age in which, as Dr. Stungo rightly expects, the endeavour to understand other groups and nations should find a fertile soil.

Some of Dr. Stungo's remarks are directed against "frustration" in the child's life, created by competitive systems in education. It is not frustration itself which is noxious or to be feared, but a surplus or an overwhelming intensity of it. Without frustration the development of a child's character would be as "shallow" as an adult's development without inner conflict.

The most practicable part of Dr. Stungo's remarks is where he speaks of the teacher's training in child psychology. That teachers should be trained, in addition to the facts of normal development, also in the recognition of developmental difficulties and behaviour disorders, just sufficiently so as to guide those children into the proper medical channels and to co-operate in their treatment, cannot be enough underlined. The best solution would be to allot some time in the curriculum of trainee teachers to such child psychiatrists as would be willing to co-operate in a direct way within the educational system. It can be safely said that while our age and society tend to exclude waste in every possible sphere, the sphere where most waste and frustration is still tolerated is that of psychic economy and mental hygiene. Surely, if society wants to overcome this state and to prepare for an age of better social adaptation, new ways must be found in order that new sap, provided by medical knowledge, may reach the roots of our educational system.—I am, etc.,

Virginia Water.

STEPHEN KRAUSS.

The Health Bill and Medical Research

SIR,—I have read the contents of the White Paper and the various Parliamentary debates connected with it, and can find no reference to that fountain-head of medical progress—namely, medical research. This is the more surprising since vast sums of money have been pledged to atomic research and other destructive agents, and I can find no mention of similar sums being set aside for the saving of human life in the field of preventive medicine and associated research. In fact I quite agree with Drs. Hilton and Luntz (June 1, p. 850) that the only available sums amount to some £215,000 per annum for the whole of the British Isles.

It is popularly assumed by Parliamentarians and public alike that anyone can undertake medical research. This, I maintain, is far from the truth: a trained research worker is very much like a judge, and requires much the same mental outlook. Just as a judge requires a comprehensive knowledge of the law so the trained research worker requires a vast knowledge of comparative medicine and, in addition, a comprehensive knowledge of international research literature. In preparing his paper he has to act not only as counsel for the prosecution but also as counsel for the defence, and jury, and, by mental cross-examination, build up his thesis or "summing up."

I can well foresee the time when those who spend some time on unpaid medical research will, when the Bill is made law, drift into the more secure and more lucrative harbours of a full-time salaried appointment under the State, and medical progress will retrogress.—I am, etc.,

Northampton.

JOHN H. HANNAN.

"A Doctor's Charter"

SIR.—Dr. Edith Summerskill, addressing the Labour Party Conference, is reported to have described the Health Service Bill as a "charter of liberty for the medical profession," explaining that "in future no doctor need prostitute his science by pandering to the hypochondriac." I suppose that in the circumstances in which she made it this astounding statement was taken for sober truth, and raised not even "cries of 'Oh.'" The *Times* has had the grace to print a well-deserved comment on it by Dr. Alfred Cox, but even his letter does not, I think, do full justice to its extreme perversity. I can imagine situations in which it might be genuinely difficult for a doctor to rid himself of an unwanted hypochondriac. A Lord of the Manor or popular trade union leader or, in future, a chairman of a Regional Board, if thus afflicted, might, in an over-organized community, be hard to shake off without undue loss. But such cases, if they occur, can scarcely be affected by an Act of Parliament. What matters is not the exceptional but the ordinary hypochondriac.

In a community of free individuals accustomed to pay direct for medical attention nothing is easier than to avoid this "privatization of medical science." A lifted eyebrow, a well-judged silence, a lack of enthusiasm for the latest thing in therapeutics and the bird will fly. Moreover, the bird is gregarious, and others of his feather or hers will fly too or keep away. In the conditions of free private practice such patients can be collected for investigation and treatment or avoided at will. Plenty of work of other kinds and a decent livelihood remain for those of us who prefer to avoid them; doctors and patients alike tend at least to get what they desire and, it may well be, what they are most fitted to do or to receive.

But when every hypochondriac has already paid his fee by way of compulsory contribution; when he has a right to "the best" for the asking and is officially urged to take every "early symptom" to the doctor forthwith; when he may be allotted by a committee to a reluctant practitioner deprived of the right to raise his fee or to request the patient to choose another doctor; then I fear, if we enter the service, we shall learn what it is to be at the mercy of these unhappy but exhausting folk. Or if, following Dr. Summerskill's lead, the whole service steels its heart so that they cannot get "twixt the lawful sheets" the recurrent investigations and treatments their souls desire, then must arise a medical or quasi-medical "black market" hitherto unknown, and in that market medical science will indeed play the prostitute.—I am, etc.,

Hampstead, N.W.3.

LINDSAY W. BATTEN.

Health Service Bill

SIR.—I am certain that a large number of medical men must feel, as I do, increasing apprehension at the present policy of the B.M.A. with regard to the new health Bill. However you may look at it, organized refusal to work the Bill is a strike, and it is just because I am a lifelong Conservative that the idea of a direct action strike against the Government of the day is repugnant to me, and I, personally, will take no part in it, however much I disapprove of the Government's policy. Such a strike, reprehensible enough when undertaken by miners, transport workers, etc., is doubly so when threatened by an educated section of the community like the medical profession.

There is now little doubt that the great majority of the people are in favour of the Bill, and doctors who think otherwise are merely indulging in the good old habit of "wishful thinking." The people frankly do not understand what the doctors are making a fuss about, but the seeds of suspicion are being sown that the doctors are intent on getting their money to the exclusion of everything else. Let us do all we can by constitutional means to get what we consider to be the best conditions for all concerned, but do let us stop these foolish threats to strike which are rapidly bringing the profession into disrepute.—I am, etc.,

Diss, Norfolk.

J. V. DOCKRAY.

SIR.—I am one of the many doctors who view with misgiving the Government's proposals for a National Health Service, but I have been almost converted in its favour by the pamphlets recently published by the B.M.A. for distribution by doctors to their patients.

Space will permit mention of only the grosser absurdities in these circulars. In one of them the following underlined statement appears: "*Under the National Health Service Bill your doctor may be told how to treat you by Government circular.*" Does any intelligent person believe that such a possibility exists and is there any justification for the suggestion? In the Forces, to which disparaging reference is made in another circular, it is true that "directives" were issued from time to time, as well as the eagerly read Army Medical Department Bulletins. Both of these contained advice on treatment based on current experience over a wide field; to that extent they indicated "how to treat" the patient. So far as I remember they never ordered a particular line of treatment. They did, occasionally, order a certain line of investigation, and sometimes put a ban upon treatment that accumulated experience had shown to be highly dangerous. It may be suggested that not a few patients might have been spared a good deal had their doctors been "told how to treat" them in this way.

In another pamphlet statements by Sir William Beveridge and the Government actuary are quoted, and the reader is asked to "note the distrust of the doctor shown" in them. Both statements emphasize the necessity for a high standard of certification, and one suggests that "there may be a tendency on the part of doctors to require longer periods off work" for their patients. Are we, then, so thin-skinned—or is it a sense of guilt—that we wince at the mention of "careful certification"? And does not experience of the working of N.H.I. suggest that the Government actuary's fear of "longer periods off work" is, at least, well founded?

Finally, a paragraph of barely veiled innuendo referring to doctors in the Forces ends with the sentence: "The task of the Forces doctor is to make all ranks fit for duty and to protect the pensions fund." Success in the second of these tasks follows largely upon success in the first, and both seem to be eminently desirable. If a National Health Service can bring about such a happy state of affairs, then the sooner it is in force the better.—I am, etc.,

Newcastle-upon-Tyne.

A. ANGUS.

Assistants and the Bill

SIR.—In my letter (June 1, p. 847), I listed five general respects in which the introduction of an assistant into a practice conflicts with the so-called Principles of the profession. Now, although these items clearly relate to matters of fact, Dr. R. McIntosh (June 15, p. 928) endeavours to convince us that they are subject to a vast difference in point of view which he assumes exists between him and myself. Although for some reason he presumes that I have a sordid conception of the relations between principal and assistant, it would appear that his views on that matter are the same as mine. I entirely agree with his three classes of assistants, and join with him in his whole-hearted condemnation of the "grasping principal." He had absolutely no excuse for any assumption to the contrary. I can only suppose that he found nothing to burn in my letter and so had to resort to this rather doubtful method of producing a guy upon which to release the heat of his annoyance.

Having survived this burning in effigy, may I be permitted to restate the fact that, for whatever motive an assistant is employed, it is customary for conditions of his employment to run contrary to the recently adopted Principles of the profession. In fact, at the outset an agreement is usually signed which gives the employer powers of direction far beyond anything contemplated in the present Bill. Another constant feature of such agreements is the acceptance of a salary by the assistant and an undertaking that the doctor employing him shall receive all the assistant's earnings. Both parties are in fact prepared to abandon the precept that remuneration shall be proportionate to effort. While still leaving my views on this doctor-assistant-patient relationship to the guesses of Dr. McIntosh, it may be said that for the most part it is a necessity under the present system. However, my purpose was not to criticize this relationship but to examine its apparent incompatibility with the Principles.

It is obvious that any doctor fundamentally convinced that both salaried service and direction were bad would not be party to any agreement involving any infringement of these Principles. Then one must ask how has it come about that doctors who for many reasons have employed assistants under conditions conflicting with the present avowed Principles of the profession are among those now upholding these Principles when the Government threatens to ignore them to a comparatively slight extent? I am of the opinion that this paradox arises out of some confusion in the interpretation of the word "principle." The Principles are in fact a codification by the B.M.A. of our present relationship with the public, and are put forward by those who are against fundamental change as the frontier upon which they are prepared to stand and fight. That attitude may be unreasonable or hopeless, but it is not necessarily at all dishonest. The latter element is being introduced by those who attempt to invest the Principles with a generalized and almost sacred significance, which is incidentally incompatible with any desire to uphold or retain the present doctor-assistant-patient relationship. To avoid charges of dishonesty doctors should therefore take care to distinguish between the principles of the profession and the recent codification of the Principles of the profession's present struggle against changes involved in the Bill.—I am, etc.,

Eye, Suffolk

J. SHACKLETON BAILEY.

Artificial Sunlight in Industry

SIR,—Dr. Schmidt (June 8, p. 890) criticizes my comment on his statement that ultra-violet irradiation had reduced sickness absence in a colliery by 18%. He based this conclusion on the fact that in the year in which treatment was given at one colliery, Kirkby (Notts), there was 18% less sickness than in the previous year, when there was no treatment, while at one other colliery, where there was no solarium, the rate actually rose. From these facts Dr. Schmidt deduced that the ultra-violet treatment was responsible for the improvement at Kirkby.

Dr. Schmidt is mistaken in thinking that in quoting his figures I compared the "absolute mean sickness figures" of the two collieries. My argument was that, as the sickness absence rates in the two were very different in the year before the irradiation started, a comparison of the changes in their rates in the two years was not valid. Yet Dr. Schmidt based his conclusion on this comparison. He did not ascertain, by a study of the health records of a control group of unirradiated men selected at random within the Kirkby Colliery, whether influences other than the irradiation had caused or contributed to the drop in the sickness rate. Dr. Schmidt argues that each colliery has its own features regarding absenteeism, that some have high rates, and some have low. That may well be true, but he goes on to say that these "general characteristics remain fairly irrelevant" when trying to judge the influence of one specific factor—i.e., the solarium treatment. But his comparison of the changes in these rates depends entirely upon this assumption of irrelevancy. He gives no evidence that from year to year these general characteristics do invariably remain constant and that there are no yearly variations in sickness absence due to the underlying causes he mentions.

To what extent do they occur in the absence of any specific form of treatment? Extension of such observations in space and time might strengthen his case by showing that in different collieries at different times a fall in absenteeism invariably followed solarium treatment. He merely offers a single comparison, and it is obviously impossible to deduce cause and effect from it. On the other hand, Dr. Schmidt might have given more convincing evidence if he had used an adequate control group with the Kirkby Colliery, for it is possible to draw certain reliable conclusions from a relatively limited inquiry which is well controlled. When experimental conditions are less favourable—as, for example, when comparison is made between one period of time and another, or between groups of subjects living in different environments—the observations must be far more extended.

Far from being "lost in a jungle of statistics," I was fortunate in having the guidance of experts both in the planning and in the interpretation of my experiments.—I am, etc.,

London, W.6.

DORA C. COLEBROOK.

Judicial Responsibility of the G.M.C.

SIR,—In the report (*Supplement*, June 8, p. 165) of the Summer Session of the G.M.C. the President, after announcing the restoration of the name of Dr. Hennessy to the *Register*, is reported to have said that he had been asked by the Council to add a few words. "A judge of the High Court (Mr. Justice Charles), in a judgment delivered by him on April 12, 1946, had intimated that the Council 'not having the advantage of the great mass of evidence that had been put before him and which was not put before them,' had 'in the absence of adequate evidence (and they could only deal with the matter on the evidence before them)' come to a conclusion adverse to the practitioner which had resulted . . . in a gross miscarriage of justice." The President continued: "But I must emphasize that it is imperative in all inquiries held by the Council under Section 29 of the Medical Act, 1858, that an accused practitioner should call before this Council all material and relevant evidence in support of his case. *If he neglects to do so, it is at his own peril*" (italics mine). "This Council can only deal with any case on the evidence before them. If there is evidence that is relevant and that could be adduced on behalf of the practitioner and is not so adduced, the responsibility of any adverse view by the Council *must rest with the accused practitioner*" (my italics).

I would make the following observations: (1) Evidence given before the G.M.C. is not given on oath and is not evidence in a legal sense. (2) Neither the Council, the complainant, nor the accused practitioner has the power to subpoena witnesses, and it follows that even the unsworn evidence may be incomplete (and a material witness may be unwilling to attend to give evidence because of the time involved in travelling and attending the hearing or a wish not to be "mixed up" in a case). (3) In view of the foregoing, the statement of the President that "an accused practitioner should call before the Council all material and relevant evidence in support of his case" (presumably this means his defence) "and if he fails to do so it is at his own peril," is nonsense, and is all the more disquieting in that it is, presumably, a considered statement, and emphasizes the need for the judicial activities of the Council to be placed in the hands of a trained lawyer, who could sit, if need be, with a medical assessor (similar to the procedure in Admiralty cases). Let the cobbler stick to his last.—I am, etc.,

South Shields.

TERENCE G. ROBINSON.

SIR,—The President of the G.M.C. says that an accused practitioner should call all material and relevant evidence in support of his case; if relevant evidence could be adduced and is not, the practitioner is responsible for an adverse view of the Council. But what if the necessary witnesses will not come? Neither the Council nor the doctor can compel them to. Until the Council is given power to subpoena witnesses, and obliged to do so on the motion of the respondent doctor, its disciplinary proceedings will continue to fall lamentably below any reasonable standard of justice.—I am, etc.,

London, S.W.19.

D. H. KITCHIN.

SIR,—May I express in your columns my support of, and gratitude to, Dr. R. V. Goodliffe, on his plain and decisive exposure of the G.M.C. President's complacent statement about the Council's recent gross injustice to a medical practitioner. That statement does mean: "We presume and hold you guilty until you satisfy us of your innocence."—I am, etc.,

Albert Dock Hospital.

H. M. HANSCHALL.

For two years the American-Soviet Medical Society has been publishing the *American Review of Soviet Medicine*. Arrangements have now been made for publication in this country. The first number of the British edition includes articles on: anaerobic infection of the brain; the role of vitamins in the pathogenesis and treatment of skin diseases; observations on the pathogenesis of hypertension; cyclodiathermy in secondary glaucoma; permeability of the haemato-encephalic barrier in massive arsenotherapy; immunization of diphtheria carriers; and "agonal states and clinical death." The publisher is Philip Firestein, 82, King Edward's Road, Hackney, E.9.

Obituary

PETER MCBRIDE, M.D., F.R.C.P.Ed.

Dr. Peter McBride, the veteran Scottish laryngologist who was for many years head of the ear and throat department of the Edinburgh Royal Infirmary, died on June 16 at St. Peter's Grove, York, where he made his home after spending some years in retirement at Harrogate.

Born on Aug. 16, 1854, son of James McBride, he went to school at Clifton College eight years after its foundation, and took his medical course at Edinburgh University, graduating M.B., C.M. in 1876; he was elected F.R.C.P.Ed., in 1880, and in the next year proceeded to the M.D., after attending clinics in Vienna to study diseases of the throat and ear. On his return to Edinburgh he was appointed to the staff of the Eye, Ear, and Throat Dispensary and began to lecture on diseases of the throat in the extra-mural School of Medicine. In 1883 he took charge of the new department for ear and throat diseases at the Royal Infirmary (where he had been resident physician) and held that position for twenty years, during the last five of which he was university lecturer on otology, rhinology, and laryngology. In recognition of his great service in building up the department he was made consulting surgeon in 1904.

Peter McBride was honoured by his fellow specialists far beyond the borders of Scotland. He had been president of the Laryngological Society of London, was twice president of the Section of Otology and Laryngology at Annual Meetings of the British Medical Association, and president of the Otological Section of the Royal Society of Medicine for two years; he had also been vice-president of the Otological Society of the United Kingdom. He was an honorary member of the Scottish Otological and Laryngological Society, corresponding member of the Berlin and the Vienna Laryngological Societies, and of the French Otological, Rhinological, and Laryngological Societies, also a corresponding Fellow of the American Laryngological Association. Three years after his retirement from active professional work he gave the Semon lecture in laryngology at the University of London in 1913.

In the course of a long life he wrote much. His *Guide to the Study of Ear Disease* came out in 1884, his *Diseases of the Throat, Nose, and Ear* reached a third edition in 1900, and he contributed many papers on affections of the ear, nose, and throat to medical journals; he had also translated Gottstein's *Diseases of the Larynx* in 1885. His miscellaneous writings included *Philosophy of Daily Life* (published under the initials "E.C.M."); *Psycho-Analysts Analysed* (1924); the *Riddle of Personality* (1926); the *Philosophy of Sport* (1932); and *Doctors and Patients: An Aid to Mutual Understanding* (1933). Keenly interested in outdoor and indoor sports and games Peter McBride loved a day with the hounds, and often hunted during his early years of retirement in Yorkshire. He had been a member of the B.M.A. continuously for 66 years.

H. G. EARLE, LL.D., M.B.

Dr. B. S. PLATT, Director of the Human Nutrition Research Unit, writes:

In the spring of 1941 Dr. Earle left his wife and family in England to return to Shanghai to his post as Director of the Henry Lester Institute of Medical Research to face the difficulties and dangers which he must have known were about to come to a head in the Far East. His action was in keeping with a high-minded sense of duty which characterized the care which he gave to the Institute he had nursed from its birth. In the same spirit he stayed on after his release from internment in Lunghwa Civil Assembly Centre at the end of the war with the Japanese. Although he had, by the end of the war, ceased to be Director of the Institute, he no doubt felt that he must do what he could to try to get it on its feet again. He must have suffered in mind during internment at the stupidity and waste of war, in spite of his naturally calm and philosophic outlook on life; for he loved peace and lived for the improvement of the lot of mankind. There can be little doubt that but for his sufferings undergone during the war he would have returned to a place of esteem and affection in medical circles in this country.

Dr. Earle had been adviser to the Henry Lester Trust since 1926. The Institute staff began to assemble in 1927 and grew in size and achievement till the outbreak of the Sino-Japanese war in 1937, when

its activities had to be considerably curtailed. Nevertheless, the annual reports from 1934 to 1940 are records of additions to knowledge over a wide field of medical research. His policy as Director was, to use his own words, "to stress the view that disease is a general biological problem and that all medical research should have a fundamental philosophical background if it is to be intelligently pursued." The loss of his wisdom and experience will be felt especially in China in the difficult period of rehabilitation ahead.

We regret to announce the sudden death on June 7 of Dr. JOHN DUKE STEWART, the well-known Dundee anaesthetist. He graduated M.A. of St. Andrews in 1915 and M.B., Ch.B. in 1921 and obtained the English D.A. in 1935. The following tribute comes from two colleagues: The tragic death of Dr. Duke Stewart has come as a shock to the people and medical profession of Dundee, where his services as anaesthetist were widely sought. For some years he had devoted himself entirely to the practice of anaesthesia and had recently been appointed lecturer on anaesthetics in the University of St. Andrews and promoted senior anaesthetist in Dundee Royal Infirmary. His keen interest in and knowledge of the subject, his patience and skill in the teaching of students, and his study of the problem of the individual patient pre-eminently fitted him for these responsible posts. Dr. Duke Stewart was particularly interested in the question of premedication and published a paper on this subject in the *British Journal of Anaesthesia* in 1939. He was a member of the B.M.A. and contributed articles to the *B.M.J.* Dr. Stewart was a Fellow of the International Anaesthetic Research Society and a member of the Scottish Society of Anaesthetists and of the Association of Anaesthetists of Great Britain and Ireland. Not only was his work known in the United Kingdom, but in 1941 he was elected a Fellow of the International College of Anaesthetists of U.S.A., and earlier had been invited to visit the United States to address the Society of Anaesthetists, but was prevented from accepting this honour by the outbreak of the war. The sudden death of one who gave such devoted service is a great loss and will be felt not only in Dundee but throughout the East of Scotland. Our deepest sympathy is offered to his widow and son.

News has been received of the death on June 14 at Berea, South Africa, after a long illness, of Dr. HENRY CURWEN, formerly principal medical officer of Zanzibar. Born in 1879, son of Robert Ewing Curwen of Frome, Somerset, he was educated at Trinity College, Glenalmond, and Edinburgh University, graduating M.B., Ch.B. in 1903 and taking the D.P.H. of Durham two years later. He was appointed senior medical officer for Zanzibar in 1907 and became P.M.O. to the Zanzibar Government and Protectorate in 1915. On his retirement in 1922 he was created C.B.E., and received from the Sultan the 4th Class of the Order of El Alich and the 2nd Class of the Order of the Brilliant Star of Zanzibar. Dr. Curwen represented his Branch at the Annual Meeting of the B.M.A. at Newcastle-upon-Tyne, and in later years held the post of medical superintendent of Kokstad Hospital, Griqualand East, Cape Colony.

Dr. VICTOR G. L. FIELDEN, who died recently, was consulting anaesthetist to the Royal Victoria Hospital, Belfast, and to the Ulster Hospital for Children and Women. He graduated in medicine at the old Royal University of Ireland in 1892 and obtained the M.D. with gold medal of Queen's University, Belfast. During the war of 1914-18 he held the temporary rank of captain, R.A.M.C., attached to the Queen's University O.T.C. He joined the B.M.A. in 1895 and was secretary of the Section of Pharmacology and Therapeutics at the Annual Meeting held in Belfast in 1909. Prof. P. T. Crymble writes: Victor Fielden was born in 1867 at Plymouth. His father was in the Royal Navy, and the son looked more like a naval officer than a doctor. He was a man of magnificent physique: over six feet, perfectly erect, he did most of his practice on a bicycle, and thought little of riding 25 miles to the seaside to see his family. Starting as a pharmaceutical chemist he followed the example of his chief, Sir William Whittla, and became a doctor. Almost immediately he started to specialize in anaesthetics, and for fifty years was our leading anaesthetist. Beginning with the Junker and bellows method he changed later to the Vernon Harcourt apparatus and continued to use this up to 1945. He proved that chloroform given in this way was an exceedingly safe method. In the University he taught practical pharmacy, and many stories are told in connexion with his classes. He formed a link with the past and could give a vivid description of operations performed under the carbolic spray. My own earliest recollection of Fielden was of seeing him simultaneously anaesthetizing and correcting proofs of Whittla's textbooks. Later he became my close personal friend

and did all my abdominal anaesthetics up to 1945. For many years he was a bellringer in St. Thomas's Church and gave long service to the Balmoral Reformatory. He had a very happy family life with a wife, a son, and five daughters.

We regret to announce the death of Dr. EDMUND ALBERT GOULDEN at Dymchurch, Kent, at the age of 76. He graduated in medicine at Manchester in 1893 and took the M.D. in 1905. The earlier part of his professional life was spent at Stockport, where he built up a large and busy practice. He served as captain in the R.A.M.C. in the 1914-18 war. He went through the hardships and horrors of the Gallipoli campaign and there developed cardiac trouble, which persisted to the end. At the close of the war Dr. Goulden went to Llandrindod Wells and practised as a spa physician until his retirement, owing to failing health, three years ago. He was an able physician and had a forceful and kindly personality. His death has been keenly felt by a wide circle of friends and patients. He had been a member of the B.M.A. since 1902.

Medico-Legal

ANOTHER CARBACHOL ACCIDENT

In June, 1942, a flight-sergeant of the R.A.F. died of an overdose of moryl, otherwise called doryl or carbachol, in the Cowley Road Hospital, Oxford. At the inquest¹ it appeared that the drug used had been packed in ampoules in crystalline form. Each ampoule contained a quantity of drug about 400 times the therapeutic dose. The instructions sent out with the ampoules said that the correct dose was 1/2 to 1 ampoule, but this referred to ampoules filled with solution and not with crystals. In 1944 the personal representatives obtained £2,000 damages from Messrs. Savory and Moore, the manufacturers, for negligence.² The manufacturers took steps soon after the accident to call in the blue packages containing moryl crystals, but a packet remained at the Croydon General Hospital, and the accident was substantially repeated on April 18 last. A married woman who had been admitted with cancer and a very rapid pulse was given the contents of an ampoule, 0.1 g. of the crystals, dissolved in sterile water. The correct dosage was 0.00025 g. She died in a few hours.

At the inquest Dr. H. G. McComas said that soon after the patient's admission he had instructed Dr. Maureen McNeill, the house-physician, to give one ampoule of moryl. Later she telephoned to him to say that the patient had died. He had examined the empty ampoule and the box from which it came, which had contained a blue paper saying that the dosage was 1/2 to 1 ampoule, to be repeated if necessary three or four times daily. Cross-examined, he said that he had seen the box before ordering the injection, and had seen that the ampoules contained crystals, but as he had never used the drug before, this fact did not strike him. It had never entered his head that the dosage on the box did not correspond with the contents of the ampoule. Dr. McNeill said that she also had not used moryl previously but had followed the directions of the blue paper in the box, which had corresponded with Dr. McComas's instructions. Mr. Samuel H. Stephenson, chief chemist of Messrs. Savory and Moore, said that the crystals, containing the drug in pure substance, were marketed for ionization. Tablets were prepared for administration by the mouth, and watery solution for injection. The firm's records showed that the hospital had ordered the box, containing 3 ampoules of 0.1 g. each, by telephone in December, 1940. Among other hospitals, Croydon General Hospital was asked by telephone to return the drug but had not done so, and the firm had presumed that it had been used. He agreed that the blue paper contained no word about the uses of the substance, and that the instruction did not apply to the contents of the ampoule. He thought, however, that members of the medical profession would have known this, for crystals could not be injected as they were. The jury returned an open verdict.

Medical journals have printed letters from the firm stating that it had called in the blue package containing moryl crystals and reissued the drug in an entirely new packet with a new colour scheme and literature. In case some hospital dispensaries may still have crystalline moryl with misleading directions, it is worth while to repeat the firm's request to examine their stores and return any moryl crystalline substance in the blue packet for free exchange.

Medical Notes in Parliament

HEALTH SERVICE BILL

In the resumed Committee stage on June 18 Mr. SOMERVILLE HASTINGS said that Clause 26 suggested that every general practitioner should be free to carry out inoculations against diphtheria. He felt that was undesirable on medical grounds. There was no objection to every medical practitioner undertaking vaccination, although the Government in times past designated certain practitioners as public vaccinators, but inoculation against diphtheria was a different story. Intradermal inoculations were not easy to carry out, nor were the Schick tests and the re-testing. Mr. LINSTEAD asked why compulsory vaccination was to be brought to an end by the repeal of the Vaccination Acts under subsection 5 of this Clause. Was this because of administrative difficulty or on medical grounds? Dr. BARNETT STROSS did not agree with Mr. Hastings. In hospitals, nurses and probationers were often expected to carry out hypodermic inoculations, and inoculation against diphtheria was usually a straightforward hypodermic injection.

Mr. BEVAN said there might be some forms of immunization or vaccination in which it was necessary to have special knowledge and it would be desirable for the local health authority to arrange for it to be carried out at clinics by a person with special experience. That was not ruled out by the Clause, but there were general forms of immunization and vaccination that the general practitioner could properly perform. The Bill provided for the general practitioner but did not exclude specialized arrangements. Compulsory vaccination had been dropped chiefly because large numbers of people were contracting out. At the same time, propaganda by the Ministry of Health urged people to have their children immunized against diphtheria and remarkable results were being achieved. In the controversy as to whether immunization or vaccination had established itself he must accept the specialist opinion that it had. The Clause was ordered to stand part of the Bill.

AMBULANCE SERVICES

On Clause 27 the Committee agreed, on the motion of Mr. KEY, to add words making it clear that the duty of a local authority to provide ambulance or similar transport existed only when there was a need for that transport; and that duty lay with the authority in whose area the need originated. Mr. BEVAN said the local health authority would have no regard to the origin of the patient but merely to his needs. The hospitals themselves would find it necessary to have a rudimentary ambulance service. A person who did not employ a doctor under the scheme but had a private doctor would get his ambulance free.

On the motion that the Clause stand part of the Bill Mrs. BRADDOCK said there would be duplication and delay in the methods proposed. The best way to deal with the ambulance service was to have a central service for the region, decentralized into areas, and alongside it a centralized bed bureau so that the regional organization would know what beds were vacant in every hospital. Mr. MESSER said that unless the ambulance service came under the same authority which was administering the hospitals there would be delay, if not confusion. Within the management committee area of a hospital there ought to be authority vested in the hospital to ensure that it would immediately get an ambulance. The hospital workers had expressed a hope that there would be a national ambulance service.

Mr. WILLINK hoped Mr. Bevan would not yield to pressure to make this a regional service. It should be normally a function for the county or county borough but with liberty to the Minister, as in the Bill, to make a larger joint unit for the purpose of an ambulance service. Dr. MORGAN supported the contention of Mrs. Braddock. He said that ambulance workers were trying to get an institute of ambulance workers with a definite training and curriculum for study. Employees of voluntary associations were unlikely to be really trained ambulance personnel.

Mr. BEVAN said all the arguments advanced by Mrs. Braddock were arguments for the merits of the local health authority ambulance service. The ambulance service was not a hospital service only—a local health authority was responsible for identifying cases to be taken to mental homes. The regional authorities were very far away from the administrative front and, after the regional plan had been made and the specialists had been appointed, the regional board would break down administratively into the hospital management committees. To add to that board a day-to-day administrative function seemed to him to be unrealistic. The local health authorities would

take exception to being under the supervision of a non-elected authority. The Clause as amended was ordered to stand part of the Bill.

PREVENTION OF ILLNESS

Mr. PIRATIN moved to amend in Clause 28 the provision respecting arrangements made by a local authority for prevention of illness, care of persons suffering from illness, or after-care of such persons by deleting the condition that "no such arrangements shall provide for the payment of money to such persons." He referred particularly to the work done by tuberculosis after-care committees and other organizations of a similar nature. He said that many a mayor's fund contributed to such people who were given lump sums of money. At present, under Memorandum 266.T., a regulation gave a fair sum to certain tuberculosis cases for after-care. The Bill would end this and there was nothing to replace it. Mr. MESSEY said that Parliament was going to repeal the 1921 Act so that all the tuberculosis work would be merged with the general health services; unless provision was made for the hospital authority to follow up its cases there was a danger that the service would be retrogressive.

Mr. BEVAN said the payment of money was a function of the Ministry of National Insurance. Certain categories of assistance were provided under the health scheme, but there would be a number of categories for which a new Bill would be necessary. It would deal with the winding-up of the poor-law system. The tuberculosis scheme had done extremely good work but had the cruel defect that when a person was found to be incurable the allowance stopped. Legislation would be required to alter that.

Mr. PIRATIN withdrew his amendment and moved another to delete subsection 2 of Clause 28, which authorized a local health authority to recover charges from persons availing themselves of the services provided under the Clause. Mr. BEVAN resisted the amendment. It would be impracticable to ensure that anyone who needed someone in attendance should have that service free.

The amendment was negatived, and on the question that the Clause as amended stand part of the Bill, Mr. REES asked for guidance on the interpretation of the words "the care of persons suffering from illness." Mr. LINSTED asked for some explanation of the arrangements to be made for prevention of illness. In Clause 28 the Committee had one of the few provisions in the Bill aimed at prevention as distinct from treatment and cure. Was the Minister asking for a large extension of educational health services at the expense of the local authority? Mr. WILLINK said the Minister had had representations from the National Council for Mental Health, which was concerned in providing for the care of those who were ill though they might not fall within the categories of illness or mental defect. There were serious cases of epilepsy and of neurosis. Did the Minister feel that he was able to make provision for helping such persons.

Mr. BEVAN said certain persons would be unable to follow some occupations but could follow others. The local authority would be empowered to establish and supervise special industrial premises in which such people could carry out their employment. Colonies could be established for persons suffering from certain disabilities. It was not, however, intended to apply this extensively. The Clause as amended was ordered to stand part of the Bill, as also was, with a minor amendment, Clause 29 (Domestic Help).

APPOINTED DAY

Clause 30 was also ordered to stand part of the Bill. Mr. BEVAN remarked that the administrative work to be done after Parliament passed the Bill would be enormous, and considerable time would elapse before the whole of the scheme was in operation. Even after that the full service would depend upon its being properly manned. The country was short of doctors, specialists, dentists, and health centres. He inclined to the view that until they could build new health centres they should adapt old buildings. It was intended that the Bill should come into operation on April 1, 1948. He did not think it would be possible to introduce it before that. It must be synchronized so far as possible with the National Health provisions. It would come into operation in different stages. He hoped to appoint the regional boards quickly; the local authorities would become authorities under the Bill as soon as it was passed. The Clause was ordered to stand part of the Bill.

LOCAL MEDICAL COMMITTEES

The Committee proceeded to examination of part 4 of the Bill which deals with general medical and dental services, pharmaceutical services, and supplementary ophthalmic services. On Clause 31 Mr. WILLINK drew attention to subsection 3 providing that the Minister may by order vary the constitution of

an executive council. He said the set-up of the new body with which doctors were to be in contact had given general satisfaction but the Minister was asking for a blank cheque of power to vary it. Mr. BEVAN said variation took place only after consultation with the local executive council concerned. The Minister did not act arbitrarily. Some of the functions of an executive council must be over a wider area, for example, in price-fixing for chemists' prescriptions. The Clause was ordered to stand part of the Bill.

On Clause 32 Mr. WILLINK moved that the term in the Bill the "Medical Practitioner Committee" should instead be termed the "Local Medical Committee." He pointed out that this would avoid confusion between the two bodies which the Bill termed "Medical Practices Committee" and "Medical Practitioner Committee." The amendment was agreed to and the Clause as amended was ordered to stand part of the Bill.

THE SPENS COMMITTEE REPORT

Mr. RICHARD LAW moved to add a new subsection to Clause 33 to provide that where the Minister on the advice on the Central Council was satisfied that by reason of the scattered population, or other special circumstances, it would not be practicable to give the inhabitants of an area, or a considerable proportion of them, satisfactory medical attention if the remuneration of the medical practitioners were by way only of capitation fees, they should be paid in addition such annual salary as might be prescribed. There was no word in the Bill stating what the conditions of the State medical service would be. If authoritative reports were to be believed, the Minister told the medical profession before Second Reading that the payment of general practitioners would be largely by a salary; yet he told the House on Second Reading that it would be substantially by capitation fee. Mr. Law hoped the Minister still had an open mind in this matter and that now he had received the Spens Committee Report he would feel able to give his intentions legislative effect in this Bill.

Mr. Law drew from the Spens Report the conclusion that to avoid a deterioration in the general practitioner service the monetary reward would have to be greater than in the past. He also inferred that there should be elbow-room within whatever scale of payment might be decided upon so that the skilled, efficient, and conscientious doctor might expect a greater financial reward, and so that the doctor who had exceptional skill in dealing with his family patients could expect a very high salary indeed. He took it that the Minister and the Committee would agree with the objectives that the Spens Committee had outlined. How could these objectives be met unless the Minister abandoned his idea of payment by basic salary and went back to a capitation fee alone, except in the under-doctored areas? He did not see how the Minister could make the principles of the Spens Report effective by a varying salary scale. Nor what standard Mr. Bevan could lay down which could justify one doctor receiving a higher salary than another. The Spens Committee itself decided that exceptional medical degrees would be an ineffective standard for exceptional financial rewards. It seemed to him that the only way to get round the difficulty of deciding how to give varying degrees of reward in a comprehensive State medical service was to allow the patient himself to decide. Where a doctor by his skill, sympathy, and devotion attracted patients he should be rewarded. He hoped Mr. Bevan would abandon his idea of a basic salary and go back to the principle of a capitation fee which would vary with the number of patients a doctor had on his list.

THE MINISTER'S VIEWS ON REMUNERATION

Mr. BEVAN said it was not only unprecedented but undesirable to put the method of remuneration in a Bill. That was not done in the original Health Insurance Act and had not been in any of the Acts since then. Parliament could have no more unpleasant duty than to argue about wages and conditions. That was much better done by regulation, and he believed the doctors would prefer it so. He did not think the Central Council was the appropriate body for giving advice on this matter. He was unable that day to indicate the attitude of the Government towards the Spens Committee's Report. He would like to see the principles of that Report expressed in a definite formula within the framework of the Bill. At the moment they were in the form of abstract principles, but the committee had provided a valuable document and he was grateful to its chairman and members.

Mr. Bevan said he was firmly convinced it was necessary to have an element of basic salary in the doctors' remuneration. A young doctor must be able to start work with his livelihood assured. At present young doctors sometimes spent a substantial number of years before they could win anything like a reasonable livelihood. The doctor was fairly old before he started, and either he could not get a family or could not keep

one under the conditions in which some doctors had to live. The arguments for a basic salary were overwhelming. The medical profession contained a number of dedicated persons, but he had not been able to see in it, in general, any more idealistic attitude towards remuneration than existed in any other profession. Some element of punishment and of reward was necessary. For that reason he had come down on the side of capitation as part of the pay. If the system was full salary, then one had to allocate patients among the doctors and doctors among the patients. That would result in an unhealthy relationship between patient and doctor. Therefore the Ministry found it necessary to have capitation. When the regulations were drawn up, he thought there would have to be a ceiling to the capitation and other modifications might be necessary. These would be subjects for negotiation with representatives of the profession. He was in consultation with the profession on these matters, and he preferred that the consultations should reach a more advanced stage before he expressed any definite opinion. The Government was clear where it stood. A uniform capitation and a variation of the basic salary was far better than a variation of capitation. It would give an opportunity for providing a principle by which the Ministry could attract doctors into under-doctored areas. Parliament would have an opportunity later of discussing the regulations when they were made.

Mr. REID said that to leave a blank cheque in the Bill on a matter of this importance was wrong. The Opposition proposed that there should be put in the Bill a clear direction in principle as to the method by which the remuneration was to be made up. Wherever it was found that there was a need to attract doctors to an especially difficult or unpopular area then the right way to attract them was to give a salary in addition to the capitation fee. If the area was very difficult or unpopular then it might require £500. The determination of the area, and of the amount necessary, was an administrative matter which might change from year to year and which no sensible person would put into the Bill. The Minister had provided no argument for giving a salary to a doctor with the same experience who was practising in an over-doctored, or average well-doctored area. One must assume that the only argument for giving him a salary was the doctrinaire one that all doctors should be the servants of the State and not of their patients. With regard to the young doctor, in most cases the right way for him to start was as an assistant, and the Bill left Mr. Reid in doubt how the position of assistant was to be preserved when the Bill came into operation. He agreed that Mr. Bevan was right in contending that the words "the advice of the Central Council" should be taken out of the amendment proposed by Mr. Law. There was a proposal in the White Paper that the capitation fee was to diminish in scale as the total number of patients rose. To increase the size of the panel did not alter the proportion of the people coming to the surgery. Therefore the payment must be per patient. Why should the good doctor be paid on the average less per patient than the bad doctor? In a particular area they generally found that the doctor with the large practice was the doctor who inspired most confidence.

Resuming on June 19 the discussion of the amendment proposed by Mr. Law, Mr. LINSTED said the facts did not justify the contention advanced by Mr. Bevan that it was necessary to provide salaries to help the young doctor to establish himself immediately after qualification. Nothing was easier than for the young medical practitioner to get financial support to establish himself in practice. He was opposed to the proposal to pay by salary but could not see that payment by salary or by capitation fee would make much difference for many years to come. There was going to be a shortage of doctors and however remuneration was made up all doctors would have all the patients they were allowed to take. The real question was how far the Committee wished the doctor to be an independent practitioner. The Opposition felt that when a salary element was introduced the doctor was made the servant of the State through the regional board.

METHOD OF PAYMENT

Mr. SOMERVILLE HASTINGS hoped the Minister would not fix a hard-and-fast rule on remuneration and salaries. Payment partly by salary and partly by capitation fee would be most popular among doctors. According to the questionnaire issued about two years ago by the British Medical Association, the majority of those who had filled in the forms decided that that was the most satisfactory method. Mr. Hastings suggested that very soon the majority of doctors would wish to be paid by salary. The advantage of capitation was that by it a doctor built up goodwill. In the future goodwill would not be saleable and that advantage would disappear. It would not always be easy for a young man to start in practice. The young man starting in practice with a small salary and a free list would have to take those people who had not expressed a choice or

could not be accommodated on the list of the doctor they had chosen. In addition the young man would have to try to attract as many patients as he could from other people's lists—not an elevating procedure. He would have plenty of time to contemplate how much better off he would be if he were paid a reasonable salary. Capitation gave the patient too much power over the doctor.

Sir HUGH LUCAS-TOOTH remarked that Mr. Bevan had said it was essential to have an element of reward and punishment. Did he mean that the basic salary should be used for some disciplinary purpose? Mr. BEVAN said obviously the reward and punishment related to the capitation grant because if a doctor was not industrious the patients would transfer to another doctor.

Dr. STEPHEN TAYLOR said the Spens Report made him feel there was a lot to be said for having a capitation fee element. Doctors after reaching a certain age deliberately cut down the work which they did. Provided patients could recognize a good doctor there was much to be said for their playing a part in deciding how much a doctor should get. In some parts of England doctors were divided into classes—the non-examining and the examining doctors. A doctor with higher qualifications had a case for having slightly more income than a doctor who did not take those qualifications. There was a case for giving doctors a bit more on their basic salaries as they got older. There was a case for the cash incentive for doctors to take a three-months refresher course after every ten years. Mr. WILLINK said a general service organized by the State could not be a service in which promotion was obtained from one grade to another. It was clear from what Mr. Bevan had said that the incentive to gather in people for whom the general practitioner must care was going to be reduced by every pound the basic salary was increased.

NEED FOR A BASIC SALARY

Mr. BEVAN said that members of the Opposition had been misled by uninstructed propaganda issued when the Bill was first published. All the references to State service, bureaucratic control of medical services, and to the virtue of unlimited competition between doctors had no relation to the proposition before the Committee. There was no need for him to repeat the arguments in favour of an elementary basic salary. At the same time he had accepted the proposition that a full salaried service was not reasonable and in existing circumstances would not operate to the best advantage of the community. Therefore he had reached a compromise between the two principles, introducing the element of security for the individual and the element of competition to refresh the service. Dr. Taylor had suggested that it was not attractive to have a diminishing capitation rate when reaching the higher lists. Mr. Bevan had proposed that to try to destroy the worst features of the panel system. The unlimited panel system now had for Conservatives almost mystic virtues. In the passage of years it had acquired a nimbus, but in 1911 it had horns. Very great evils were established in the building up of a panel system, brought about by the competition between the doctors themselves, and this led to a very undesirable situation. He had an open mind on the desirability of declining the capitation rate. It was not a matter of fundamental principle. It would have to be examined in the light of discussions with the profession. He was not impressed by what doctors said in their questionnaire. The amendment proposed by Mr. Law was defeated by 25 to 12.

ASSISTANTS IN GENERAL PRACTICE

Col. STODDARD-SCOTT moved to add a proviso that nothing in the Act and no regulation should interfere with the right of a general practitioner who undertook to provide general medical services to employ and pay under contract with himself an assistant. It was advantageous for a young man qualifying in medicine to act as an assistant to a capable principal. Mr. BEVAN thought this was a desirable way of introducing a doctor to general practice. But the Government could not give general practitioners an unrestricted right to take on as many assistants as they liked, because that would interfere with the proper distribution of doctors. It was intended that there should be no restriction on the right of general practitioners to have assistants in areas where the Executive Council agreed that these could be employed because the area was not over-doctored. Assistants would not be on the list but would be registered doctors.

Mr. HASTINGS asked whether the assistant would be bound by agreement with his principal not to start practice on his own in the same area. Mr. BEVAN replied that it would not be reasonable if a doctor took on an assistant who remained with him for some time for that assistant to go on the list for that particular area. He had already had discussions with the profession on what area of restriction should be imposed. The amendment was withdrawn.

On the motion that Clause 33 stand part of the Bill Col. STODDARD-SCOTT said subsection 2 (d) of the Clause dealt with certification and suggested that this would be decided by regulation. These regulations would refer only to doctors inside the service. He desired an assurance that doctors outside the scheme would be able to issue certificates which would be accepted. Mr. BEVAN said what certificates were accepted was a matter for the Minister of National Insurance. He himself thought that the certificate of doctors, whether in the public service or outside, stood on an equal footing. Clause 33 was ordered to stand part of the Bill.

DISTRIBUTION OF DOCTORS

Mr. WILLINK, moving an amendment which was rejected, said that the distribution of practitioners would improve automatically on the introduction of this Bill without the measures proposed in Clause 34. The Bill would enable 100% of the population to be safe patients from the financial point of view. The moment Mr. Bevan controlled distribution he automatically affected the value of goodwill. Some first-class doctors would shrink from the controls which had to be introduced into a service of this kind. It was in the public interest for such a doctor to be able to say that the bulk of his work was to be in private practice but that he would like to have a panel of 500 or something of that kind.

Mr. BEVAN said that Mr. Willink's point of view involved continuation of the sale and purchase of practices; it also involved a doctor choosing his own successor. Having decided as a first principle to abolish the sale and purchase of practices Parliament had then to determine the principle of succession. To that the machinery under Clause 34 was the necessary corollary. It was accepted by the medical profession that there was bad distribution of medical services. Therefore the procedure involved a negative control. In the future the young doctor would receive information from a central pool as to what areas he could go to at once and the areas where he would not be acceptable in the public service. He would know within a day and would not have to advertise or ask his friends. When there was a vacancy the local Executive Council would notify the local doctors' committee, so Parliament got the doctors themselves influencing the appointment of their new colleagues, the local executive appointing, and the central committee confirming the appointment.

Captain BAIRD asked what happened when there was a vacancy in an area for one doctor and five applied. Mr. BEVAN said in that case the doctors in the area would be invited to suggest a doctor who in turn would be suggested to the Executive Council. With the permission of the medical practices committee a contract would be entered into. Dr. TAYLOR hoped that every vacancy would be advertised in the medical journals so as to give the maximum field of choice. Practices should not be inherited.

Referring to other inquiries Mr. BEVAN said that all these things depended on sensible administration and could not be put into the Bill. There could be an appeal to the medical practices committee in the very rare circumstances in which irregular things had been done and undue influence exercised.

CONSULTATION WITH LOCAL MEDICAL COMMITTEE

On June 20 Mr. WILLINK moved an amendment to Clause 34. He proposed that applications by doctors to be included in the list of practitioners undertaking to provide general medical services if made in the prescribed manner to an executive council should be referred by that council to the local medical committee and that the recommendations made by that committee and the decision of the council thereon should be submitted to the medical practices committee. During the second reading of the debate he had formed the impression that Mr. Bevan very largely agreed that the choice of individual practitioners was not an appropriate function for one central committee. Mr. Bevan had said in that debate that in fact the executive would appoint the practitioners and they would be referred to the medical practices committee solely on the question whether that particular area was under-doctored or over-doctored. He noted that Mr. Bevan had put down an amendment to provide that before selecting any persons under this clause the medical practices committee should consult the executive council concerned and that council should, if a local medical committee had been formed for the area of the council, consult that committee before expressing its views on the persons to be selected.

Mr. BEVAN said there was not much between him and Mr. Willink. He thought the amendments he had put down satisfied the necessities of the case. The only circumstances in which the medical practices committee would be likely to question the appointment would be where some improper action had taken place. In order that the committee might have

authority to move it was necessary that, formally, they would make the appointment. He did not mean that the executive council should send forward three or four names to the medical practices committee. The local medical committee would say to the medical practices committee: "We propose to appoint Mr. Blank." The medical practices committee would never know who Mr. Blank was unless somebody said to that committee: "Something improper has happened down here." Did anybody imagine that a busy central committee was going to worry itself about the whole of these individual appointments? If the committee did not concern itself when something wrong had happened the Minister must do so, and the Government did not wish to drag the Minister into it. The executive council would proceed to do the job in the normal way, consult the local doctors, make the appointment, and send the name in to the medical practices committee, who would then authorize the appointment. Supposing a name were sent in and representations came from an authoritative quarter that there had been something improper in the selection, the medical practices committee would make an inquiry and say: "We are sorry, but we cannot confirm this appointment. Try again and make another appointment."

Mr. Willink's amendment was by leave withdrawn, and the Committee accepted Mr. Bevan's amendment.

"Before selecting any persons under this sub-section, the Medical Practices Committee shall consult the Executive Council concerned and that Council shall if a Local Medical Committee has been formed for the area of that Council and recognized under the Act but one foregoing Section consult that committee before expressing their views on the persons concerned."

FAMILY PRACTICES

Mr. LINSTAD moved, and later withdrew, an additional subsection to provide that the medical practices committee, medical practitioner committee, and executive council in exercising any power or determining any appeal under Clause 34 should have regard to a desire expressed by members of a family to work together or by a medical practitioner to succeed to the practice of his father or other near relative. He also wished to provide that these bodies should have regard to the views of the remaining members of a partnership before selecting a candidate to fill the vacancy. Mr. BEVAN said he did not think the committee should give a special statutory value to family relationships. It was often desirable that there should not be too much interbreeding in local areas and that there should be more infiltration from outside. He agreed that tradition would inevitably have its influence on the selection, but he did not wish to give directions to local executive councils about this; but it was just the sort of thing they ought to be free to do. The Minister ought not to tell local executive councils what sort of grounds they should consider in making an appointment.

On the motion that Clause 34 stand part of the Bill Sir HUGH LUCAS-TOOTH inquired the meaning of "already adequate" in the proviso that the medical practices committee could refuse an application to practise on the grounds that the number of doctors undertaking general medical services in the area or part of the area was already adequate. Mr. BEVAN said there could be no absolute definition of adequacy. Adequacy related first to the general supply of doctors for the country as a whole, secondly to the way that supply had distributed itself over the country, and, after these considerations had been borne in mind, to the special requirements of the areas under discussion. In some areas more doctors were needed because the average age of the population was higher. The Bill provided that the decision on the needs of an area would be made by the medical practices committee on which the majority would be doctors with experience of what was required. The Clause as amended was approved by 24 to 12.

PROHIBITION OF SALE OF PRACTICES

On Clause 25 Mr. WILLINK moved to add a proviso that if one or more members of a partnership were included in a list of practitioners undertaking to provide general medical service but one or more other members of that partnership were not included in such a list, nothing in the Act would apply to any sale of goodwill by a member of the partnership not included in that list. In English law goodwill was the asset of the partnership and not of the individual partners. What was to happen between now and the appointed day to partnerships where only one or some of the partners engaged in panel practice? This Clause would involve the dissolution of hundreds of partnerships all over the country before the appointed day. The Minister desired group practice, but the prohibition in the Clause would strike a grievous blow at co-operative work between medical men.

Mr. HENRY STRAUSS said he suspected that when drafting subsection 1 of the Clause the draftsmen had not partnerships

in mind. The Clause was so obscure that any doctor or any doctor's representative after the doctor's death or any doctor in an existing partnership who consulted a lawyer, assuming this Clause went through in its present form or even as amended by the amendments proposed by Mr. Willink, could only be advised to wind up the partnership and dissolve it before the appointed day.

Mr. BEVAN said nothing obscure in the Clause. He said that hitherto the Clause had been attacked on the ground that it was terrorizing and dealt comprehensively with so many different varieties of circumstances where persons might try to secure payment for goodwill even after compensation had taken place for loss of goodwill. Most of the terror had been taken out, although the protection for the Exchequer still remained. He was advised that the amendment proposed by Mr. Willink was unnecessary. But if the language of the Clause would have the effect of causing partnerships to be universally dissolved then the Clause would have to be amended. He promised to look into the question. Mr. Willink withdrew his amendment.

TRIAL BY JURY

In subsection 2, dealing with penalties for the new offence of unlawfully selling or buying a goodwill or part of a goodwill, Mr. WILLINK moved an amendment to provide that on summary conviction an offender should be liable to a fine not exceeding £100 and that the larger penalties proposed in the Bill should be applicable only in cases of conviction on indictment. He said that in another Bill the Government recently accepted the argument that it was inappropriate to give such powers to courts of summary jurisdiction. The Bill would give rise to questions of subtlety and difficulty. There were questions of allocation of the consideration given for a house and how far payment was because it was a nice house and how far because it had a surgery. There was a splitting of a series of transactions with the apportioning of consideration for the practice as against other elements in the contract. There was also the question whether money given by a son to his father was given in contemplation of his succeeding his father in the practice. Clearly more serious cases ought to go for trial by jury.

Mr. BEVAN agreed that where the higher penalties were involved there was a good case for the matter being tried by a court with a jury. He thought Mr. Willink might leave him to move an amendment at a subsequent stage. He did not wish the penalties to be too light. Parliament had met many examples of persons who went on violating the law because they made profit by that violation even after paying the penalties. The Government did not wish that to be done. These cases would occur only on the part of doctors who had entirely misrepresented to the medical practices committee what they had done or who had neglected to protect themselves by getting a certificate from the medical practices committee or who were persons obviously with felonious intent.

SALE OF A DOCTOR'S HOUSE

Mr. WILLINK next moved to omit subsection 4 dealing with the sale, letting, or other disposition of premises previously used by a doctor for the purposes of his practice. Mr. Willink said that although ingenious persons might work a sale of goodwill into the sale of the house the Opposition felt that this subsection was so unsatisfactory that its omission must be moved. It set up criteria which seemed to be unworkable, and it also covered cases which Parliament never intended to cover. The danger was not of people being unfairly convicted but of professional men being unfairly brought before the courts and subjected to embarrassment and expense. The criminal law should be clearly expressed. Mr. STRAUSS said part of the mischief of the subsection as it stood was that it created a criminal offence not dependent on any guilty intention.

Mr. BEVAN agreed that Parliament ought not to pass bad laws on the assumption that there was a good public prosecutor. He had considered this matter carefully because it did create a number of criminal offences, and the Government did not want to torment innocent people. At the same time the Exchequer had made a generous provision for the payment of £66,000,000 to the doctors in compensation for the loss of goodwill, which was far more than the medical profession ever expected. The State during many years had permitted a most pernicious system to grow up, but the doctors were as much victims of that system as they were beneficiaries from it; and when the State stepped in to destroy that system the Government had said that compensation must be paid. These practices had existed for a considerable time and were extremely involved, and he felt that some doctors who had not received compensation might want some payment for their goodwill which had already been bought by the State. The Government had to consider all the various ways in which doctors

obtained pecuniary advantage for their goodwill. One of the most valuable was the doctor's house. He was advised that it would be perfectly proper to give more for a doctor's house because of the physical structure of the house. If there was a surgery, if there was apparatus, if there was a special structural arrangement it would be proper to pay more for the house because of those conveniences. What the subsection did was to prevent the seller from obtaining a sum of money in respect of the fact that goodwill attached to the house.

Mr. STRAUSS asked the Committee to assume that the house had a special value because it had always been a doctor's house and that therefore whoever went to live in it attracted a certain amount of goodwill. The executors of the late doctor might not desire that extra value, but if the house were put up for auction the price would be influenced by the fact that it had been a doctor's house. If the house had been sold for more than if it had never been a doctor's house an offence would have been committed, though there was no guilty intention. Did Mr. BEVAN intend that it should be impossible for the widow to sell that house by auction without risking a criminal prosecution? Mr. BEVAN said he could not accept that. If goodwill had been made illegal from April 1, 1948, that would entirely change the value of doctors' houses in respect of the goodwill attaching to them. The Committee rejected Mr. Willink's proposal by 21 to 10.

In subsection 5 of Clause 34 dealing with valuable considerations given by or to partners in pursuance of any partnership agreement between doctors Mr. WILLINK moved to insert the words "made after the passage of this Act." He asked who could say what ought to be reckoned the appropriate consideration in 1947 on the basis of the facts of 1933 or 1943? Under the Bill if the shares of the partnership were inappropriate to the energy, skill, and success of the partners then there would be a criminal offence. The only way in which the Government proposal could be workable was by making it affect partnership agreements entered into after the Act. What was to happen supposing that there had been an agreement for the acquisition for the share of a partnership, the payments to be made in five instalments payable at intervals of two years, two instalments having been paid and three remaining to be paid? The payment of the third, fourth, and fifth instalments would be a crime in respect of something which had already been acquired. His amendment was intended to get rid of all pre-Act partnerships so far as this crime was concerned.

Mr. BEVAN said people ought not to be able to obtain money under false pretences. It was not the case that where a sale had taken place before the appointed day instalments due to be paid afterwards would have to cease because if they were paid that would be a crime. He was advised that under subsection 1 the legal sale would have taken place before, and therefore it was not indictable. It would be foolish to make an offence prospective. If the language of the clause bore that interpretation then it must be altered, but he was informed that it did not. There was no real difficulty in deciding the services rendered by one partner to another. A certificate obtained for these transactions from the medical practices committee was ample protection. A method of protecting the doctor from the consequences of ambiguity had been created.

Mr. HOPKIN MORRIS asked the Minister to reconsider subsections 1 and 5, and Mr. STRAUSS appealed to him to consult the Law Officers before the next sitting. He said the Minister was running a risk that the medical practices committee would be approached with questions about every existing partnership. The amendment was defeated by 21 to 7, and the Committee agreed to an amendment proposed by Mr. BEVAN to insert the words "having regard to the circumstances at a time when agreement was made." The Committee then adjourned.

Grants for Teaching Hospitals

In respect of the academic year 1945-6 an interim distribution of grants for teaching hospitals has been made thus: Universities in England and Wales £166,169, University of Aberdeen £9,046, University of Edinburgh £24,048, University of Glasgow £22,678, University of St. Andrews £8,027. The University Grants Committee will make recommendations for a further final distribution of the grant available for 1945-6.

Artificial Limbs.—Mr. WILFRED PALING on June 20 told Sir Ian Fraser that during the last six months deliveries of artificial limbs exceeded orders placed. He had no reason to think that this position would not be maintained. He anticipated that the time would soon arrive when the supply and repair of artificial limbs would be effected more expeditiously.

Notes in Brief

Mr. William Leonard stated on June 20 that the expressions "registered medical practitioner" and "duly qualified medical practitioner" were synonymous by virtue of Section 34 of the Medical Act, 1858. Current drafting practice favoured the former.

Universities and Colleges

UNIVERSITY OF OXFORD

I. V. Potunin, B.M., of Queen's College has been elected to the Schorstein Research Fellowship in Medical Science for one year from October 1.

UNIVERSITY OF GLASGOW

At a graduation ceremony on June 19 the honorary degree of LL.D. was conferred on Archibald Wilson Harrington, M.D., formerly Muirhead Professor of Medicine in the University, and on Sir Edward Mellanby, K.C.B., M.D., F.R.S., Secretary of the Medical Research Council.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The Prime Minister, who is a Hunterian Trustee, dined with the members of the Council, at the College, on June 5. He saw the damage which had been caused to the buildings by enemy action, and inspected the plans for rebuilding. Others present were:

The Earl of Athlone (Hunterian Trustee), Sir Alfred Webb-Johnson, Bt. (President), Sir William Collins (Hunterian Trustee), Sir Hugh Lett, Bt., Sir Max Page (Vice President), Sir Henrice Ogilvie (Vice President), Mr. A. F. Burgess, Mr. Victor Bonney, Sir James Walton, Mr. H. S. Souttar, Mr. Cecil P. G. Wakeley, Mr. L. E. C. Norbury, Mr. V. Zachary Cope, Prof. Hugh Cairns, Mr. P. H. Mitchiner, Mr. A. Tudor Edwards, Surg. Capt. Lambert Rogers, Mr. Geoffrey Keyes, Mr. R. J. McNeill Love, Dr. H. Guy Dain, Mr. G. F. Stables, Mr. V. E. Neuge, Dr. A. D. Marston, Mr. George Black, Prof. F. Wood-Jones, Prof. R. A. Willis, Prof. A. J. E. Cave, and Mr. W. F. Davis (assistant secretary).

ENGLISH CONJOINT BOARD

Diploma in Industrial Health

The Examining Board in England set up by the Royal College of Physicians of London and the Royal College of Surgeons has issued regulations for obtaining the Diploma in Industrial Health (D.I.H., R.C.P.Lond.&R.C.S.Eng.). It may be granted to those who possess a qualification registrable in the British Medical Register and to graduates in medicine and surgery of those universities and medical colleges recognized by the Examining Board in England for the purpose, who comply with the regulations. Candidates for the diploma are required to follow the curriculum of study, to pass the examinations, and to pay the prescribed fees, but exemption from Part I may be granted to candidates who hold a recognized Certificate in Public Health. Copies of the regulations may be had from the secretary, Examination Hall, 8-11 Queen Square, London, W.C.1.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In England and Wales infectious diseases were less prevalent. There were decreases in whooping-cough 310, scarlet fever 83, acute pneumonia 50, measles 35.

The decline in whooping-cough was fairly widespread, and the chief falls were Lancashire 56, Warwickshire 36, Carmarthenshire 36, Surrey 34, London 31, Essex 29. The only change of any size in the local returns of diphtheria was a fall of 27 in London. A small decrease in scarlet fever was fairly general, and the only large fall was Middlesex 33. Considerable variations occurred in the trend of measles; the largest rises were London 106, Yorkshire West Riding 89, Surrey 52, and notable decreases were Middlesex 82, Lancashire 78, Durham 46, Warwickshire 45.

Notifications of dysentery declined by 14. The largest returns were Lancashire 40, London 17, Warwickshire 12, Dorsetshire 11.

In Scotland the only rise recorded was measles 12; the falls included acute primary pneumonia 67, scarlet fever 12, whooping-cough 11, dysentery 10. The decline in dysentery was due to the experience of the western area, where there were only 7 cases, compared to 24 in the preceding week.

In Eire also a general fall in prevalence was recorded; the only rise was whooping-cough 15. Only 27 cases of diphtheria were notified, spread over 16 registration areas.

In Northern Ireland an increase was reported for whooping-cough 28, diphtheria 7, measles 7, while scarlet fever declined by 6. All the cases of whooping-cough were notified in Belfast C.B.

Week Ending June 15.

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 866, whooping-cough 1,625, diphtheria 262, measles 4,415, acute pneumonia 505, cerebrospinal fever 44, dysentery 146, poliomyelitis 12, small-pox 2, paratyphoid 4, typhoid 7.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 8.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, as of Deaths recorded up to each infectious disease, are for: (a) The 125 great towns in England and Wales (London included), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

Medical News

A general meeting of the Medical Society for the Study of Venereal Diseases will be held at 11, Chandos Street, W., to-day, Saturday, June 29, at 2.30 p.m., when there will be a discussion on "The Treatment of the Infected Female by Penicillin."

A meeting of the Royal Sanitary Institute will be held at Stoke-on-Trent Town Hall on Saturday, July 6, at 2.15 p.m., when Dr. A. Meiklejohn will read a paper on "Silicosis."

The X-ray Analysis Group of the Institute of Physics announces that its 1946 Conference will take place at the Royal Institution, 19, Albemarle Street, London, W., on July 9, 10, and 11 next, and is open to all without charge. It is hoped that several distinguished foreign scientists will participate in the proceedings. Further information will shortly be available from the honorary secretary, Mr. F. A. Bannister, F.Inst.P., Department of Mineralogy, British Museum (Natural History), Cromwell Road, S.W.7.

The County Borough Group of the Society of Medical Officers of Health have arranged to hold its annual meeting and week-end conference from July 19 to 22 at the School of Domestic Economy, Eastbourne, under the presidency of Dr. R. H. H. Jolly. The programme includes "The Care of Homeless Children," by Dr. J. Fenton, M.O.H., Eastbourne; "The Peckham Pioneer Health Centre," by Dr. G. Scott Williamson; "The New National Health Service," by Dr. J. F. Galloway, M.O.H. Doncaster; "Medical Administration as a Career," by Prof. J. M. Mackintosh. The hon. secretary of the Group is Dr. J. Greenwood Wilson, City Hall, Cardiff.

The annual dinner of the Royal Medico-Psychological Association will be held at the Royal College of Physicians, 9, Queen Street, Edinburgh, on Wednesday, July 17, at 7.30 for 8 p.m.

At the recent meeting of the Senate of the Queen's University of Belfast among those on whom it is proposed to confer honorary degrees are Sir Alexander Fleming and Dr. Frederick W. Price.

The deaths of four babies, three at Auckland and one at Wellington, from tetanus traced to talcum powder are reported by a correspondent in New Zealand. The deaths occurred in the first week of June, and the authorities at the Auckland Public Hospital traced the tetanus to the talcum powder used on the infants. Immediately the cause of the deaths was announced in the Press, the distributor of a well-known brand of Australian talcum voluntarily withdrew the preparation from the market, and the New Zealand Department of Health is now considering withdrawing all supplies of talcum for sterilization. The Director-General of Health, Dr. M. H. Watt, stated that his Department had issued notices to all hospitals and to obstetricians warning them of the position and instructing the use of zinc oxide and starch instead of talcum on new-born babies.

Nutrition and Child Welfare is a periodical published at 6d. from 28, Alva Street, Edinburgh, 2, but all communications should be sent to the London office, 70, King's Road, S.W.3. The first number contains articles on "The Chair of Child Health and Infant Nutrition," by Prof. Alan Moncrieff; on why mild forms of rickets are undetected, by Dr. Ursula Shelley; and on the scientific principles of nutrition, by Dr. R. P. Cook. The journal is intended for health visitors, school nurses, nursery matrons, and nursery school teachers.

The Ministry of Health has issued a notice (Circular 133/46) on provision of medical treatment, under the Government Evacuation Scheme, for orphans and other children without suitable homes to which to return. The arrangement under which medical treatment was provided through the Local Medical War Committees has been revised. Doctors attending billeted children will from July 1 be paid through Insurance Committees, and the basis of payment will be a capitation fee of 14s. per head per annum for treatment and medicine and appliances for unaccompanied children in billets. Part-time doctors will be appointed to hostels and residential nurseries, and provision is made for medical inspection of nurseries and for medical treatment of children in sick bays.

Prof. W. M. Mitchell, M.B., F.R.C.V.S., has been appointed Principal of the Royal (Dick) Veterinary College, Edinburgh, in succession to Sir Arthur Oliver, who retired last year. Prof. Mitchell has been on the staff of the College for over 30 years and is president-elect of the National Veterinary Medical Association. During the first world war he served as a captain in the R.A.V.C. and was awarded the Military Cross; in the second world war he served as major in the R.A.M.C. He will take up his new post on Oct. 1.

Dr. F. Stratton has been appointed director of the Ministry of Health Regional Transfusion Centre, Manchester, in place of Dr. J. F. Wilkinson, who has resigned.

An Order dated June 14 places pethidine and its salts in Part I of the Poisons List and on the first schedule.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Atiology Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate Westcent, London*.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Fistula-in-ano

Q.—*In a case of fistula-in-ano the internal opening is three-quarters of the way up the lateral wall of the anal canal, and seems to be almost at the upper margin of the internal sphincter. Is it safe to divide all the sphincter superficial to this?*

A.—The answer to this question depends upon the course which the fistulous track takes between the internal and external openings. If it happens to pass deep to the entire external sphincter, which is uncommon, then it would be very unwise to cut through the whole track, for incontinence would probably result. If the track goes between the subcutaneous and deep parts of the external sphincter, the lower part could be cut through, but the upper portion of the track might be better dealt with by a silk ligature, which will gradually cut its way through the mucosa. The questioner would do well to consult Miles's classical paper on the subject (*Proceedings of the Royal Society of Medicine*, 1931, 25, 1649).

A Senior Partner Retires

Q.—*A, who has been in the practice for over 30 years, is retiring. B, the junior partner, will be joined by C, the present assistant. Is there any legal objection to B and C retaining A's name on the stationery when sending out patients' accounts?*

A.—As A is ceasing to be a partner, to keep his name on the stationery might well amount to a misrepresentation, and suggest falsely that A's services and skill were still available in the practice, and that he was still responsible for any claims made against the firm. To do this would be legally, as well as ethically, wrong.

Continuous-drip Milk for Peptic Ulcer

Q.—*In the continuous-drip milk treatment of peptic ulcer what is the correct rate of drip and the total daily quantity? Should alkalis and atropine be administered, and, if so, how?*

A.—The continuous-drip milk treatment of peptic ulcer is usually carried out through a long rubber tube sufficiently small to pass through the nose into the stomach. It is retained in position and attached to the cheek by adhesive tape. The milk is contained in a glass jar, similar to jars used for blood transfusion, and this is connected with the tube by a glass junction with a tap, or clip, enabling the rate of flow to be controlled. About 3 pints (1.7 l.) of milk or equivalent fluid food is given each 24 hours; additional water may be given either through the reservoir or directly swallowed. Alkali in powder, or aluminium hydroxide in suspension, may be added to the milk in appropriate amounts. This type of feeding has the advantage that a specimen of the gastric contents may be withdrawn from time to time by a syringe and tested for neutrality.

Atropine is not usually employed as well, but there is no reason why it should not be. Many authorities would prefer that it should be given early each morning, dissolved in several ounces of water in order that it may act directly upon a clean gastric mucosa. Although the tube may be retained almost indefinitely, it is desirable to remove and re-pass it every 48 hours at least in order to clean it, and so avoid the risk of local inflammatory reaction.

Posterior Pituitary Extracts in Labour

Q.—At a recent postgraduate course I was informed by two obstetricians that 0.5 ml. pitocin should be given intramuscularly to the mother as soon as the baby was born. As this teaching is contrary to all I learnt as a student, I would appreciate an authoritative statement as to what the dangers of this procedure are, if any?

A.—The questioner has raised one of the most controversial points in modern obstetrics. There is a sharp difference of opinion between those who believe that an oxytocic drug—pitocin or ergometrine—should be given as soon as the child is delivered, in order to minimize blood loss in the third stage of labour and hasten delivery of the placenta, and those who believe that no oxytocic should be given until the placenta is born.

Possible dangers of the procedure include, first, the risk of causing contraction ring, or hour-glass contraction, of the uterus. If this occurs, delivery of the placenta, and perhaps even manual removal, will be impossible until the spasm relaxes. The effect of pitocin is relatively evanescent and lasts only about half an hour, after which time it is possible to deliver the placenta in most cases. Another and more serious danger is that of "pituitary shock," fortunately rare but very alarming, and perhaps fatal, when it does appear. If pitocin is given by intramuscular injection the risk is minimal, though it is greatly increased with repeated doses of posterior pituitary extract in any form. For this reason no more than a single dose should ever be injected in the third and fourth stages of labour. A third possible risk is of acute inversion of the uterus, especially if the administration of pitocin is accompanied by a too vigorous attempt to expel the placenta.

The two opposing views were put forward in the correspondence columns of the *Journal* (1944, 2, 353, and 511). The discussion was summed up by Prof. Moir (1944, 2, 606), who stated: "The administration of oxytocic drugs before the birth of the placenta has been much disputed, and personally I dislike the routine use of such methods." He goes on to mention that 5 units (0.5 ml.) of pitocin may be given into the muscle of the uterus, through the anterior abdominal wall, in cases where the uterus is flabby and the placenta has not separated after half an hour. After mentioning reports from the United States of America, recommending the injection of ergometrine by the intravenous route with the birth of the anterior shoulder, he concludes: "The method has inherent risks and should not be used outside hospital practice."

Dry Skin in the Tropics

Q.—A 21-year-old spinster has always had dry shiny skin on the backs of both hands. She has lived in the Tropics all her life, and has fair skin, very freckled and hairy over exposed areas, and is red-haired. General health is excellent. I would be grateful for advice as to treatment.

A.—The exposed skin of white persons who live in tropical or subtropical regions tends to become thin, often yellowish, and to develop pigment spots and later keratoses, which may degenerate into basal-cell new growths. This is observed in Australia, and also, on the backs of the hands, among tea planters in India and Ceylon. It has been noticed in Australia that the more severe type of change is especially liable to occur in fair or reddish complexioned people of Scottish or Ulster descent. A simple cream, and avoidance of sunlight so far as possible, is about as much as can be done for the young lady mentioned above.

Virginal Erosion of the Cervix

Q.—A nulliparous woman of 22 has had a slight mucoid vaginal discharge for six or seven years. Two gynaecologists have told her that she has a "virginal erosion." Cauterization was performed a few months ago under general anaesthesia, but the discharge persists and the erosion is still there. Is any further treatment indicated, and, if so, what? Is the condition likely to prevent conception? What are the chances of carcinoma of the cervix supervening later on?

A.—"Virginal," or "congenital," erosion of the cervix is extremely common, and is sometimes reckoned as being present in one-third of female children at birth. Its pathological

significance is therefore doubtful and there is no reason to believe that it favours the development of carcinoma in later life. Nor as a rule does it lower fertility significantly, although it may do so if it is associated with a change in cervical secretion, or if there is superadded infection. Virginal erosions are usually symptomless but sometimes do cause an increase in the natural discharge, such as appears to be present in this case. However, if it has not already been done, it might be wise to have the discharge fully examined to exclude any infection.

If the amount of discharge is not sufficient to be troublesome no treatment is required, and there would be no harm in waiting to see if fertility is affected. If, for one reason or another, further treatment is necessary, either cauterization or coagulation diathermy should be judiciously applied. It should be possible to obtain a cure by such measures, and the treatment can be carried out without anaesthesia.

Starvation and Anorexia Nervosa

Q.—Has recent clinical experience with cases of starvation led to any advance in the treatment of anorexia nervosa?

A.—Recent clinical experience with cases of starvation has emphasized the value of milk as the most effective single food-stuff. Apart from some observations made during the Bengal famine, no satisfactory results emerged from treating cases with protein hydrolysates. More success resulted from the use of plasma, but the evidence goes to show that even in advanced states of starvation a measure of digestive and absorptive power remains in the alimentary tract.

In anorexia nervosa the digestive and absorptive power of the gut is not likely to be so markedly affected. The difficulty is to retain food long enough to permit of these processes proceeding satisfactorily. It is very doubtful if protein hydrolysates, even when safe to administer intravenously, have any real place in the treatment of this condition unless as a temporary measure in a very severe case. The administration of hydrolysates intravenously might then have a beneficial effect, even apart from the psychological standpoint.

Dysaesthesia in Disseminated Sclerosis

Q.—A patient who has had disseminated sclerosis for 25 years complains of troublesome intermittent deep paraesthesiae. These are of a tingling tickling nature and affect the joints and muscles. They interfere seriously with sleep and intellectual activity. What is the cause of these symptoms and how can the condition be ameliorated?

A.—Defective myelination of projectional fibre tracts may perhaps be responsible for the dysaesthesia encountered in disseminated sclerosis. It is rare for it to be so obtrusive as to render a patient sleepless and to occasion much distress. Amelioration may be difficult, but the problem can be tackled: (1) By treatment of the disease itself—e.g., with arsenic, vitamin B, liver extract, iodides, quinine. (2) By symptomatic remedies—i.e., sedatives combined with analgesic remedies. In this connexion combinations of aspirin and phenobarbital might prove helpful. Tinct. gelsemii is also worth trying. (3) Finally, vasodilator drugs might be of assistance, as in the condition described as "jittery or restless legs" (syn.: *asthenia crurum paraesthetica*). See K. A. Ekbom, *Acta med. scand.* 1944, 118, 197.

INCOME TAX

Mortgage Outside United Kingdom

S. M. has advanced money on mortgage in Eire. He has not received interest since 1939, and has waived his right to receive it. Is he liable to British tax on this interest?

* The liability attaches to interest "arising," but where the interest has been waived, the Revenue authorities will admit exemption from the tax. S. M. should accordingly explain the facts to the tax office dealing with his income tax. Some evidence that he has given up his legal right to payment may be required.

"Initial Allowance" for Car

J. G. asks whether the initial allowance is made only when a car is bought for the first time, or does it apply also to a car bought in replacement of a former car?

* It applies to both categories.

Remittances from Indian Pay

H. S. J. inquires whether an R.A.M.C. officer serving in India on Indian rates of pay who sends money home to his bank account in England is liable to British tax, as well as Indian tax, on the pay so remitted?

* If the officer ranks as a "resident" in the U.K.—e.g., because his family are living here—the remittances are liable to British tax, except as regards a financial year during the whole of which he was absent from the United Kingdom. If the remittances are liable there will be some relief due in respect of the tax paid in India.

Assistant or Partner: Expenses

I. M. is to be a salaried assistant at an "All in" rate with no specified allowances. He is buying the house of a partner and will be responsible for maintaining the surgery there—but not drugs or instruments. What expenses can he claim?

* He can claim the expenses incurred "wholly, exclusively, and necessarily" in the performance of his duties as an assistant, and since those duties include the maintenance of the surgery, running a car, and those normally borne by a partner, it would seem that he can claim to deduct much the same amount as would be deductible under Schedule E. On the other hand, if he becomes a partner he escapes from the rather more rigid rule applying to Schedule E. (e.g., any effect of the word "necessary"), and that alternative is preferable from the income tax standpoint.

Colonial Resident in R.A.M.C.

G. T. is resident and domiciled in the West Indies. Is he liable to British tax on R.A.M.C. pay?

* Yes—if the pay is issued "out of the public revenue of the United Kingdom." (If the service had been in India and the pay issued from Indian sources it would not have been liable to British tax.)

Retirement from Practice Abroad

M. O. has practised abroad for 20 years and proposes to retire in March, 1947. He and his wife have stayed in this country recently—their stay extending into the present financial year. What is the position as regards future remittances?

* Remittances of income will be taxable but *not* remittances of capital. The mode of making the remittances appears to be immaterial. (If the recent visit was made with a view to establishing a residence here the authorities may claim tax—less "Dominion income tax relief"—on the amounts spent here during the visit.)

LETTERS, NOTES, ETC.

Wellcome Historical Medical Museum Library

Dr. E. ASHWORTH UNDERWOOD, the director of the Wellcome Historical Medical Museum, 183-193, Euston Road, London, N.W.1, asks us to announce that a catalogue of the extensive library of the museum is being prepared, but that it will be some time before this work will be published. Meanwhile, if any person who is preparing a bibliography of the works of any writer in the field of medicine or the allied sciences desires to include the location of known copies of the different works, Dr. Underwood will be pleased to send him on request a list of the various works and separate editions of that writer which are in the library of the Wellcome Historical Medical Museum, and applications should be made to him in writing. It is hoped to open the library for the use of students at an early date, and an announcement will be made to that effect, but meanwhile the above particulars will be supplied on request.

Effect of Sweets on Teeth

Miss DOROTHY M. RICHARDSON writes: My attention having been drawn to Dr. H. E. Magee's Milroy lectures (March 30, p. 475) summarizing the results of an experiment in giving to children, as well as an extra ration of sweets, chocolate biscuits to eat at night after the teeth had been cleaned, I am moved, as an interested layman, to suggest that the result—the absence of any deleterious effects upon the children's teeth—is perhaps easily explicable and in no sense destructive of the findings of the dental profession in regard to most sweets and most biscuits. For the only "chocolate biscuits" available during the war have been the kind known as "digestive"—i.e., a rather coarse wholemeal or, alternatively, oatmeal, very thinly coated with a solution of plain chocolate. Each of these three substances is easily soluble and non-adhesive, as are, also, the plain boiled sweets which have been the sole alternative to plain chocolate. To yield convincing results the experiments should surely be made with the popular fine glutinous white-flour biscuits which both clog the gums and lodge in the interstices of the teeth; and with "sweets" of the fudge, fondant, nougat, and chocolate cream variety, all, though readily soluble, apt to cling and to lodge.

Acne and Pimples

Dr. HILTON BROWN (Edinburgh) writes: Those who have examined recruits at medical boards during the past six years must have been struck by the large number of our young men who suffer from acne and pimples. Scrubbing with soap, opening the pores, and applying antiseptic ointment, which is the usual treatment prescribed in textbooks, is worse than useless. I have found the following simple treatment most effective. (1) Use no soap at all unless the face is dirty, in which case be sure to wash off all the soap. Just dip the face in tepid water and don't dry it; let the water evaporate on the skin. On no account be rough with a towel. (2) With a piece of cotton-wool sponge all over the face with methylated spirit (the usual coloured stuff) morning and night. Get someone to sponge it on the back if acne is on the back also. (3) Dust over the hair frequently with a wrung-out sponge or cloth in order to check dandruff. In most cases a few days of this treatment will make a great improvement, and a complete cure is generally rapid.

Chorea

Surg. Lieut. M. G. JACOBY, R.N.V.R., writes from Sunderland: With reference to the answer under "Any Questions?" April 27 p. 670) on calcium balance in chorea, I should like to bring to you notice a paper published by Golla and Walter in the *Practitioner* (May, 1943). According to this there are abnormal electro-encephalographic changes in the brain in chorea similar to those occurring in epilepsy. In other words, chorea may be regarded as a mid-brain epilepsy. Another point made was that "epanutin," unlike bromides and "luminal," reversed the E.C.G. appearances, giving a normal E.C.G. in epileptic cases. As a result of the above I tried a series of six chorea cases with "epanutin," not, however, getting any results to show that this drug influenced the disease. The final comment I should like to make is that cases of chorea vary in their intensity and response to treatment as much as true epilepsy. Also, the tendency is towards cure, whatever the treatment. It is therefore wrong to assume that any treatment is outstandingly successful unless a large number of cases are treated.

Dispensing by Nurses in Hospital

Mr. F. C. WILSON (Member of Council of the Pharmaceutical Society) writes: The death of a hospital patient through a nurse misreading a prescription sign has led to the suggestion that the traditional symbols of the apothecary should now give way to the metric system. In fact the metric system is coming into use, and its further employment depends on the extent to which physicians choose to adopt it in writing prescriptions. How drugs are measured is not, however, the real issue. It is as easy to slip up over a decimal point as over a drachm loop. The real issue is who measures them. In the case in question a pharmacist would have realized that the quantity was greatly in excess of the proper dose. The law should forbid the dispensing of potent drugs in hospitals except by, or under the supervision of, a pharmacist, and so dispense with the incompetent dispenser.

Records of Longevity

Dr. ANDREW ROBERTSON (Ayrshire) writes: Here in tabular form is a record of longevity which may interest readers. Can any of them beat it?

Column 1		Column 2		Column 3	
Age	Died	Age	Died	Age	Died
82	1849	79	1876	Husband:	84 1902
84	1865	85	1886	Wife:	75 1906
Parents of Col. 3 husband		Parents of Col. 3 wife			
Their Family		I know of two sons and three daughters. All had grown-up families when they died		Their Family	
Age	Died			Age	Died
79	1883			Firstborn:	80 1935
66	1873			Third:	80 1937
75	1885			Tenth:	77 25/2/1946
65	1879			Only eleven out of fourteen offspring now alive. The youngest is 71	
80	1895				
84	1902 (See Col. 3)				
81	1901				
32	1856				

Identity Numbers for Health Records?

Dr. W. W. ANDERSON (London, N.W.) writes: I was intrigued by Mr. C. Hamblen-Thomas's suggestion (June 8, p. 902) that identity numbers be impressed on the buttocks of infants. He would he deal with the 45 million people of this country not treated? In the absence of sartorial distinction to-day the prospect of exposure of buttocks in order to establish identity and determine sex would be, to say the least, embarrassing. I can well imagine that some would rather be unconscious during the process of providing identity, and subsequently remain so. Nevertheless, there are possibilities in the idea; the same locality might be used for the hidden display of much more useful information.
